$$= 3.6 + \frac{(1.5)^2}{2} = 7.134 \text{ m}^2$$

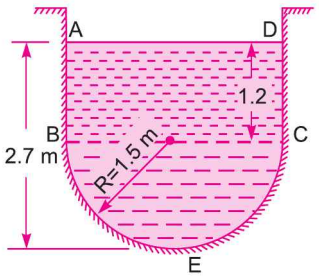

Fig. 16.5

Wetted perimeter, $P = AB + BEC + CD$

$$= 1.2 + \pi R + 1.2 = 1.2 + \pi \times 1.5 + 1.2 = 7.1124 \text{ m}$$

$\therefore$ Hydraulic mean depth, $m = \frac{A}{P} = \frac{7.134}{7.1124} = 1.003$

The discharge, Q is given by equation (16.5) as

$$Q = AC\sqrt{mi}$$

$$= 7.134 \times 60 \times \sqrt{1.003 \times \frac{1}{2000}} = \mathbf{9.585 \text{ m}^3\text{/s. Ans.}}$$

Problem 16.7 *Find the rate of flow of water through a V-shaped channel as shown in Fig. 16.6. Take the value of C = 55 and slope of the bed 1 in 2000.*

Solution. Given :

Chezy's constant, $C = 55$

Bed slope, $i = \frac{1}{1000}$

Depth of flow, $d = 4.0$ m

Angle made by each side with vertical,

i.e., $\angle ABD = \angle CBD = 30°$

From Fig. 16.6, we have

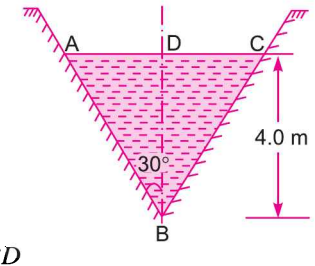

Fig. 16.6

Area, A = Area of ABC

$$= 2 \times \text{Area } ABD = \frac{2 \times AD \times BD}{2} = AD \times BD$$

$$= BD \tan 30° \times BD \qquad \left(\because \tan 30° = \frac{AD}{BD},\ AD = BD \tan 30°\right)$$

$$= 4 \tan 30° \times 4 = 9.2376 \text{ m}^2$$

Wetted perimeter, $P = AB + BC = 2AB \qquad (\because AB = BC)$

$$= 2\sqrt{BD^2 + AD^2} = 2\sqrt{4.0^2 + (4 \tan 30°)^2}$$

$$= 2\sqrt{16.0 + 5.333} = 9.2375 \text{ m}.$$

$\therefore$ Hydraulic mean depth, $m = \dfrac{A}{P} = \dfrac{9.2376}{9.2375} = 1.0$ m

Using equation (16.5) for discharge,

$$Q = AC\sqrt{mi} = 9.2376 \times 55 \times \sqrt{1 \times \frac{1}{1000}} = \mathbf{16.066\ m^3/s.\ Ans.}$$

▶ 16.4 EMPIRICAL FORMULAE FOR THE VALUE OF CHEZY'S CONSTANT

Equation (16.4) is known Chezy's formula after the name of a French Engineer, Antoine Chezy who developed this formula in 1975. In this equation C is known as Chezy's constant, which is not a dimensionless co-efficient. The dimension of C is

$$= \frac{V}{\sqrt{mi}} = \frac{L/T}{\sqrt{\frac{A}{P} i}} = \frac{L/T}{\sqrt{\frac{L^2}{L} i}} = \frac{L}{T\sqrt{Li}} = \frac{\sqrt{L}}{T}$$

$$= L^{1/2}T^{-1} \qquad \{ i \text{ is dimensionless}\}$$

Hence the value of C depends upon the system of units. The following are the empirical formulae, after the name of their inventors, used to determine the value of C:

1. Bazin formula (In MKS units) : $C = \dfrac{157.6}{1.81 + \dfrac{K}{\sqrt{m}}}$ ...(16.6)

where K = Bazin's constant and depends upon the roughness of the surface of channel, whose values are given in Table 16.1.

m = Hydraulic mean depth or hydraulic radius.

2. Ganguillet-Kutter Formula. The value of C is given in MKS unit as

$$C = \frac{23 + \frac{0.00155}{i} + \frac{1}{N}}{1 + \left(23 + \frac{0.00155}{i}\right)\frac{N}{\sqrt{m}}} \quad ...(16.7)$$

where N = Roughness co-efficient which is known as Kutter's constant, whose value for different surfaces are given in Table 16.2

i = Slope of the bed

m = Hydraulic mean depth.

Table 16.1 Values of K in the Bazin's Formula

S. No.	*Nature of Channel inside surface*	*Value of K*
1.	Smooth cemented or planned wood	0.11
2.	Brick or concrete or unplanned wood	0.21
3.	Rubble masonary or Ashlar or poor brick work	0.83
4.	Earthen channel of very good surface	1.54
5.	Earthen channel of ordinary surface	2.36
6.	Earthen channel of rough surface	3.17

Table 16.2 Value of N in the Ganguillet-Kutter Formula

S. No.	*Nature of Channel inside surface*	*Value of N*
1.	Very smooth surface of glass, plastic or brass	0.010
2.	Smooth surface of concrete	0.012
3.	Rubble masonary or poor brick work	0.017
4.	Earthen channels neatly excavated	0.018
5.	Earthen channels of ordinary surface	0.027
6.	Earthen channels of rough surface	0.030
7.	Natural streams, clean and straight	0.030
8.	Natural streams with weeds, duppools etc.	0.075 to .15

3. Manning's Formula. The value of C according to this formula is given as

$$C = \frac{1}{N} m^{1/6} \quad ...(16.8)$$

where m = Hydraulic mean depth

N = Manning's constant which is having same value as Kutter's constant for the normal range of slope and hydraulic mean depth. The values of N are given in Table 16.2.

Problem 16.8 *Find the discharge through a rectangular channel 2.5 m wide, having depth of water 1.5 m and bed slope as 1 in 2000. Take the value of k = 2.36 in Bazin's formula.*

Solution. Given :

Width of channel, $b = 2.5$ m

Depth of flow, $d = 1.5$ m

$\therefore$ Area, $A = b \times d = 2.5 \times 1.5 = 3.75$ m^2

Wetted Perimeter, $P = d + b + d = 1.5 + 2.5 + 1.5 = 5.5$ m

$\therefore$ Hydraulic mean depth, $m = \frac{A}{P} = \frac{3.75}{5.50} = 0.682$

Bed slope, $i = \frac{1}{2000}$

Bazin's constant, $K = 2.36$

Using Bazin's formula given by equation (16.6), as

$$C = \frac{157.6}{1.81 + \frac{K}{\sqrt{m}}} = \frac{157.6}{1.81 + \frac{2.36}{\sqrt{0.682}}} = 33.76$$

Discharge, Q is given by equation (16.5), as

$$Q = AC\sqrt{mi}$$

$$= 3.75 \times 33.76 \times \sqrt{0.682 \times \frac{1}{2000}} = \mathbf{2.337\ m^3/s.\ Ans.}$$

Problem 16.9 *Find the discharge through a rectangular channel 14 m wide, having depth of water 3 m and bed slope 1 in 1500. Take the value of N = 0.03 in the Kutter's formula.*

Solution. Given :

Width of channel, $b = 4$ m

Depth of water, $d = 3$ m

Bed slope, $i = \frac{1}{1500} = 0.000667$

Kutter's constant, $N = 0.03$

Area of flow, $A = b \times d = 4 \times 3 = 12\ m^2$

Wetted perimeter, $P = d + b + d = 3 + 4 + 3 = 10$ m

$\therefore$ Hydraulic mean depth, $m = \frac{A}{P} = \frac{.12}{10} = 1.2$ m

Using Kutter's formula given by equation (16.7), as

$$C = \frac{23 + \frac{.00155}{i} + \frac{1}{N}}{1 + \left(23 + \frac{.00155}{i}\right) \times \frac{N}{\sqrt{m}}} = \frac{23 + \frac{.00155}{.000667} + \frac{1}{.03}}{1 + \left(23 + \frac{.00155}{.000667}\right) \times \frac{.03}{\sqrt{1.20}}}$$

$$= \frac{23 + 2.3238 + 33.33}{1 + (23 + 2.3238) \times .03286} = \frac{58.633}{1.832} = 32.01$$

Discharge, Q is given by equation (16.5), as

$$Q = AC\sqrt{mi} = 12 \times 32.01 \times \sqrt{12 \times .000667} = \mathbf{10.867\ m^3/s.\ Ans.}$$

Problem 16.10 *Find the discharge through a rectangular channel of width 2 m, having a bed slope of 4 in 8000. The depth of flow is 1.5 m and take the value of N in Manning's formula as 0.012.*

Solution. Given :

Width of the channel, $b = 2$ m

Depth of the flow, $d = 1.5$ m

$\therefore$ Area of flow, $A = b \times d = 2 \times 1.5 = 3.0\ m^2$

Wetted perimeter, $P = b + d + d = 2 + 1.5 + 1.5 = 5.0$ m

$\therefore$ Hydraulic mean depth, $m = \frac{A}{P} = \frac{3.0}{5.0} = 0.6$

Bed slope , $i = 4 \text{ in } 8000 = \frac{4}{8000} = \frac{1}{2000}$

Value of N $= 0.012$

Using Manning's formula, given by equation (16.8), as

$$C = \frac{1}{N} m^{1/6} = \frac{1}{0.012} \times 0.6^{1/6} = 76.54$$

Discharge, Q is given by equation (16.5), as

$$Q = AC\sqrt{mi}$$

$$= 3.0 \times 76.54 \sqrt{0.6 \times \frac{1}{2000}} \text{ m}^2/\text{s} = \mathbf{3.977\ m^3/s.\ Ans.}$$

Problem 16.11 *Find the bed slope of trapezoidal channel of bed width 4 m, depth of water 3 m and side slope of 2 horizontal to 3 vertical, when the discharge through the channel is 20 m^3/s.*

Take Manning's $N = 0.03$ in Manning's formula $C = \frac{1}{N} m^{1/6}$.

Solution. Given :

Bed width, $b = 4$ cm

Depth of flow, $d = 3$ m

Side slope $= 2$ hor. to 3 vert.

Discharge, $Q = 20.0 \text{ m}^3/\text{s}$

Manning's, $N = 0.03$

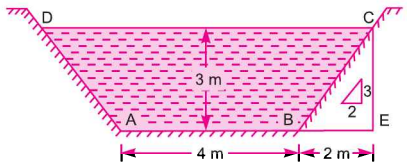

Fig. 16.7

From Fig. 16.7, we have

Distance, $BE = d \times \frac{2}{3} = 3 \times \frac{2}{3} = 2$ m

$\therefore$ Top width, $CD = AB + 2BE$

$= 4 + 2 \times 2 = 8.0$ m

$\therefore$ Area of flow, $A =$ Area of trapezoidal section $ABCD$

$$= \frac{(AB + CD)}{2} \times d = \frac{(4 + 8)}{2} \times 3 = 18 \text{ m}^2$$

Wetted perimeter, $P = AD + AB + BC = AB + 2BC$ ($\because$ $AD = BC$)

$$= 4.0 + 2\sqrt{BE^2 + EC^2} = 4.0 + 2\sqrt{2^2 + 3^2} = 4.0 + 2 \times \sqrt{13} = 11.21 \text{ m}$$

$\therefore$ Hydraulic mean depth, $m = \frac{A}{P} = \frac{18}{11.21} = 1.6057$

Using Manning's formula, $C = \frac{1}{N} m^{1/6} = \frac{1}{0.03} \times (1.6057)^{1/6} = 36.07$

Using equation (16.5) for discharge,

$$Q = AC\sqrt{mi} = 18 \times 36.07 \times \sqrt{1.6057 \times i} \quad \text{or } 20.0 = 822.71\sqrt{i}$$

$$\therefore \quad i = \left(\frac{20.0}{822.71}\right)^2 = 0.0005909 = \frac{\mathbf{1}}{\mathbf{1692}}. \textbf{ Ans.}$$

Problem 16.12 *Find the diameter of a circular sewer pipe which is laid at a slope of 1 in 8000 and carries a discharge of 800 litres/s when flowing half full. Take the value of Manning's N = 0.020.*

Solution. Given :

Slope of pipe, $i = \frac{1}{8000}$

Discharge, $Q = 800$ litres/s $= 0.8$ m^3/s

Manning's, $N = 0.020$

Let the dia. of sewer pipe, $= D$

Depth of flow, $d = \frac{D}{2}$

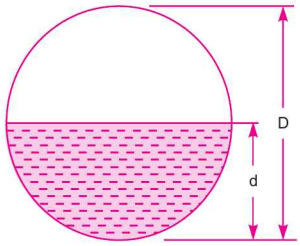

Fig. 16.8

$\therefore$ Area of flow, $A = \frac{\pi}{4}D^2 \times \frac{1}{2} = \frac{\pi D^2}{8}$

Wetted perimeter, $P = \frac{\pi D}{2}$

$\therefore$ Hydraulic mean depth, $m = \frac{A}{P} = \frac{\frac{\pi D^2}{8}}{\pi D/2} = \frac{D}{4}$

Using Manning's formula given by equation (16.8), $C = \frac{1}{N} m^{1/6}$

The discharge, Q through pipe is given by equation (16.6), as

$$Q = AC\sqrt{mi}$$

$$= \frac{\pi D^2}{8} \times \frac{1}{N} m^{1/6}\sqrt{mi}$$

or $$0.80 = \frac{\pi}{8}D^2 \times \frac{1}{.020} \times m^{1/6} \times m^{1/2} \times \sqrt{i}$$

$$= \frac{\pi}{8}D^2 \times \frac{1}{.020} m^{(1/6 + 1/2)} \times \sqrt{\frac{1}{8000}} = \frac{\pi}{8}D^2 \times \frac{1}{.020} \times m^{2/3} \times 0.01118$$

$$= 0.2195 \times D^2 \times \left(\frac{D}{4}\right)^{2/3} \qquad \left(\because \quad m = \frac{D}{4}\right)$$

$$= \frac{.2195}{4^{2/3}} \times D^2 \times D^{2/3} = 0.0871\, D^{8/3}$$

or $$D^{8/3} = \frac{0.80}{.0871} = 9.1848$$

$\therefore$ $$D = (9.1848)^{3/8} = (9.1848)^{0.375} = \textbf{2.296 m. Ans.}$$

▶ 16.5 MOST ECONOMICAL SECTION OF CHANNELS

A section of a channel is said to be most economical when the cost of construction of the channel is minimum. But the cost of construction of a channel depends upon the excavation and the lining. To keep the cost down or minimum, the wetted perimeter, for a given discharge, should be minimum. This condition is utilized for determining the dimensions of a economical sections of different form of channels.

Most economical section is also called the best section or most efficient section as the discharge, passing through a most economical section of channel for a given cross-sectional area (A), slope of the bed (i) and a resistance co-efficient, is maximum. But the discharge, Q is given by equation (16.5) as

$$Q = AC\sqrt{mi} = AC\sqrt{\frac{A \times i}{P}} \qquad \left(\because \quad m = \frac{A}{P}\right)$$

For a given A, i and resistance co-efficient C, the above equation is written as

$$Q = K\frac{1}{\sqrt{P}}, \quad \text{where } K = AC\sqrt{Ai} = \text{constant}$$

Hence the discharge, Q will be maximum, when the wetted perimeter P is minimum. This condition will be used for determining the best section of a channel *i.e.*, best dimensions of a channel for a given area.

The conditions to be most economical for the following shapes of the channels will be considered :

1. Rectangular Channel, 2. Trapezoidal Channel, and 3. Circular Channel.

16.5.1 Most Economical Rectangular Channel. The condition for most economical section, is that for a given area, the perimeter should be minimum. Consider a rectangular channel as shown in Fig. 16.9

Let b = width of channel,

d = depth of the flow,

$\therefore$ Area of flow, $A = b \times d$ ...(*i*)

Wetted perimeter, $P = d + b + d = b + 2d$ ...(*ii*)

From equation (*i*), $b = \dfrac{A}{d}$

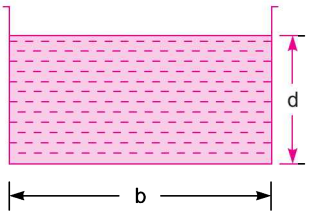

Fig. 16.9 *Rectangular channel.*

Substituting the value of b in (*ii*),

$$P = b + 2d = \frac{A}{d} + 2d \qquad ...(iii)$$

For most economical section, P should be minimum for a given area.

or $$\frac{dP}{d(d)} = 0$$

Differentiating the equation (*iii*) with respect to d and equating the same to zero, we get

$$\frac{d}{d(d)}\left[\frac{A}{d} + 2d\right] = 0 \quad \text{or} \quad -\frac{A}{d^2} + 2 = 0 \quad \text{or} \quad A = 2d^2$$

But $A = b \times d$, $\therefore$ $b \times d = 2d^2$ or $b = 2d$ ...(16.9)

Now hydraulic mean depth, $m = \dfrac{A}{P} = \dfrac{b \times d}{b + 2d}$ $(\because \quad A = bd,\ P = b + 2d)$

$$= \frac{2d \times d}{2d + 2d} \qquad (\because \quad b = 2d)$$

$$= \frac{2d^2}{4d} = \frac{d}{2} \qquad \ldots(16.10)$$

From equations (16.9) and (16.10), it is clear that rectangular channel will be most economical when:
(*i*) Either $b = 2d$ means width is two times depth of flow.

(*ii*) Or $m = \frac{d}{2}$ means hydraulic depth is half the depth of flow.

Problem 16.13 *A rectangular channel of width, 4 m is having a bed slope of 1 in 1500. Find the maximum discharge through the channel. Take value of C = 50.*

Solution. Given :

Width of channel, $b = 4$ m

Bed slope, $i = \frac{1}{1500}$

Chezy's constant, $C = 50$

Discharge will be maximum, when the channel is most economical. The conditions for most economical rectangular channel are :

(*i*) $b = 2d$ or $d = \frac{b}{2} = \frac{4}{2} = 2.0$ m

(*ii*) $m = \frac{d}{2} = \frac{2}{2} = 1.0$ m

$\therefore$ Area of most economical rectangular channel, $A = b \times d = 4.0 \times 2.0 = 8$ m^2

Using equation (16.5) for discharge as

$$Q = AC\sqrt{mi} = 8.0 \times 50 \times \sqrt{1.0 \times \frac{1}{1500}} = \mathbf{10.328\ m^3/s.\ Ans.}$$

Problem 16.14 *A rectangular channel carries water at the rate of 400 litres/s when bed slope is 1 in 2000. Find the most economical dimensions of the channel if C = 50.*

Solution. Given :

Discharge, $Q = 400$ litres/s $= 0.4$ m^3/s

Bed slope, $i = \frac{1}{2000}$

Chezy's constant, $C = 50$

For the rectangular channel to be most economical,

(*i*) Width, $b = 2d$

(*ii*) Hydraulic mean depth, $m = \frac{d}{2}$

$\therefore$ Area of flow, $A = b \times d = 2d \times d = 2d^2$

Using equation (16.5) for discharge,

$$Q = AC\sqrt{mi}$$

or $$0.4 = 2d^2 \times 50 \times \sqrt{\frac{d}{2} \times \frac{1}{2000}} = 2 \times 50 \times \sqrt{\frac{1}{2 \times 2000}}\, d^{5/2} = 1.581\, d^{5/2}$$

$$\therefore \quad d^{5/2} = \frac{0.4}{1.581} = 0.253$$

$$\therefore \quad d = (.253)^{2/5} = \mathbf{0.577\ m.\ Ans.}$$

$$b = 2d = 2 \times .577 = \mathbf{1.154\ m.\ Ans.}$$

Problem 16.15 *A rectangular channel 4 m wide has depth of water 1.5 m. The slope of the bed of the channel is 1 in 1000 and value of Chezy's constant C = 55. It is desired to increase the discharge to a maximum by changing the dimensions of the section for constant area of cross-section, slope of the bed and roughness of the channel. Find the new dimensions of the channel and increase in discharge.*

Solution. Given :

Width of channel, $b = 4.0$ m

Depth of flow, $d = 1.5$ m

$\therefore$ Area of flow, $A = b \times d = 4 \times 1.5 = 6.0\ \text{m}^2$

Slope of bed, $i = \frac{1}{1000}$

Chezy's constant, $C = 55$

Wetted perimeter, $P = d + b + d = 1.5 + 4 + 1.5 = 7.0$ m

$\therefore$ Hydraulic mean depth, $m = \frac{A}{P} = \frac{4.0}{7.0} = 0.857$

The discharge, Q is given by $Q = AC\sqrt{mi} = 6.0 \times 55\sqrt{0.857 \times \frac{1}{1000}} = 9.66\ \text{m}^3/\text{s}$ ...(*i*)

For maximum discharge for a given area, slope of bed and roughness we proceed as :

Let b' = new width of channel

d' = new depth of flow

Then, Area, $A = b' \times d'$, where A = constant = 6.0 m^2

$\therefore \quad b' \times d' = 6.0$ ...(*ii*)

Also for maximum discharge $b' = 2d'$ ...(*iii*)

Substituting the value of b' in equation (*ii*), we have

$$2d' \times d' = 6.0 \text{ or } d'^2 = \frac{6.0}{2} = 3.0$$

$$\therefore \quad d' = \sqrt{3} = 1.732$$

Substituting the value of d' in (*iii*), we get

$$b' = 2 \times 1.732 = 3.464$$

$\therefore$ New dimensions of the channel are

Width, $b' = \mathbf{3.464\ m.\ Ans.}$

Depth, $d' = \mathbf{1.732\ m.\ Ans.}$

Wetted perimeter, $P' = d' + b' + d' = 1.732 + 3.464 + 1.732 = 6.928$

$\therefore$ Hydraulic mean depth, $m' = \frac{A}{P'} = \frac{6.0}{6.928} = 0.866$ m

(New hydraulic mean depth, m' corresponds to the condition of maximum discharge. And hence also equal to

$$\frac{d'}{2} = \frac{1.732}{2} = 0.866 \text{ m})$$

Max. discharge, Q', is given by $Q' = AC\sqrt{m'i} = 6.0 \times 55 \times \sqrt{0.866 \times \frac{1}{1000}} = 9.71 \text{ m}^3/\text{s}$ ...(*iv*)

∴ Increase in discharge $= Q' - Q = 9.71 - 9.66 =$ **0.05 m³/s. Ans.**

16.5.2 Most Economical Trapezoidal Channel. The trapezoidal section of a channel will be most economical, when its wetted perimeter is minimum. Consider a trapezoidal section of channel as shown in Fig. 16.10.

Let b = width of channel at bottom,
d = depth of flow,
θ = angle made by the sides with horizontal,

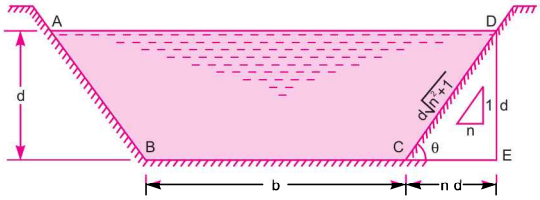

Fig. 16.10 *Trapezoidal section.*

(*i*) The side slope is given as 1 vertical to n horizontal.

∴ Area of flow, $A = \frac{(BC + AD)}{2} \times d = \frac{b + (b + 2nd)}{2} \times d$ ($\because$ $AD = b + 2nd$)

$$= \frac{2b + 2nd}{2} \times d = (b + nd) \times d \quad ...(i)$$

$$\therefore \quad \frac{A}{d} = b + nd$$

$$\therefore \quad b = \frac{A}{d} - nd \quad ...(ii)$$

Now wetted perimeter, $P = AB + BC + CD = BC + 2CD$ ($\because$ $AB = CD$)

$$= b + 2\sqrt{CE^2 + DE^2} = b + 2\sqrt{n^2d^2 + d^2} = b + 2d\sqrt{n^2 + 1} \quad ...(iia)$$

Substituting the value of b from equation (*ii*), we get

$$P = \frac{A}{d} - nd + 2d\sqrt{n^2 + 1} \quad ...(iii)$$

For most economical section, P should be minimum or $\frac{dP}{d(d)} = 0$

∴ Differentiating equation (*iii*) with respect to d and equating it equal to zero, we get

$$\frac{d}{d(d)}\left[\frac{A}{d} - nd + 2d\sqrt{n^2 + 1}\right] = 0$$

or $$-\frac{A}{d^2} - n + 2\sqrt{n^2 + 1} = 0 \quad (\because \ n \text{ is constant})$$

or $$\frac{A}{d^2} + n = 2\sqrt{n^2+1}$$

Substituting the value of A from equation (i) in the above equation,

$$\frac{(b+nd)d}{d^2} + n = 2\sqrt{n^2+1} \quad \text{or} \quad \frac{b+nd}{d} + n = 2\sqrt{n^2+1}$$

or $$\frac{b+nd+nd}{d} = \frac{b+2nd}{d} = 2\sqrt{n^2+1} \quad \text{or} \quad \frac{b+2nd}{2} = d\sqrt{n^2+1} \qquad ...(16.11)$$

But from Fig. 16.10, $\frac{b+2nd}{2}$ = Half of top width

and $d\sqrt{n^2+1} = CD$ = one of the sloping side

Equation (16.11) is the required condition for a trapezoidal section to be most economical, which can be expressed as half of the top width must be equal to one of the sloping sides of the channel.

(*ii*) **Hydraulic mean depth**

Hydraulic mean depth, $m = \frac{A}{P}$

Value of A from (i), $A = (b + nd) \times d$

Value of P from (iia), $P = b + 2d\sqrt{n^2+1} = b + (b + 2nd)$ ($\because$ From equation (16.11) $b + 2nd = 2d\sqrt{n^2+1}$)

$= 2b + 2nd = 2(b + nd)$

$\therefore$ Hydraulic mean depth, $m = \frac{A}{P} = \frac{(b+nd)d}{2(b+nd)} = \frac{d}{2}$ ...(16.12)

Hence for a trapezoidal section to be most economical hydraulic mean depth must be equal to half the depth of flow,

(*iii*) The three sides of the trapezoidal section of most economical section are tangential to the semi-circle described on the water line. This is proved as :

Let Fig. 16.11 shows the trapezoidal channel of most economical section.

Let θ = angle made by the sloping side with horizontal, and

O = the centre of the top width, AD.

Draw OF perpendicular to the sloping side AB.

ΔOAF is a right-angled triangle and angle $OAF = \theta$

$\therefore$ $\sin\theta = \frac{OF}{OA}$ $\therefore$ $OF = AO \sin\theta$ ...(iv)

In ΔAEB, $\sin\theta = \frac{AE}{AB} = \frac{d}{\sqrt{d^2 + n^2d^2}}$

$= \frac{d}{d\sqrt{1+n^2}} = \frac{1}{\sqrt{1+n^2}}$

Substituting $\sin\theta = \frac{1}{\sqrt{1+n^2}}$ in equation (iv), we get

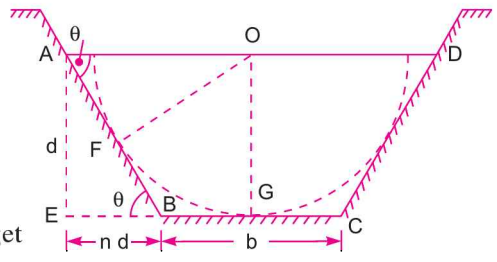

Fig. 16.11

$$OF = AO \times \frac{1}{\sqrt{1+n^2}} \qquad ...(v)$$

But AO = half of top width

$$= \frac{b+2nd}{2} = d\sqrt{n^2+1} \text{ from equation (16.11)}$$

Substituting this value of AO in equation (v),

$$OF = \frac{d\sqrt{n^2+1}}{\sqrt{n^2+1}} = d \text{ depth of flow} \qquad ...(16.13)$$

Thus, if a semi-circle is drawn with O as centre and radius equal to the depth of flow d, the three sides of most economical trapezoidal section will be tangential to the semi-circle.

Hence the conditions for the most economical trapezoidal section are:

1. $\frac{b+2nd}{2} = d\sqrt{n^2+1}$

2. $m = \frac{d}{2}$

3. A semi-circle drawn from O with radius equal to depth of flow will touch the three sides of the channel.

Problem 16.16 *A trapezoidal channel has side slopes of 1 horizontal to 2 vertical and the slope of the bed is 1 in 1500. The area of the section is 40 m^2. Find the dimensions of the section if it is most economical. Determine the discharge of the most economical section if C = 50.*

Solution. Given :

Side slope, $n = \frac{\text{Horizontal}}{\text{Vertical}} = \frac{1}{2}$

Bed slope, $i = \frac{1}{1500}$

Area of section, $A = 40 \text{ m}^2$

Chezy's constant, $C = 50$

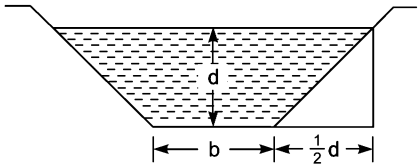

Fig. 16.12

For the most economical section, using equation (16.11)

$$\frac{b+2nd}{2} = d\sqrt{n^2+1} \quad \text{or} \quad \frac{b+2\times\frac{1}{2}\times d}{2} = d\sqrt{\left(\frac{1}{2}\right)^2+1}$$

or $$\frac{b+d}{2} = d\sqrt{\frac{1}{4}+1} = 1.118\, d$$

or $$b = 2 \times 1.118d - d = 1.236\, d \qquad ...(i)$$

But area of trapezoidal section, $A = \frac{b+(b+2nd)}{2} \times d = (b + nd)\, d$

$$= (1.236\, d + \tfrac{1}{2}\, d)\, d \qquad (\because \quad b = 1.236\, d \text{ and } n = \tfrac{1}{2})$$

$$= 1.736\, d^2$$

But $A = 40 \text{ m}^2$ (given)

$\therefore$ $40 = 1.736\, d^2$

$\therefore$ $$d = \sqrt{\frac{40}{1.736}} = \mathbf{4.80\ m.\ Ans.}$$

Substituting the value of d in equation (i), we get

$$b = 1.236 \times 4.80 = \mathbf{5.933\ m.\ Ans.}$$

Discharge for most economical section. Hydraulic mean depth for most economical section is

$$m = \frac{d}{2} = \frac{4.80}{2} = 2.40\ \text{m}$$

$\therefore$ Discharge $$Q = AC\sqrt{mi} = 40 \times 50 \times \sqrt{2.40 \times \frac{1}{1500}}$$

$$= \mathbf{80\ m^3/s.\ Ans.}$$

Problem 16.17 *A trapezoidal channel has side slopes of 3 horizontal to 4 vertical and slope of its bed is 1 in 2000. Determine the optimum dimensions of the channel, if it is to carry water at 0.5 m^3/s. Take Chezy's constant as 80.*

Solution. Given :

Side slopes $$n = \frac{\text{Horizontal}}{\text{Vertical}} = \frac{3}{4}$$

Slope of bed, $$i = \frac{1}{2000}$$

Discharge, $$Q = 0.5\ \text{m}^3/\text{s}$$

Chezy's constant, $$C = 80$$

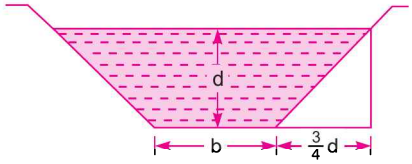

Fig. 16.13

For the most economical section, the condition is given by equation (16.11) as

$$\frac{b + 2nd}{2} = d\sqrt{n^2 + 1}, \text{ where } b = \text{width of section}, d = \text{depth of flow}$$

or $$\frac{b + 2 \times \frac{3}{4}d}{2} = d\sqrt{\left(\frac{3}{4}\right)^2 + 1} = \frac{5}{4}d \quad \text{or} \quad \frac{b + 1.5d}{2} = 1.25\ d$$

or $$b = 2 \times 1.25\ d - 1.5\ d = d \qquad ...(i)$$

For the discharge, Q, using equation (16.5) as

$$Q = AC\sqrt{mi} \qquad ...(ii)$$

But for most economical section, hydraulic mean depth $m = \frac{d}{2}$

Substituting the value of m and other known values in equation (ii)

$$0.50 = A \times 80 \times \sqrt{\frac{d}{2} \times \frac{1}{2000}} \qquad ...(iii)$$

But area of trapezoidal section is given as

$$A = (b + nd) \times d = (d + \tfrac{3}{4}d) \times d \quad (\because \text{ From } (i)\ b = d \text{ and } n = \tfrac{3}{4})$$

$$= \frac{7}{4}d^2 = 1.75\ d^2$$

Substituting the value of A in equation (iii), we get

$$0.50 = 1.75\, d^2 \times 80 \times \sqrt{\frac{d}{2} \times \frac{1}{2000}} = 2.2135\, d^{5/2}$$

$$\therefore \qquad d = \left(\frac{0.50}{2.2135}\right)^{2/5} = \textbf{0.55 m. Ans.}$$

From equation (*i*), $b = d = \textbf{0.55 m. Ans.}$

$\therefore$ Optimum dimensions of the channel are width = depth = 0.55 m.

Problem 16.18 *A trapezoidal channel with side slopes of 1 to 1 has to be designed to convey 10 m^3/s at a velocity of 2 m/s so that the amount of concrete lining for the bed and sides is the minimum. Calculate the area of lining required for one metre length of canal.*

Solution. Given :

Side slope, $n = \dfrac{\text{Horizontal}}{\text{Vertical}} = 1$

Discharge $Q = 10\ m^3/s$

Velocity, $V = 2.0$ m/s

$\therefore$ Area of flow, $A = \dfrac{\text{Discharge}}{\text{Velocity}} = \dfrac{10.0}{2.0} = 5\ m^2$ ...(*i*)

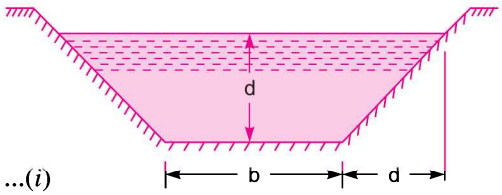

Fig. 16.14

Let b = Width of the channel

d = Depth of flow

For the amount of concrete lining for the bed and sides to be minimum the section should be most economical. But for the most economical trapezoidal section, the condition is from equation (16.11) as

Half of the top width = one of the sloping side

i.e., $$\frac{b + 2nd}{2} = d\sqrt{n^2 + 1}$$

For $n = 1$, the condition becomes

$$\frac{b + 2 \times 1d}{2} = d\sqrt{1^2 + 1} = 1.414\, d$$

or $$b = 2 \times 1.414d - 2d = 0.828\, d \qquad \text{...(}ii\text{)}$$

But area, $A = (b + nd)\, d = (0.828d + 1 \times d)\, d \qquad (\because\ b = 0.828\, d,\ n = 1)$

$= 1.828\, d^2$

Also from equation (*i*), $A = 5\ m^2$

Equating the two values of A, we get

$$5 = 1.828\, d^2 \quad \text{or} \quad d = \sqrt{\frac{5}{1.828}} = 1.6538 \simeq 1.654 \text{ m}$$

From equation (*ii*), $b = 0.828\, d = 0.828 \times 1.654 = 1.369$ m

Area of lining required for one metre length of canal

= Wetted perimeter × length of canal

$= P \times 1$

where $P = b + 2d\sqrt{n^2 + 1} = 1.369 + 2 \times 1.654\sqrt{1^2 + 1} = 6.047$ m

$\therefore$ Area of lining $= 6.047 \times 1 = \textbf{6.047 m}^2\textbf{. Ans.}$

Problem 16.19 *A trapezoidal channel has side slopes 1 to 1. It is required to discharge 13.75 m^3/s of water with a bed gradient of 1 in 1000. If unlined the value of Chezy's C is 44. If lined with concrete, its value is 60. The cost per m^3 of excavation is four times the cost per m^2 of lining. The channel is to be the most efficient one. Find whether the lined canal or the unlined canal will be cheaper. What will be the dimensions of that economical canal ?*

Solution. Given :

Side slope, $n = \frac{1}{1} = 1$

Discharge, $Q = 13.75$ m^3/s

Slope of bed, $i = \frac{1}{1000}$

For unlined, $C = 44$

For lined $C = 60$

Cost per m^3 of excavation $= 4 \times$ cost per m^2 of lining

Let the cost per m^2 of lining $= x$

Then cost per m^3 of excavation $= 4x$

As the channel is most efficient,

$\therefore$ Hydraulic mean depth, $m = \frac{d}{2}$, where d = depth of channel

Let b = width of channel

Also for the most efficient trapezoidal channel, from equation (16.11), we have

Half of top width = length of sloping side

or $$\frac{b + 2nd}{2} = d\sqrt{n^2 + 1}$$

or $$\frac{b + 2 \times 1 \times d}{2} = d\sqrt{1^2 + 1} = \sqrt{2}d$$

$\therefore$ $$b = 2 \times \sqrt{2d} - 2d = 0.828\ d \qquad ...(i)$$

Area, $$A = (b + nd) \times d = (0.828\ d + 1 \times d) \times d$$
$$= 1.828\ d^2 \qquad ...(ii)$$

1. **For unlined channel**

Value of $C = 44$

The discharge, Q is given by, $Q = A \times V = A \times C\sqrt{mi}$

or $$13.75 = 1.828\ d^2 \times 44 \times \sqrt{\frac{d}{2} \times \frac{1}{1000}} \qquad \left(\because\ A = 1.828\ d^2,\ m = \frac{d}{2}\right)$$

$$= \frac{1.828 \times 44}{\sqrt{2000}} \times d^{5/2}$$

$$d^{5/2} = \frac{13.75 \times \sqrt{2000}}{1.828 \times 44} = 7.6452$$

$\therefore$ $$d = (7.6452)^{2/5} = 2.256 \text{ m}$$

Substituting this value in equation (i), we get

$b = 0.828 \times 2.256 = 1.868$ m.

Now cost of excavation per running metre length of unlined channel

= Volume of channel × cost per m^3 of excavation

= (Area of channel × 1) × $4x$ = $[(b + nd) \times d \times 1] \times 4x$

= $(1.868 + 1 \times 2.256) \times 2.256 \times 1 \times 4x = 37.215\ x$ ...(*iii*)

2. **For lined channels**

Value of $C = 60$

The discharge is given by the equation, $Q = A \times C \times \sqrt{mi}$

Substituting the value of A from equation (*ii*) and value of $m = \frac{d}{2}$, we get

$$13.75 = 1.828\ d^2 \times 60 \times \sqrt{\frac{d}{2} \times \frac{1}{1000}} \qquad (\because \quad Q = 13.75)$$

$$= 1.828 \times 60 \times \frac{1}{\sqrt{2000}} \times d^{5/2}$$

$$\therefore \qquad d^{5/2} = \frac{13.75 \times \sqrt{2000}}{1.828 \times 60} = 5.606$$

$$\therefore \qquad d = (5.606)^{2/5} = 1.992 \text{ m}$$

Substituting this value in equation (*i*), we get

$b = 0.828 \times 1.992 = 1.649$ m

In case of lined channel, the cost of lining as well as cost of excavation is to be considered.

Now cost of excavation = (Volume of channel) × cost per m^3 of excavation

= $(b + nd) \times d \times 1 \times 4x$

= $(1.649 + 1 \times 1.992) \times 1.992 \times 1 \times 4x = 29.01\ x$

Cost of lining = Area of lining × cost per m^2 of lining

= (Perimeter of lining × 1) × x

= $(b + 2d\sqrt{1+n^2}) \times 1 \times x = (1.649 + 2 \times 1.992\sqrt{1+1^2}) \times 1 \times x$

= $(1.649 + 2 \times 1.992 \times \sqrt{2})\ x = 7.283\ x$

$\therefore$ Total cost = $29.01x + 7.283x = 36.293x$

The total cost of lined channel is $36.293x$ whereas the total cost of unlined channel is $37.215x$. Hence lined channel will be cheaper. The dimensions are $b = 1.649$ m and $d = 1.992$ m. **Ans.**

Problem 16.20 *An open channel of most economical section, having the form of a half hexagon with horizontal bottom is required to give a maximum discharge of 20.2 m^3/s of water. The slope of the channel bottom is 1 in 2500. Taking Chezy's constant, C = 60 in Chezy's equation, determine the dimensions of the cross-section.*

Solution. Given :

Maximum discharge, $Q = 20.2\ m^3/s$

Bed slope, $i = \frac{1}{2500}$

Chezy's constant, $C = 60$

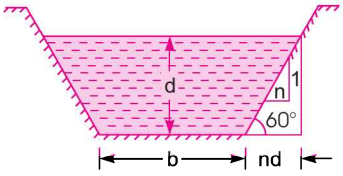

Fig. 16.15

Channel is the form of a half hexagon as shown in Fig. 16.15. This means that the angle made by the sloping side with horizontal will be 60°.

$$\therefore \qquad \tan\theta = \tan 60° = \sqrt{3} = \frac{1}{n}$$

$$\therefore \qquad n = \frac{1}{\sqrt{3}}$$

Let b = width of the channel, d = depth of the flow.

As the channel given is of most economical section, hence the condition given by equations (16.11) and (16.12) should be satisfied *i.e.*,

Half of the top width = one of the sloping side

And hydraulic mean depth = half of depth of flow

From equation (16.11), $\dfrac{b + 2nd}{2} = d\sqrt{n^2 + 1}$

For $n = \dfrac{1}{\sqrt{3}}$, $\qquad \dfrac{b + 2 \times \dfrac{1d}{\sqrt{3}}}{2} = d\sqrt{\left(\dfrac{1}{\sqrt{3}}\right)^2 + 1} = \dfrac{2d}{\sqrt{3}}$

or $\qquad \dfrac{\sqrt{3}b + 2d}{2\sqrt{3}} = \dfrac{2d}{\sqrt{3}} \quad \text{or} \quad \dfrac{\sqrt{3}b + 2d}{2} = 2d$

$$\therefore \qquad b = \frac{2 \times 2d - 2d}{\sqrt{3}} = \frac{2d}{\sqrt{3}} \qquad \ldots(i)$$

Area of flow, $\qquad A = (b + nd)\, d = \left(\dfrac{2}{\sqrt{3}}d + \dfrac{d}{\sqrt{3}}\right)d \qquad \left(\because\ n = \dfrac{1}{\sqrt{3}}, b = \dfrac{2d}{\sqrt{3}}\right)$

$$= \frac{3}{\sqrt{3}}d^2 = \sqrt{3}d^2$$

From equation (16.12) $\qquad m = \dfrac{d}{2}$

Using equation (16.5) for discharge Q as

$$Q = AC\sqrt{mi} \quad \text{or} \quad 20.2 = \sqrt{3}\ d^2 \times 60 \times \sqrt{\frac{d}{2} \times \frac{1}{2500}} = 1.4694\ d^{5/2}$$

$$\therefore \qquad d^{5/2} = \frac{20.2}{1.4696} = 13.745$$

$$\therefore \qquad d = (13.745)^{2/5} = \mathbf{2.852\ m.\ Ans.}$$

Substituting this value in equation (i), we get

$$b = \frac{2d}{\sqrt{3}} = \frac{2}{\sqrt{3}} \times 2.852 = \mathbf{3.293\ m.\ Ans.}$$

Problem 16.21 *A trapezoidal channel to carry 142 m^3/minute of water is designed to have a minimum cross-section. Find the bottom width and depth if the bed slope is 1 in 1200, the side slopes at 45° and Chezy's co-efficient = 55.*

Solution. Given : Discharge, $Q = 142 \text{ m}^3/\text{min.} = \frac{142}{60} = 2.367 \text{ m}^3/\text{s}$

Bed slope, $i = 1 \text{ in } 1200 = \frac{1}{1200}$

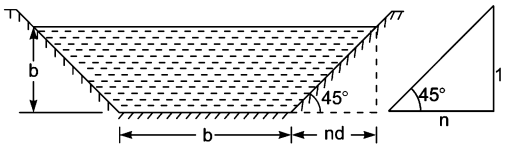

Fig. 16.16

Side slope, $\theta = 45°$

$\therefore \quad \tan\theta = \frac{1}{n}$ or $\tan 45° = \frac{1}{n}$

$\therefore \quad 1 = \frac{1}{n}$ or $n = 1$

Chezy's constant, $C = 55$

Let b = Width of the channel, d = Depth of the flow.

As the channel is to be designed for a minimum cross-section (*i.e.*, channel is of most economical section), the conditions given by equations (16.11) and (16.12) should be satisfied *i.e.*,

(*i*) Half of top with = Length of sloping side

(*ii*) Hydraulic mean depth = Half of depth of flow

From equation (16.11), $\frac{b + 2nd}{2} = d\sqrt{n^2 + 1}$

or $\frac{b + 2 \times 1 \times d}{2} = d\sqrt{1^2 + 1}$ ($\because \ n = 1$)

or $b + 2d = 2\sqrt{2d} = 2 \times 1.414\, d = 2.828\, d$

$\therefore \quad b = 2.828\, d - 2d = 0.828\, d$ ...(*i*)

Now using equation (16.5) for discharge Q, we get

$$Q = A \,.\, C \,.\, \sqrt{mi}$$

or $2.367 = (b + nd)\, d \times 55\sqrt{\frac{d}{2} \times \frac{1}{1200}}$ $\left(\because \ A = (b + nd) \times d \text{ and } m = \frac{d}{2}\right)$

$= (0.828d \times 1 \times d)\, d \times 55\sqrt{\frac{d}{2400}}$ ($\because \ b = 0.828d$)

$= (1.828d) \times d \times 55\sqrt{\frac{d}{2400}} = 2.052\, d^{5/2}$

$\therefore \quad d = \left(\frac{2.367}{2.052}\right)^{2/5} = 1.058 \simeq \mathbf{1.06 \text{ m. Ans.}}$

Substituting this value in equation (*i*), we get

$b = 0.828 \times 1.06 = \mathbf{0.877 \text{ m. Ans.}}$

Problem 16.22 *A trapezoidal channel with side slopes of 3 horizontal to 2 vertical has to be designed to convey 10 m^3/s at a velocity of 1.5 m/s, so that the amount of concrete lining for the bed and sides is minimum. Find*

(i) the wetted perimeter, and

(ii) slope of the bed if Manning's N = 0.014 in the formula $C = \frac{1}{N} \times m^{1/6}$

Solution. (*i*) Given :

Side slope, $n = \frac{\text{Horizontal}}{\text{Vertical}} = \frac{3}{2} = 1.5$

Discharge, $Q = 10\ m^3/s$

Velocity, $V = 1.5$ m/s

Manning's constant, $N = .014$

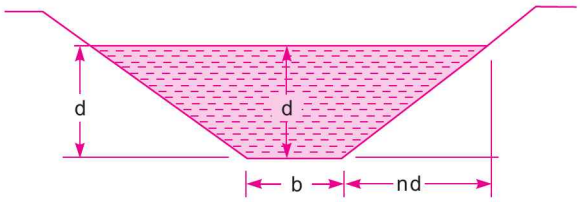

Fig. 16.17

Let b = width of the channel, d = depth of the flow.

The amount of concrete lining for the bed and sides will be minimum, when the section is most economical. For most economical trapezoidal section, the condition is given by equation (16.11) as

$$\frac{b + 2nd}{2} = d\sqrt{n^2 + 1}$$

For $n = 1.5$, $\frac{b + 2 \times 1.5 \times d}{2} = d\sqrt{1.5^2 + 1} = \sqrt{3.25}\, d = 1.8\, d$ or $\frac{b + 3d}{2} = 1.8\, d$

$\therefore$ $b = 2 \times 1.8 - 3d = 0.6\, d$ ...(*i*)

But area of trapezoidal section, $A = (b + nd)d = (0.6d + 1.5d)d$ ($\because$ $b = 0.6d$, $n = 1.5$)

$= 2.1\, d^2$

Also area, $A = \frac{\text{Discharge}}{\text{Velocity}} = \frac{Q}{V} = \frac{10.0}{1.5} = 6.67\ m^2$

Equating the two values of A, we have $2.1\, d^2 = 6.67$

$\therefore$ $d = \sqrt{\frac{6.67}{2.1}} = 1.78$ m

From equation (*i*), $b = 0.6d = 0.6 \times 1.78 = 1.068 \simeq 1.07$ m

Hence wetted perimeter, $P = b + 2d\sqrt{n^2 + 1} = 1.07 + 2 \times 1.78\sqrt{1.5^2 + 1}$ = **7.48 m. Ans.**

(*ii*) Slope of the bed when $N = 0.014$ in the formula, $C = \frac{1}{N} m^{1/6}$

For the most economical trapezoidal section, hydraulic mean depth m, is given by equation (16.12) as

$$m = \frac{d}{2} = \frac{1.78}{2} = 0.89 \text{ m}$$

$$C = \frac{1}{0.014} \times (.89)^{1/6} = 66.09$$

Using equation (16.5), $Q = AC\sqrt{mi}$

or $$10.0 = 6.67 \times 66.09\sqrt{0.89} \times i = 415.86\sqrt{i}$$

$\therefore$ $$i = \left(\frac{10}{415.86}\right)^2 = \mathbf{\frac{1}{1729.4}}. \quad \textbf{Ans.}$$

Hence slope of the bed is 1 in 1729.4.

16.5.3 Best Side Slope for Most Economical Trapezoidal Section.

Area of trapezoidal section, $A = (b + nd)d$ ...(*i*)

where b = width of trapezoidal channel, d = depth of flow, and

n = slope of the side of the channel

From equation (*i*), $b = \frac{A}{d} - nd$ ...(*ii*)

Perimeter (wetted) of channel, $P = b + 2d\sqrt{n^2 + 1}$

Substituting the value of b from equation (*ii*), perimeter becomes

$$P = \frac{A}{d} - nd + 2d\sqrt{n^2 + 1} \quad ...(iii)$$

For the most economical trapezoidal section, the depth of flow, d and area A are constant. Then n is the only variable. Best side slope will be when section is most economical or in other words, P is minimum. For P to be minimum, we must have $\frac{dP}{dn} = 0$

Hence differentiating equation (*iii*) with respect to n,

$$\frac{d}{dn}\left[\frac{A}{d} - nd + 2d\sqrt{n^2 + 1}\right] = 0$$

or $$-d + 2d \times \frac{1}{2} \times (n^2 + 1)^{1/2-1} \times 2n = 0 \text{ or } -d + 2nd \times \frac{1}{\sqrt{n^2 + 1}} = 0$$

Cancelling d and re-arranging, we get $2n = \sqrt{n^2 + 1}$

Squaring to both sides,

$$4n^2 = n^2 + 1 \text{ or } 3n^2 = 1 \text{ or } n = \sqrt{\frac{1}{3}} = \frac{1}{\sqrt{3}} \quad ...(16.14)$$

If the sloping side makes an angle θ, with the horizontal, then we have

$$\tan\theta = \frac{1}{n} = \frac{1}{\frac{1}{\sqrt{3}}} = \sqrt{3} = \tan 60°$$

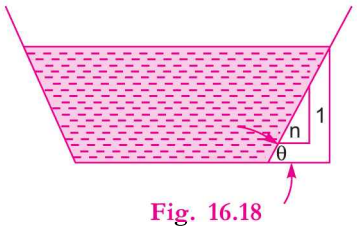

Fig. 16.18

$$\therefore \qquad \theta = 60° \qquad \ldots(16.15)$$

Hence best side slope is at 60° to the horizontal or the value of n for the best side slope is given by equation (16.14).

For the most economical trapezoidal section, we have

Half of top width = length of one sloping side

or
$$\frac{b + 2nd}{2} = d\sqrt{n^2 + 1}$$

Substituting the value of n from equation (16.14), we have

$$\frac{b + 2 \times \frac{1}{\sqrt{3}} \times d}{2} = d\sqrt{\left(\frac{1}{\sqrt{3}}\right)^2 + 1} = \frac{2d}{\sqrt{3}} \quad \text{or} \quad \frac{\sqrt{3}b + 2d}{2 \times \sqrt{3}} = \frac{2d}{\sqrt{3}}$$

or
$$\sqrt{3}b + 2d = 2 \times \sqrt{3} \times \frac{2d}{\sqrt{3}} = 4d$$

$$\therefore \qquad b = \frac{4d - 2d}{\sqrt{3}} = \frac{2d}{\sqrt{3}} \qquad \ldots(iv)$$

Now, wetted perimeter, $P = b + 2d\sqrt{n^2 + 1}$

$$= \frac{2d}{\sqrt{3}} + 2d\sqrt{\left(\frac{1}{\sqrt{3}}\right)^2 + 1} \qquad \left(\because\ b = \frac{2d}{\sqrt{3}}, n = \frac{1}{\sqrt{3}}\right)$$

$$= \frac{2d}{\sqrt{3}} + 2d \times \frac{2}{\sqrt{3}} = \frac{2d}{\sqrt{3}} + \frac{4d}{\sqrt{3}}$$

or
$$P = \frac{6d}{\sqrt{3}} = 3 \times \frac{2d}{\sqrt{3}} = 3 \times b \qquad \left(\because\ \text{From } (iv), \frac{2d}{\sqrt{3}} = b\right)$$

For a slope of 60°, the length of sloping side is equal to the width of the trapezoidal section.

Problem 16.23 *A power canal of trapezoidal section has to be excavated through hard clay at the least cost. Determine the dimensions of the channel given, discharge equal to 14 m^3/s, bed slope 1 : 2500 and Manning's N = 0.020.*

Solution. Given :

Discharge, $Q = 14\ m^3/s$

Bed slope, $i = \frac{1}{2500}$

Manning's, $N = 0.020$

For excavation of the canal at the least cost, the trapezoidal section should be most economical. Here side slope (*i.e.*, value of n) is not given. Hence the best side slope for most economical trapezoidal section (*i.e.*, the value of n) is given by equation (16.14) as $n = \frac{1}{\sqrt{3}}$

Let b = width of channel, d = depth of flow

For most economical section,

Half of top width = length of one of sloping side

or $$\frac{b + 2nd}{2} = d\sqrt{n^2 + 1}$$

For $n = \frac{1}{\sqrt{3}}$, $$\frac{b + 2 \times \frac{1}{\sqrt{3}} d}{2} = d\sqrt{\left(\frac{1}{\sqrt{3}}\right)^2 + 1} = \frac{2d}{\sqrt{3}}$$

or $$b = \frac{2 \times 2d}{\sqrt{3}} - \frac{2d}{\sqrt{3}} = \frac{2d}{\sqrt{3}} \qquad ...(i)$$

Area of trapezoidal section, $A = (b + nd) \times d = \left(\frac{2d}{\sqrt{3}} + \frac{1}{\sqrt{3}} d\right) \times d \qquad \left(\because\ b = \frac{2d}{\sqrt{3}}, n = \frac{1}{\sqrt{3}}\right)$

$$= \sqrt{3} d^2$$

Hydraulic mean depth for most economical section, $m = \frac{d}{2}$

Now discharge, Q is given by $Q = AC\sqrt{mi}$, where $C = \frac{1}{N} m^{1/6}$

$\therefore$ $$Q = \sqrt{3} d^2 \times \frac{1}{N} m^{1/6} \sqrt{m \times \frac{1}{2500}}$$

$$= \sqrt{3} d^2 \times \frac{1}{0.020} \times m^{1/6 + 1/2} \times \sqrt{\frac{1}{2500}} = 1.732\ d^2 \times m^{2/3}$$

or $$14.0 = 1.732\ d^2 \times \left(\frac{d}{2}\right)^{2/3} = \frac{1.732}{2^{2/3}} d^{8/3} = 1.09\ d^{8/3}$$

$\therefore$ $$d^{8/3} = \frac{14.0}{1.09} = 12.844$$

$\therefore$ $$d = (12.844)^{3/8} = (12.844)^{0.375} = \mathbf{2.605\ m.\ Ans.}$$

From equation (*i*), $$b = \frac{2d}{\sqrt{3}} = \frac{2 \times 2.605}{1.732} = \mathbf{3.008\ m.\ Ans.}$$

Problem 16.24 *For a trapezoidal channel with bottom width 40 m and side slopes 2H : 1 V, Manning's N is 0.015 and bottom slope is 0.0002. If it carries 60 m^3/s discharge, determine the normal depth.*

Solution. Given :

Bottom width, $b = 40$ m

Side slopes 2 horizontal to 1 vertical *i.e.*, $n = 2$

$\therefore$ Manning's constant, $N = 0.015$

Bed slope, $i = 0.0002$

Discharge, $Q = 60$ m^3/s

Let d = Normal depth.

Now $A = (b + nd) \times d = (40 + 2d) \times d$

$$P = b + 2d\sqrt{1 + n^2} = 40 + 2d\sqrt{1 + 2^2} = 40 + 2 \times \sqrt{5}\, d = 40 + 4.472\, d$$

$\therefore$ $$m = \frac{A}{P} = \frac{(40 + 2d) \times d}{40 + 4.472d}$$

The discharge is given by, Q = Area × Velocity

$$= A \times \frac{1}{N} m^{2/3}\, i^{1/2} = \frac{A}{N} \times m^{2/3} \times i^{1/2}$$

$$60 = \frac{(40 + 2d) \times d}{0.015} \times \left[\frac{(40 + 2d) \times d}{40 + 4.472d}\right]^{2/3} \times 0.0002^{1/2}$$

$$= \frac{[(40 + 2d) \times d]^{5/3}}{0.015 \times (40 + 4.472d)^{2/3}} \times 0.01414$$

$\therefore$ $$\frac{60 \times 0.015 \times (40 + 4.472d)^{2/3}}{0.01414} = [(40 + 2d) \times d]^{5/3}$$

$$63.65(40 + 4.472\, d)^{2/3} = (40d + 2d^2)^{5/3}$$

$$(40d + 2d^2)^{5/3} - 63.65\,(40 + 4.472d)^{2/3} = 0 \qquad ...(i)$$

The above equation will be solved by Hit and Trial method.

(*i*) Assume $d = 1$ m, then L.H.S of equation (*i*) will as

$$\text{L.H.S.} = (40 + 2)^{5/3} - 63.65\,(40 + 4.472)^{2/3}$$
$$= 42^{5/3} - 63.65 \times 44.472^{2/3} = 513.838 - 808.4 = -294.56$$

(*ii*) Assume $d = 2$ m, then L.H.S. of equation (*i*) will be as

$$\text{L.H.S.} = (40 \times 2 + 2 \times 2^2)^{5/3} - 63.65(40 + 4.47 \times 2)^{2/3}$$
$$= 88^{5/3} - 63.65 \times 48.944^{2/3} = 1767.2 - 862.77 = 904.43$$

where $d = 1$ m, L.H.S. is – ve. But when $d = 2$ m, L.H.S. is +ve. Hence value of d lies between 1 and 2.

(*iii*) Assume $d = 1.3$ m, then L.H.S. of equation (*i*) will be as

$$\text{L.H.S.} = (40 \times 1.3 + 2 \times 1.3^2)^{5/3} - 63.65(40 + 4.472 \times 1.3)^{2/3}$$
$$= 55.38^{5/3} - 63.65 \times 45.8136^{2/3} = 815.45 - 825.4 = -9.95$$

(*iv*) Assume $d = 1.31$ m, then L.H.S. of equation (*i*) will be

$$\text{L.H.S.} = (40 \times 1.31 + 2 \times 1.31^2)^{5/3} - 63.65(40 + 4.472 \times 1.31)^{2/3}$$
$$= 55.8322^{5/3} - 63.65 \times 45.8583^{2/3} = 826.6 - 825.9 = 0.7$$

The value of L.H.S. = 0.7 is negligible in comparison to the value of 904.43.

$\therefore$ Value of d = **1.31 m. Ans.**

16.5.4 Flow Through Circular Channel. The flow of a liquid through a circular pipe, when the level of liquid in the pipe is below the top of the pipe is classified as an open channel flow. The rate of flow through circular channel is determined from the depth of flow and angle subtended by the liquid surface at the centre of the circular channel.

Fig.16.19 shows a circular channel through which water is flowing.

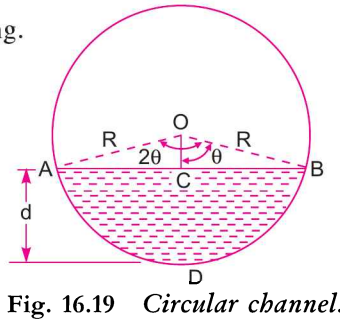

Fig. 16.19 *Circular channel.*

Let d = depth of water,

2θ = angle subtended by water surface AB at the centre in radians,

R = radius of the channel,

Then the wetted perimeter and wetted area is determine as :

Wetted perimeter, $P = \dfrac{2\pi R}{2\pi} \times 2\theta = 2R\theta$ ...(16.16)

Wetted area, A = Area $ADBA$

= Area of sector $OADBO$ – Area of ΔABO

$$= \frac{\pi R^2}{2\pi} \times 2\theta - \frac{AB \times CO}{2} = R^2\theta - \frac{2BC \times CO}{2} \qquad (\because \ AB = 2BC)$$

$$= R^2\theta - \frac{2 \times R \sin\theta \times R \cos\theta}{2} \qquad (\because \ BC = R \sin\theta, \ CO = R \cos\theta)$$

$$= R^2\theta - \frac{R^2 \times 2 \sin\theta \cos\theta}{2} = R^2\theta - \frac{R^2 \sin 2\theta}{2} \qquad (\because \ 2 \sin\theta \cos\theta = \sin 2\theta)$$

$$= R^2\left(\theta - \frac{\sin 2\theta}{2}\right) \qquad ...(16.17)$$

Then hydraulic mean depth, $m = \dfrac{A}{P} = \dfrac{R^2\left(\theta - \dfrac{\sin 2\theta}{2}\right)}{2R\theta} = \dfrac{R}{2\theta}\left(\theta - \dfrac{\sin 2\theta}{2}\right)$

And discharge, Q is given by, $Q = AC\sqrt{mi}$.

Problem 16.25 *Find the discharge through a circular pipe of diameter 3.0 m, if the depth of water in the pipe is 1.0 m and the pipe is laid at a slope of 1 in 1000. Take the value of Chezy's constant as 70.*

Solution. Given :

Dia. of pipe, $D = 3.0$

$\therefore$ Radius, $R = \dfrac{D}{2} = \dfrac{3.0}{2} = 1.50$ m

Depth of water in pipe, $d = 1.0$ m

Bed slope, $i = \dfrac{1}{1000}$

Chezy's constant, $C = 70$

From Fig. 16.20, we have $OC = OD - CD = R - 1.0$

$= 1.5 - 1.0 = 0.5$ m

$AO = R = 1.5$ m

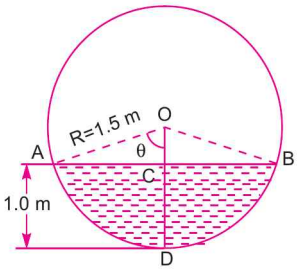

Fig. 16.20

Also $\cos\theta = \frac{OC}{AO} = \frac{0.5}{1.5} = \frac{1}{3}$

$\therefore$ $\theta = 70.53° = 70.53 \times \frac{\pi}{180} = 1.23$ radians ($\because$ 180° = π radians)

Wetted perimeter is given by equation (16.16) as

$P = 2R\theta = 2 \times 1.5 \times 1.23$ (θ should be in radians)

$= 3.69$ m

Wetted area is given by equation (16.17) as

$$A = R^2\left(\theta - \frac{\sin 2\theta}{2}\right) = 1.5^2\left(1.23 - \frac{\sin(2 \times 70.53°)}{2}\right)$$

$$= 2.25\left[1.23 - \frac{\sin(141.08°)}{2}\right] = 2.25\left[1.23 - \frac{\sin(180° - 141.08°)}{2}\right]$$

$$= 2.25\left[1.23 - \frac{\sin 38.94°}{2}\right] = 2.06 \text{ m}^2$$

$\therefore$ Hydraulic mean depth, $m = \frac{A}{P} = \frac{2.06}{3.69} = .5582$

The discharge is given by, $Q = AC\sqrt{mi} = 2.06 \times 70 \times \sqrt{0.5582 \times \frac{1}{1000}}$ = **3.407 m²/s. Ans.**

Problem 16.26 *If in the problem 16.25, the depth of water in the pipe is 2.5 m, find the rate of flow through the pipe.*

Solution. Given :

Dia. of pipe = 3.0 m

$\therefore$ Radius, $R = 1.5$ m

Depth of water, $d = 2.5$ m

$i = \frac{1}{1000}$ and $C = 70$

From Fig. 16.21, $OC = CD - OD = 2.5 - R = 2.5 - 1.5 = 1.0$ m

$OA = R = 1.5$ m

From ΔAOC, $\cos\alpha = \frac{OC}{OA} = \frac{1.0}{1.5} = 0.667$

$\therefore$ $\alpha = 48.16°$

$\theta = 180° - \alpha = 180° - 48.16° = 131.84°$

$= 131.84 \times \frac{\pi}{180} = 2.30$ radians

Now wetted perimeter is given by equation (16.16) as

$P = 2R\theta = 2 \times 1.5 \times 2.30 = 6.90$ m

And wetted area is given by equation (16.17) as

$$A = R^2\left(\theta - \frac{\sin 2\theta}{2}\right) = 1.5^2\left(2.30 - \frac{\sin(2\times 131.84°)}{2}\right)$$

$$= 2.25\left(2.30 - \frac{\sin 263.68°}{2}\right)$$

$$= 2.25\left[2.30 - \frac{\sin(180° + 83.68°)}{2}\right]$$

$$= 2.25\left[2.30 - \frac{(-\sin 83.58°)}{2}\right]$$

$$= 2.25\left[2.30 + \frac{\sin 83.68°}{2}\right] = 6.293 \text{ m}^2$$

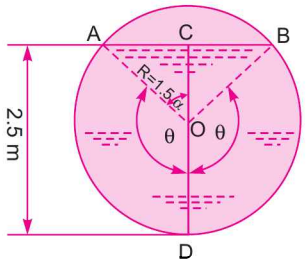

Fig. 16.21

$\therefore$ Hydraulic mean depth, $m = \frac{A}{P} = \frac{6.293}{6.90} = 0.912$ m

Discharge, Q is given by, $Q = AC\sqrt{mi} = 6.293 \times 70 \times \sqrt{0.912 \times \frac{1}{1000}}$ = **13.303 m^3/s. Ans.**

Problem 16.27 *Calculate the quantity of water that will be discharged at a uniform depth of 0.9 m in a 1.2 m diameter pipe which is laid at a slope 1 in 1000. Assume Chezy's C = 58.*

Solution. Given :

Dia. of pipe = 1.2 m

$\therefore$ Radius, $R = \frac{1.2}{2} = 0.6$ m

Depth of water, $d = 0.9$ m

Slope, $i = \frac{1}{1000}$

Chezy's, $C = 58$

From Fig. 16.22, we have $OC = CD - OD$

$= 0.9 - R = 0.9 - 0.6 = 0.3$ m

$OA = R = 0.6$ m

Now in triangle AOC,

$$\cos\alpha = \frac{OC}{OA} = \frac{0.3}{0.6} = \frac{1}{2}$$

$\therefore$ $\alpha = \cos^{-1}\left(\frac{1}{2}\right) = 60°$

$\therefore$ θ = Angle $DOA = 180° - \alpha$

$= 180° - 60° = 120° = 120 \times \frac{\pi}{180}$ radians

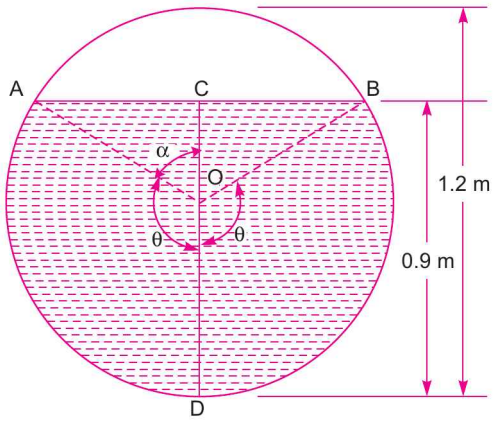

Fig. 16.22

$= 0.667\ \pi$ radians

Now wetted perimeter is given by equation (16.16) as

$$P = 2R\theta = 2 \times 0.6 \times 0.667\ \pi = 2.526 \text{ m}$$

And area of flow is given by equation (16.17) as

$$A = R^2\left(\theta - \frac{\sin 2\theta}{2}\right)$$

$$= 0.6^2\left[0.667\pi - \frac{\sin(2\times 120°)}{2}\right] = 0.36\left[0.667\pi - \frac{\sin 240°}{2}\right]$$

$$= 0.36\left[0.667\pi - \frac{(-0.866)}{2}\right] = 0.36\ [0.667\ \pi + 0.433] = 0.913 \text{ m}^2$$

Now discharge is given by, $Q = A \times V = A \times C\sqrt{mi} = 0.913 \times 58\sqrt{\frac{A}{P} \times \frac{1}{1000}}$ $\left(\because\ m = \frac{A}{P}\right)$

$$= 0.913 \times 58\sqrt{\frac{0.913}{2.526} \times \frac{1}{1000}} = \mathbf{1.007\ m^3/s.\ Ans.}$$

Problem 16.28 *Water is flowing through a circular channel at the rate of 400 litres/s, when the channel is having a bed slope of 1 in 9000. The depth of water in the channel is 8.0 times the diameter. Find the diameter of the circular channel if the value of Manning's N = 0.015.*

Solution. Given :

Discharge, $Q = 400$ litres/s $= 0.4$ m^3/s

Bed slope, $i = \frac{1}{9000}$

Manning's, $N = 0.015$

Let the diameter of channel $= D$

Then depth of flow, $d = 0.8\ D$

From Fig. 16.23, we have

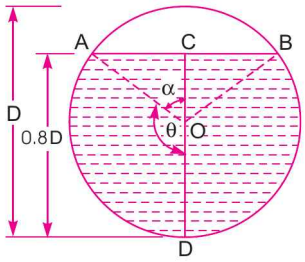

Fig. 16.23

$$OC = CD - OD = 0.8\ D - \frac{D}{2}$$

$$= (0.8 - 0.5)\ D = 0.3\ D$$

And $AO = R = \frac{D}{2} = 0.5\ D$

$\therefore$ $\cos\alpha = \frac{OC}{AO} = \frac{0.3\ D}{0.5\ D} = 0.6$

$\therefore$ $\alpha = 53.13°$

And $\theta = 180° - 53.13 = 126.87° = 126.87 \times \frac{\pi}{180} = 2.214$ radians.

From equation (16.16), wetted perimeter,

$$P = 2R\theta = 2 \times \frac{D}{2} \times 2.214 = 2.214\ D \text{ m.}$$

From equation (16.17), wetted area,

$$A = R^2\left(\theta - \frac{\sin 2\theta}{2}\right) = \left(\frac{D}{2}\right)^2 \left[2.214 - \frac{\sin (2 \times 126.87°)}{2}\right]$$

$$= \frac{D^2}{4}\left[2.214 - \frac{\sin 253.74°}{2}\right] = \frac{D^2}{4}\left[2.214 - \frac{\sin (180° + 73.74°)}{2}\right]$$

$$= \frac{D^2}{4}\left[2.214 - \left(\frac{-\sin 73.74°}{2}\right)\right] = \frac{D^2}{4}\left[2.214 + \frac{\sin 73.74°}{2}\right]$$

$$= \frac{D^2}{4}\ [2.214 + .48] = 0.6735\ D^2$$

$\therefore$ Hydraulic mean depth, $m = \dfrac{A}{P} = \dfrac{0.6735\ D^2}{2.214\ D} = 0.3042\ D$

Discharge by Manning's formula is given by,

$$Q = \frac{1}{N} \times A \times m^{2/3} \times i^{1/2}$$

or
$$0.4 = \frac{1}{.015} \times 0.6735\ D^2 \times (.3042\ D)^{2/3} \times \left(\frac{1}{9000}\right)^{1/2}$$

$$= \frac{0.6735}{0.015}\ D^2 \times 34521 \times D^{2/3} \times 0.0105 = 0.213\ D^{8/3}$$

$\therefore$
$$D^{8/3} = \frac{0.40}{0.213} = 1.8779$$

$\therefore$
$$D = (1.8779)^{3/8} = (1.8779)^{0.375} = \textbf{1.266 m. Ans.}$$

Problem 16.29 *A sewer pipe is to be laid at a slope of 1 in 8100 to carry a maximum discharge of 600 litres/s, when the depth of water is 75% of the vertical diameter. Find the diameter of this pipe if the value of Manning's N is 0.025.*

Solution. Given :

Discharge, $Q = 600$ litres/s $= 0.6$ m^3/s

Bed slope, $i = \dfrac{1}{8100}$

Manning's, $N = 0.025$

Depth of water = 75% of dia. of pipe = 0.75 dia. of pipe

Let d = depth of water, D = Dia. of pipe

Then $d = 0.75\ D$

From Fig. 16.23 (*a*), we have $OC = CD - OD = 0.75\ D - 0.5\ D = 0.25\ D$

$$AO = R = 0.5\ D$$

In triangle AOC, $$\cos\ \alpha = \frac{OC}{AO} = \frac{0.25\ D}{0.5\ D} = 0.5$$

$$\therefore \quad \alpha = \cos^{-1} 0.5 = 60°$$

And $$\theta = 180° - \alpha = 180° - 60° = 120°$$

$$= 120 \times \frac{\pi}{180} \text{ radians} = 2.0946 \text{ radians.}$$

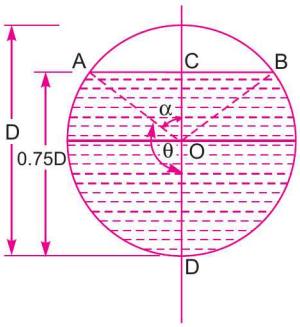

Fig. 16.23 (*a*)

From equation (16.16), wetted perimeter

$$P = 2R\theta = 2 \times 0.5\ D \times 2.0496 \quad (\because \ R = 0.5\ D)$$

$$= 2.0496\ D$$

And from equation (16.17), the area of flow,

$$A = R^2\left(\theta - \frac{\sin 2\theta}{2}\right)$$

$$= (0.5\ D)^2 \left[2.0946 - \frac{\sin\ (2 \times 120°)}{2}\right]$$

$$= 0.25\ D^2 \left[2.0946 - \left(\frac{-.866}{2}\right)\right] = 0.25\ D^2\ [2.0946 + 0.433]$$

$$= 0.6319\ D^2$$

$$\therefore \quad m = \frac{A}{P} = \frac{0.6319\ D^2}{2.0496\ D} = 0.308\ D$$

Discharge by Manning's formula is given by

$$Q = \frac{1}{N} \times A \times m^{2/3} \times i^{1/2}$$

or $$0.6 = \frac{1}{0.025} \times 0.6319\ D^2 \times (0.308\ D)^{2/3} \times \left(\frac{1}{8100}\right)^{1/2} = 0.128 \times D^{8/3}$$

$$\therefore \quad D^{8/3} = \frac{0.6}{0.128} = 4.6875$$

$$\therefore \quad D = (4.6875)^{3/8} = \mathbf{1.785\ m.\ Ans.}$$

16.5.5 Most Economical Circular Section. We have discussed in Art. 16.5 that for a most economical section the discharge for a constant cross-sectional area, slope of bed and resistance co-efficient, is maximum. But in case of circular channels, the area of flow cannot be maintained constant. With the change of depth of flow in a circular channel of any radius, the wetted area and wetted perimeter changes. Thus in case of circular channels, for most economical section, two separate conditions are obtained. They are :

1. Condition for maximum velocity, and
2. Condition for maximum discharge.

1. Condition for Maximum Velocity for Circular Section. Fig. 16.24 shows a circular channel through which water is flowing.

Let d = depth of water,
2θ = angle subtended at the centre by water surface,
R = radius of channel, and
i = slope of the bed,

The velocity of flow according to Chezy's formula is given as

$$V = C\sqrt{mi} = C\sqrt{\frac{A}{P}\,i} \quad \left(\because \quad m = \frac{A}{P}\right)$$

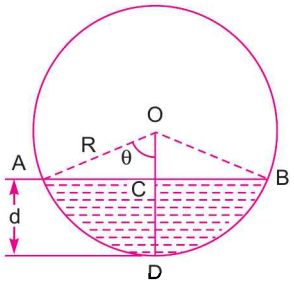

Fig. 16.24

The velocity of flow through a circular channel will be maximum when the hydraulic mean depth m or A/P is maximum for a given value of C and i. In case of circular pipe, the variable is θ only. Hence for maximum value of A/P we have the condition,

$$\frac{d\left(\frac{A}{P}\right)}{d\theta} = 0 \qquad \ldots(i)$$

where A and P both are functions of θ.

The value of wetted area, A is given by equation (16.17) as

$$A = R^2\left(\theta - \frac{\sin 2\theta}{2}\right) \qquad \ldots(ii)$$

The value of wetted perimeter, P is given by equation (16.16) as

$$P = 2R\theta \qquad \ldots(iii)$$

Differentiating equation (i) with respect to θ, we have

$$\frac{P\frac{dA}{d\theta} - A\frac{dP}{d\theta}}{P^2} = 0 \quad \text{or} \quad P\frac{dA}{d\theta} - A\frac{dP}{d\theta} = 0 \qquad \ldots(iv)$$

From equation (ii), $\quad \dfrac{dA}{d\theta} = R^2\left(1 - \dfrac{\cos 2\theta}{2} \times 2\right) = R^2(1 - \cos 2\theta)$

From equation (iii), $\quad \dfrac{dP}{d\theta} = 2R$

Substituting the values of A, $P\dfrac{dA}{d\theta}$ and $\dfrac{dP}{d\theta}$ in equation (iv),

$$2R\theta\left[R^2(1 - \cos 2\theta)\right] - R^2\left(\theta - \frac{\sin 2\theta}{2}\right)(2R) = 0$$

or $$2R^3\theta(1 - \cos 2\theta) - 2R^3\left(\theta - \frac{\sin 2\theta}{2}\right) = 0$$

or $$\theta(1 - \cos 2\theta) - \left(\theta - \frac{\sin 2\theta}{2}\right) = 0 \qquad \text{(Cancelling } 2R^3\text{)}$$

$$\theta - \theta \cos 2\theta - \theta + \frac{\sin 2\theta}{2} = 0$$

or $$\theta \cos 2\theta = \frac{\sin 2\theta}{2} \quad \text{or} \quad \frac{\sin 2\theta}{\cos 2\theta} = 2\theta$$

$\therefore$ $$\tan 2\theta = 2\theta$$

The solution of this equation by hit and trial, gives

$$2\theta = 257^\circ\ 30' \qquad \text{(approximately)}$$

or $$\theta = 128^\circ\ 45'$$

The depth of flow for maximum velocity from Fig. 16.24, is

$$d = OD - OC = R - R\cos\theta$$
$$= R[1 - \cos\theta] = R[1 - \cos 128^\circ\ 45'] = R[1 - \cos(180^\circ - 51^\circ\ 15')]$$
$$= R[1 - (-\cos 51^\circ\ 15')] = R[1 + \cos 51^\circ\ 15']$$
$$= R[1 + 0.62] = 1.62\ R = 1.62 \times \frac{D}{2} = 0.81\ D \qquad ...(16.18)$$

where D = diameter of the circular channel.

Thus for maximum velocity of flow, the depth of water in the circular channel should be equal to 0.81 times the diameter of the channel.

Hydraulic mean depth for maximum velocity is

$$m = \frac{A}{P} = \frac{R^2\left(\theta - \frac{\sin 2\theta}{2}\right)}{2R\theta} = \frac{R}{2\theta}\left[\theta - \frac{\sin 2\theta}{2}\right]$$

where $\theta = 128^\circ\ 45' = 128.75^\circ$

$$= 128.75 \times \frac{\pi}{180} = 2.247 \text{ radians}$$

$\therefore$ $$m = \frac{R}{2 \times 2.247}\left[2.247 - \frac{\sin 257^\circ\ 30'}{2}\right] = \frac{R}{4.494}\left[2.247 - \frac{\sin(180^\circ + 87.5^\circ)}{2}\right]$$

$$= \frac{R}{4.494}\left[2.247 + \frac{\sin 87.5^\circ}{2}\right] = 0.611\ R$$

$$= 0.611 \times \frac{D}{2} = 0.3055\ D = 0.3\ D \qquad ...(16.19)$$

Thus for maximum velocity, the hydraulic mean depth is equal to 0.3 times the diameter of circular channel.

2. Condition for Maximum Discharge for Circular Section. The discharge through a channel is given by

$$Q = AC\sqrt{mi} = AC\sqrt{\frac{A}{P}i} \qquad \left(\because\ m = \frac{A}{P}\right)$$

$$= C\sqrt{\frac{A^3}{P}i}$$

The discharge will be maximum for constant values of C and i, when $\frac{A^3}{P}$ is maximum. $\frac{A^3}{P}$ will be maximum when $\frac{d}{d\theta}\left(\frac{A^3}{P}\right) = 0$.

Differentiating this equation with respect to θ and equation the same to zero, we get

$$\frac{P \times 3A^2 \frac{dA}{d\theta} - A^3 \frac{dP}{d\theta}}{P^2} = 0 \quad \text{or} \quad 3PA^2 \frac{dA}{d\theta} - A^3 \frac{dP}{d\theta} = 0$$

Dividing by A^2, $3P \frac{dA}{d\theta} - A \frac{dP}{d\theta} = 0$ ...(*i*)

But from equation (16.16), $P = 2R\theta$

$$\therefore \quad \frac{dP}{d\theta} = 2R$$

From equation (16.17), $A = R^2\left(\theta - \frac{\sin 2\theta}{2}\right)$

$$\therefore \quad \frac{dA}{d\theta} = R^2 (1 - \cos 2\theta)$$

Substituting the values of P, A, $\frac{dP}{d\theta}$ and $\frac{dA}{d\theta}$ in equation (*i*)

$$3 \times 2R\theta \times R^2 (1 - \cos 2\theta) - R^2\left(\theta - \frac{\sin 2\theta}{2}\right) \times 2R = 0$$

$$6R^3\theta (1 - \cos 2\theta) - 2R^3\left(\theta - \frac{\sin 2\theta}{2}\right) = 0$$

Dividing by $2R^3$, we get

$$3\theta (1 - \cos 2\theta) - \left(\theta - \frac{\sin 2\theta}{2}\right) = 0 \quad \text{or} \quad 3\theta - 3\theta \cos 2\theta - \theta + \frac{\sin 2\theta}{2} = 0$$

or $$2\theta - 3\theta \cos 2\theta + \frac{\sin 2\theta}{2} = 0 \quad \text{or} \quad 4\theta - 6\theta \cos 2\theta + \sin 2\theta = 0$$

The solution of this equation by hit and trial, gives

$$2\theta = 308° \qquad \text{(approximately)}$$

$$\therefore \quad \theta = \frac{308°}{2} = 154°$$

Depth of flow for maximum discharge [See Fig. 16.24]

$$d = OD - OC = R - R \cos \theta$$
$$= R[1 - \cos \theta] = R[1 - \cos 154°]$$
$$= R[1 - \cos (180° - 26°)] = R[1 + \cos 26°] = 1.898\, R$$
$$= 1.898 \times \frac{D}{2} = 0.948\, D \simeq 0.95\, D \qquad ...(16.20)$$

where D = Diameter of the circular channel.

Thus for maximum discharge through a circular channel the depth of flow is equal to 0.95 times its diameter.

Problem 16.30 *The rate of flow of water through a circular channel of diameter 0.6 m is 150 litres/s. Find the slope of the bed of the channel for maximum velocity. Take C = 60*

Solution. Given :

Discharge, $Q = 150$ litres/s $= 0.15$ m^3/s

Dia. of channel, $D = 0.6$ m

Value of $C = 60$

Let the slope of the bed of channel for maximum velocity $= i$

For maximum velocity through a circular channel, depth of flow is given by equation (16.18) as

$$d = 0.81 \times D = 0.81 \times 0.6 = .486 \text{ m}$$

and $$\theta = 128° 45' \quad \text{or} \quad 128.75 \times \frac{\pi}{180} = 2.247 \text{ radians}$$

From equation (16.19), hydraulic mean depth for maximum velocity is given as

$$m = 0.3 \times D = 0.3 \times 0.6 = 0.18 \text{ m}$$

Wetted perimeter for circular pipe is given by equation (16.16),

$$P = 2R\theta = D \times \theta = 0.6 \times 2.247 = 1.3482 \text{ m}$$

But $$m = \frac{A}{P} = 0.18 \text{ m}$$

$\therefore$ Area, $$A = 0.18 \times P = 0.18 \times 1.3482 = 0.2426 \text{ m}^2$$

For discharge, using the relation

$$Q = AC\sqrt{mi} \quad \text{or} \quad 0.15 = 0.2426 \times 60 \times \sqrt{0.81 \times i} = 6.175\sqrt{i}$$

$\therefore$ $$i = \left(\frac{0.15}{6.175}\right)^2 = \frac{\mathbf{1}}{\mathbf{1694.7}} \textbf{ . Ans.}$$

$\therefore$ Bed slope is 1 in 1694.7.

Problem 16.31 *Determine the maximum discharge of water through a circular channel of diameter 1.5 m when the bed slope of the channel is 1 in 1000. Take C = 60.*

Solution. Given :

Dia. of channel, $D = 1.5$ m

$\therefore$ $$R = \frac{1.5}{2} = 0.75 \text{ m}$$

Bed slope, $$i = \frac{1}{1000}$$

Value of $C = 60$

For maximum discharge, $$\theta = 154° \text{ or } \frac{154 \times \pi}{180} = 2.6878 \text{ radians.}$$

Wetted perimeter for a circular channel is given by equation (16.16) as

$$P = 2R\theta = 2 \times \frac{D}{2} \times 2.6878 = 2 \times \frac{1.5}{2} \times 2.6878 = 4.0317 \text{ m}$$

Wetted area A is given by equation (16.17) as

$$A = R^2\left(\theta - \frac{\sin 2\theta}{2}\right) = 0.75^2\left[2.6878 - \frac{\sin (2 \times 154)°}{2}\right]$$

$$= 0.75^2\left[2.6878 - \frac{\sin 308°}{2}\right] = .75^2\left[2.6878 - \frac{\sin (360° - 52°)}{2}\right]$$

$$= 0.75^2\left[2.6878 + \frac{\sin 52°}{2}\right] = 1.7335$$

$\therefore$ Hydraulic mean depth, $m = \frac{A}{P} = \frac{1.7335}{4.0317} = 0.4299$

Maximum discharge is given by $Q = AC\sqrt{mi} = 1.7335 \times 60 \times \sqrt{0.4299 \times \frac{1}{1000}}$

$= \mathbf{2.1565\ m^3/s.\ Ans.}$

Problem 16.32 *A concrete lined circular channel of diameter 3 m has a bed slope of 1 in 500. Work out the velocity and flow rate for the conditions of (i) maximum velocity and (ii) maximum discharge. Assume Chezy's C = 50.*

Solution. Given :

Dia of channel, $D = 3$ m

Bed slope, $i = \frac{1}{500}$

Value of $C = 50$

(*i*) *Velocity and discharge for maximum velocity*

For maximum velocity, $\theta = 128° 45' = 128.75°$

$= 128.75 \times \frac{\pi}{180}$ radians $= 2.247$ radians

$\therefore$ Wetted perimeter, $P = 2 \times R \times \theta$

$= 2 \times 1.5 \times 2.247 \qquad \left(\because\ R = \frac{D}{2} = \frac{3}{2} = 1.5\right)$

$= 6.741$ m

Area of flow, $A = R^2\left(\theta - \frac{\sin 2\theta}{2}\right) = 1.5^2\left[2.247 - \frac{\sin (2 \times 128.75°)}{2}\right]$

$= 2.25\ [2.247 - (-0.488)] = 6.1537\ m^2$

$\therefore$ Hydraulic mean depth $m^* = \frac{A}{P} = \frac{6.1537}{6.741} = 0.912$

Now velocity, $V = C\sqrt{m \times i} = 50 \times \sqrt{\frac{0.912 \times 1}{500}} = \mathbf{2.135\ m/s.\ Ans.}$

and discharge, $Q = A \times V = 6.1537 \times 2.135 = \mathbf{13.138\ m^3/s.}$ **Ans.**

(*ii*) *Velocity and discharge for maximum discharge*

For maximum discharge, $\theta = 154° = \frac{154 \times \pi}{180}$ radians $= 2.6878$ radians

---

* From equation (16.19), m is also equal to $0.3055\ D$.

Hence $m = 0.3055 \times 3 = 0.9165$

$$\therefore \quad A = R^2\left[\theta - \frac{\sin 2\theta}{2}\right] = 1.5^2\left[2.6878 - \frac{\sin(2\times 154)}{2}\right]$$

$$= 2.25\ [2.6878 - (-0.394)] = 6.934$$

$$P = 2R \times \theta = 2 \times 1.5 \times 2.6878 = 8.0634$$

and $$m = \frac{A}{P} = \frac{6.934}{8.0634} = 0.8599$$

Now velocity $$V = C\sqrt{mi} = 50 \times \sqrt{0.8599 \times \frac{1}{500}} = \mathbf{2.0735\ m/s.\ Ans.}$$

and discharge, $$Q = A \times V = 6.934 \times 2.0735 = \mathbf{14.377\ m^3/s.\ Ans.}$$

▶ 16.6 NON-UNIFORM FLOW THROUGH OPEN CHANNELS

We have defined uniform flow and non-uniform flow in Art. 16.2.2. A flow is said to be uniform if the velocity of flow, depth of flow, slope of the bed of the channel and area of cross-section remain constant for a given length of the channel. On the other hand, if velocity of flow, depth of flow, area of cross-section and slope of the bed of channel do not remain constant for a given length of pipe, the flow is said to be non-uniform.

Non-uniform is further divided into Rapidly Varied Flow (R.V.F.), and Gradually Varied Flow (G.V.F.) depending upon the change of depth of flow over the length of the channel. If the depth of flow changes abruptly over a small length of the channel, the flow is said as rapidly varied flow. And if the depth of flow in a channel changes gradually over a long length of channel, the flow is said to be gradually varied flow.

▶ 16.7 SPECIFIC ENERGY AND SPECIFIC ENERGY CURVE

The total energy of a flowing liquid per unit weight is given by,

Total Energy $$= z + h + \frac{V^2}{2g}$$

where z = Height of the bottom of channel above datum,
h = Depth of liquid, and V = Mean velocity of flow.

If the channel bottom is taken as the datum as shown in Fig. 16.25, then the total energy per unit weight of liquid will be,

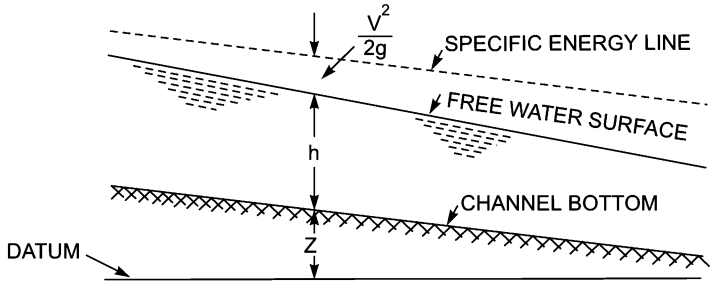

Fig. 16.25 *Specific energy.*

$$E = h + \frac{V^2}{2g} \qquad ...(16.21)$$

The energy given by equation (16.21) is known as **specific energy**. Hence specific energy of a flowing liquid is defined as energy per unit weight of the liquid with respect to the bottom of the channel.

Specific Energy Curve. It is defined as the curve which shows the variation of specific energy with depth of flow. It is obtained as :

From equation (16.21), the specific energy of a flowing liquid

$$E = h + \frac{V^2}{2g} = E_p + E_k$$

where E_p = Potential energy of flow = h

E_k = Kinetic energy of flow $= \frac{V^2}{2g}$

Consider a rectangular channel in which a steady but non-uniform flow is taking place.

Let Q = discharge through the channel,
b = width of the channel,
h = depth of flow, and
q = discharge per unit width.

Then $q = \frac{Q}{\text{width}} = \frac{Q}{b}$ = constant ($\because$ Q and b are constant)

Velocity of flow, $V = \frac{\text{Discharge}}{\text{Area}} = \frac{Q}{b \times h} = \frac{q}{h}$ $\left(\because \frac{Q}{b} = q\right)$

Substituting the values of V in equation (16.21), we get

$$E = h + \frac{q^2}{2gh^2} = E_p + E_k \qquad ...(16.22)$$

Equation (16.22), gives the variation of specific energy (E) with the depth of flow (h). Hence for a given discharge Q, for different values of depth of flow, the corresponding values of E may be obtained. Then a graph between specific energy (along X-X axis) and depth of flow, h (along Y-Y axis) may be plotted.

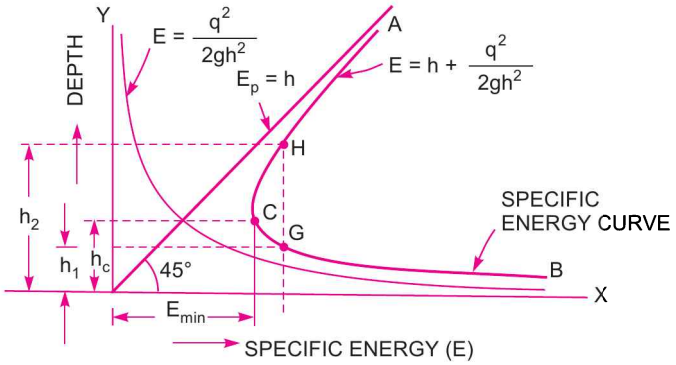

Fig. 16.26 *Specific energy curve.*

The specific energy curve may also be obtained by first drawing a curve for potential energy (*i.e.*, $E_p = h$), which will be a straight line passing through the origin, making an angle of 45° with the X - axis as shown in Fig. 16.26. Then drawing another curve for kinetic energy $\left(i.e., E_k = \frac{q^2}{2gh^2} \text{ or } E_k = \frac{K}{h^2}, \right.$ $\left. \text{where } K = \frac{q^2}{2g} = \text{constant} \right)$ which will be a parabola as shown in Fig. 16.26. By combining these two curves, we can obtain the specific energy curve. In Fig. 16.26, curve ACB denotes the specific energy curve.

16.7.1 Critical Depth (h_c). Critical depth is defined as that depth of flow of water at which the specific energy is minimum. This is denoted by 'h_c' . In Fig. 16.26, curve ACB is a specific energy curve and point C corresponds to the minimum specific energy. The depth of flow of water at C is known as critical depth. The mathematical expression for critical depth is obtained by differentiating the specific energy equation (16.22) with respect to depth of flow and equating the same to zero.

or $$\frac{dE}{dh} = 0, \qquad \text{where } E = h + \frac{q^2}{2gh^2} \text{ from equation (16.22)}$$

or $$\frac{d}{dh}\left[h + \frac{q^2}{2gh^2}\right] = 0 \quad \text{or} \quad 1 + \frac{q^2}{2g}\left(\frac{-2}{h^3}\right) = 0 \qquad \left(\because \frac{q^2}{2g} \text{ is constant}\right)$$

or $$1 - \frac{q^2}{gh^3} = 0 \quad \text{or} \quad 1 = \frac{q^2}{gh^3} \quad \text{or} \quad h^3 = \frac{q^2}{g}$$

$\therefore$ $$h = \left(\frac{q^2}{g}\right)^{1/3}$$

But when specific energy is minimum, depth is critical and it is denoted by h_c. Hence critical depth is

$$h_c = \left(\frac{q^2}{g}\right)^{1/3} \qquad ...(16.23)$$

16.7.2 Critical Velocity (V_c). The velocity of flow at the critical depth is known as critical velocity. It is denoted by V_c. The mathematical expression for critical velocity is obtained from equation (16.23) as

$$h_c = \left(\frac{q^2}{g}\right)^{1/3}$$

Taking cube to both sides, we get $h_c^3 = \frac{q^2}{g}$ or $gh_c^3 = q^2$ ...(i)

But $$q = \text{Discharge per unit width} = \frac{Q}{b}$$

$$= \frac{\text{Area} \times V}{b} = \frac{b \times h \times V}{b} = h \times V = h_c \times V_c$$

Substituting this value of q in (i),

$\therefore \quad gh_c^3 = (h_c \times V_c)^2$

or $\quad gh_c^3 = h_c^2 \times V_c^2$ or $gh_c = V_c^2$ [Dividing by h_c^2]

or $\quad V_c = \sqrt{g \times h_c}$ ...(16.24)

16.7.3 Minimum Specific Energy in Terms of Critical Depth. Specific energy equation is given by equation (16.22)

$$E = h + \frac{q^2}{2gh^2}$$

When specific energy is minimum, depth of flow is critical and hence above equation becomes as

$$E_{min} = h_c + \frac{q^2}{2gh_c^2} \qquad ...(ii)$$

But from equation (16.23), $h_c = \left(\frac{q^2}{g}\right)^{1/3}$ or $h_c^3 = \frac{q^2}{g}$

Substituting the value of $\frac{q^2}{g} = h_c^3$ in equation (ii), we get

$$E_{min} = h_c + \frac{h_c^3}{2h_c^2} = h_c + \frac{h_c}{2} = \frac{3h_c}{2}. \qquad ...(16.25)$$

Problem 16.33 *Find the specific energy of flowing water through a rectangular channel of width 5 m when the discharge is 10 m^3/s and depth of water is 3 m.*

Solution. Given :

Width of rectangular channel, $b = 5$ m

Discharge, $Q = 10$ m^3/s

Depth of water, $h = 3$ m

Specific energy is given by equation (16.21), as

$$E = h + \frac{V^2}{2g}, \quad \text{where } V = \frac{Q}{\text{Area}} = \frac{10}{b \times h} = \frac{10}{5 \times 3} = \frac{2}{3}$$

$\therefore$

$$E = 3 + \frac{\left(\frac{2}{3}\right)^2}{2 \times 9.81} = 3 + .0226 = \mathbf{3.0226\ m.\ Ans.}$$

Problem 16.34 *Find the critical depth and critical velocity of the water flowing through a rectangular channel of width 5 m, when discharge is 15 m^3/s.*

Solution. Given :

Width of channel, $b = 5$ m

Discharge, $Q = 15$ m^3/s

$\therefore$ Discharge per unit width, $q = \frac{Q}{b} = \frac{15}{5} = 3$ m^2/s

Critical depth is given by equation (16.23) as

$$h_c = \left(\frac{q^2}{g}\right)^{1/3} = \left(\frac{3^2}{9.81}\right)^{1/3} = \left(\frac{9}{9.81}\right)^{1/3} = \mathbf{0.972\ m.\ Ans.}$$

Critical velocity is given by equation (16.24) as

$$V_c = \sqrt{g \times h_c} = \sqrt{9.81 \times 0.972} = \mathbf{3.088\ m/s.\ Ans.}$$

Problem 16.35 *The discharge of water through a rectangular channel of width 8 m, is 15 m^3/s when depth of flow of water is 1.2 m. Calculate :*

(i) Specific energy of the flowing water, (ii) Critical depth and critical velocity,

(iii) Value of minimum specific energy.

Solution. Given :

Discharge, $Q = 15\ m^3/s$

Width, $b = 8\ m$

Depth, $h = 1.2\ m$

$\therefore$ Discharge per unit width, $q = \frac{Q}{b} = \frac{15}{8} = 1.875\ m^2/s$

Velocity of flow, $V = \frac{Q}{\text{Area}} = \frac{15}{b \times h} = \frac{15.0}{8 \times 1.2} = 1.5625\ m/s$

(*i*) Specific energy (E) is given by equation (16.21) as

$$E = h + \frac{V^2}{2g} = 1.2 + \frac{1.5625^2}{8 \times 9.81} = 1.20 + 0.124 = \mathbf{1.324\ m.\ Ans.}$$

(*ii*) Critical depth (h_c) is given by equation (16.23) as

$$h_c = \left(\frac{q^2}{g}\right)^{1/3} = \left(\frac{1.875^2}{9.81}\right)^{1/3} = \mathbf{0.71\ m.\ Ans.}$$

Critical velocity (V_c) is given by equation (16.24) as

$$V_c = \sqrt{g \times h_c} = \sqrt{9.81 \times 0.71} = \mathbf{2.639\ m/s.\ Ans.}$$

(*iii*) Minimum specific energy (E_{min}) is given by equation (16.25)

$$E_{min} = \frac{3h_c}{2} = \frac{3 \times 0.71}{2} = \mathbf{1.065\ m.\ Ans.}$$

16.7.4 Critical Flow. It is defined as that flow at which the specific energy is minimum or the flow corresponding to critical depth is defined as critical flow. Equation (16.24) gives the relation for critical velocity in terms of critical depth as

$$V_c = \sqrt{g \times h_c} \quad \text{or} \quad \frac{V_c}{\sqrt{g h_c}} = 1 \qquad \left| \text{where } \frac{V_c}{\sqrt{g h_c}} = \text{Froude number} \right.$$

$\therefore$ Froude number, $F_e = 1.0$ for critical flow.

16.7.5 Streaming Flow or Sub-critical Flow or Tranquil Flow. When the depth of flow in a channel is greater than the critical depth (h_c), the flow is said to be sub-critical flow or streaming flow or tranquil flow. For this type of flow the Froude number is less than one *i.e.*, $F_e < 1.0$.

16.7.6 Super-critical Flow or Shooting Flow or Torrential Flow. When the depth of flow in a channel is less than the critical depth (h_c), the flow is said to be super-critical flow or shooting flow or torrential flow. For this type of flow the Froude number is greater than one *i.e.*, $F_e > 1.0$.

16.7.7 Alternate Depths. In the specific energy curve shown in Fig. 16.26, the point C corresponds to the minimum specific energy and the depth of flow at C is called critical depth. For any other value of the specific energy, there are two depths, one greater than the critical depth and other smaller than the critical depth. These two depths for a given specific energy are called the alternate depths. These depths are shown as h_1 and h_2 in Fig. 16.26. Or the depths corresponding to points G and H in Fig. 16.26 are called alternate depths.

16.7.8 Condition for Maximum Discharge for a Given Value of Specific Energy. The specific energy (E) at any section of a channel is given by equation (16.21) as

$$E = h + \frac{V^2}{2g}, \text{ where } V = \frac{Q}{A} = \frac{Q}{b \times h}$$

$$\therefore \quad E = h + \frac{Q^2}{b^2 \times h^2} \times \frac{1}{2g} = h + \frac{Q^2}{2gb^2h^2}$$

or $$Q^2 = (E - h)\, 2gb^2h^2 \quad \text{or} \quad Q = \sqrt{(E-h)2gb^2h^2} = b\sqrt{2g\left(Eh^2 - h^3\right)}$$

For maximum discharge, Q, the expression $(Eh^2 - h^3)$ should be maximum. Or in other words,

$$\frac{d}{dh}(Eh^2 - h^3) = 0 \quad \text{or} \quad 2Eh - 3h^2 = 0 \qquad (\because \ E \text{ is constant})$$

or $$2E - 3h = 0 \qquad \text{(Dividing by } h\text{)}$$

or $$h = \tfrac{2}{3}E \qquad ...(16.26)$$

or $$E = \frac{3h}{2} \qquad ...(i)$$

But from equation (16.25), specific energy is minimum when it is equal to $\frac{3}{2}$ times the value of depth of critical flow. Here in equation (i), the specific energy (E) is equal to $\frac{3}{2}$ times the depth of flow. Thus equation (i) represents the minimum specific energy and h is the critical depth. Hence the condition for maximum discharge for given value of specific energy is that the depth of flow should be critical.

Problem 16.36 *The specific energy for a 3 m wide channel is to be 3 kg-m/kg. What would be the maximum possible discharge ?*

Solution. Given :

Width of channel, $b = 3$ m

Specific energy, $E = 3$ kg-m/kg $= 3$ m

For the given value of specific energy, the discharge will be maximum, when depth of flow is critical. Hence from equation (16.26) for maximum discharge.

$$h_c = h = \tfrac{2}{3}\text{E} = \tfrac{2}{3} \times 3.0 = 2.0 \text{ m}$$

$\therefore$ Maximum discharge, Q_{max} is given by

$$Q_{max} = \text{Area} \times \text{Velocity} = (b \times \text{depth of flow}) \times \text{Velocity}$$
$$= (b \times h_c) \times V_c \quad (\because \text{ At critical depth, Velocity will be critical})$$

where V_c is critical velocity and it is given by equation (16.24),

$$V_c = \sqrt{g \times h_c} = \sqrt{9.81 \times 2.0} = 4.4249 \text{ m/s}$$

$\therefore$ $$Q_{max} = (b \times h_c) \times V_c = (3 \times 2) \times 4.4249 = \mathbf{26.576\ m^3/s.\ Ans.}$$

Problem 16.37 *The specific energy for a 5 m wide rectangular channel is to be 4 Nm/N. If the rate of flow of water through the channel is 20 m^3/s, determine the alternate depths of flow.*

Solution. Given :

Width of channel, $b = 5$ m

Specific energy, $E = 4$ Nm/N $= 4$ m

Discharge, $Q = 20\ m^3/s$

The specific energy (E) is given by equation (16.21) as,

$$E = h + \frac{V^2}{2g}, \quad \text{where } V = \frac{\text{Discharge}}{\text{Area}} = \frac{Q}{b \times h} = \frac{20}{5 \times h} = \frac{4}{h}$$

$\therefore$ Specific energy, $$E = h + \frac{V^2}{2g} = h + \left(\frac{4}{h}\right)^2 \times \frac{1}{2g} = h + \frac{8}{g \times h^2}$$

But $E = 4.0$

Equating the two values of E, $4 = h + \frac{8}{9.81 \times h^2} = h + \frac{0.8155}{h^2}$

$$4h^2 = h^3 + .8155 \quad \text{or} \quad h^3 - 4h^2 + .8155 = 0$$

This is a cubic equation. Solving by trial and error, we get

$h =$ **3.93 m and 0.48 m. Ans.**

▶ 16.8 HYDRAULIC JUMP OR STANDING WAVE

Consider the flow of water over a dam as shown in Fig. 16.27. The height of water at the section 1-1 is small. As we move towards downstream, the height or depth of water increases rapidly over a short length of the channel. This is because at the section 1-1, the flow is a *shooting flow* as the depth of water at section 1-1 is less than critical depth. Shooting flow is an unstable type of flow and does not continue on the downstream side. Then this shooting will convert itself into a streaming or tranquil flow and hence depth of water will increase. This sudden increase of depth of water is called a hydraulic jump or a standing wave. Thus hydraulic jump is defined as :

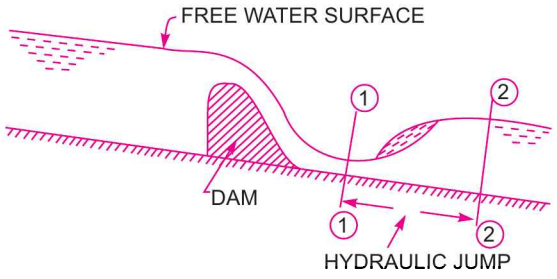

Fig. 16.27 *Hydraulic jump.*

"The rise of water level, which takes place due to the transformation of the unstable shooting flow (Super-critical) to the stable streaming flow (sub-critical flow)."

When hydraulic jump takes place, a loss of energy due to eddy formation and turbulence occurs.

16.8.1 Expression for Depth of Hydraulic Jump. Before deriving an expression for the depth of hydraulic jump, the following assumptions are made :

1. The flow is uniform and pressure distribution is due to hydrostatic before and after the jump.
2. Losses due to friction on the surface of the bed of the channel are small and hence neglected.
3. The slope of the bed of the channel is small, so that the component of the weight of the fluid in the direction of flow is negligibly small.

Consider a hydraulic jump formed in a channel of horizontal bed as shown in Fig. 16.28. Consider two sections 1-1 and 2-2 before and after hydraulic jump.

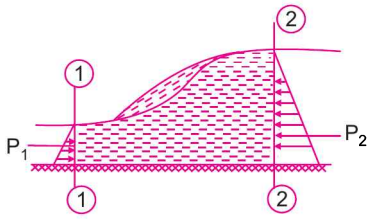

Fig. 16.28 *Hydraulic jump.*

Let d_1 = Depth of flow at section 1-1,
d_2 = Depth of flow at section 2-2,
V_1 = Velocity of flow at section 1-1,
V_2 = Velocity of flow at section 2-2,
$\bar{Z}_1$ = Depth of centroid of area at section 1-1 below free surface,
$\bar{Z}_2$ = Depth of centroid of area at section 2-2 below free surface,
A_1 = Area of cross-section at section 1-1, and
A_2 = Area of cross-section at section 2-2.

Consider unit width of the channel.

The forces acting on the mass of water between sections 1-1 and 2-2 are :

(*i*) Pressure force, P_1 on section 1-1,
(*ii*) Pressure force, P_2 on section 2-2,
(*iii*) Frictional force on the floor of the channel, which is assumed to be negligible.

Let q = discharge per unit width

$$= V_1 d_1 = V_2 d_2 \qquad ...(i)$$

Now pressure force P_1 on section 1-1

$$= \rho g A_1 \bar{Z}_1 = \rho g \times d_1 \times 1 \times \frac{d_1}{2}$$

$$= \frac{\rho g d_1^2}{2} \qquad \left(\because \quad A_1 = d_1 \times 1, \bar{Z}_1 = \frac{d_1}{2}\right)$$

Similarly pressure force on section 2-2,

$$P_2 = \rho g A_2 \bar{Z}_2$$

$$= \rho g \times d_2 \times 1 \times \frac{d_2}{2} = \frac{\rho g d_2^2}{2}$$

Net force acting on the mass of water between sections 1-1 and 2-2

$$= P_2 - P_1 \qquad | \because \quad P_2 \text{ is greater than } P_1 \text{ and } d_2 \text{ is greater than } d_1$$

$$= \frac{\rho g d_2^2}{2} - \frac{\rho g d_1^2}{2} = \frac{\rho g}{2} [d_2^2 - d_1^2] \qquad ...(ii)$$

But from momentum principle, the net force acting on a mass of fluid must be equal to the rate of change of momentum in the same section.

∴ Rate of change of momentum in the direction of force
= mass of water per sec × change of velocity in direction of force

Now mass of water per second = ρ × discharge per unit width × width
= ρ × q × 1 = ρq m^3/s

Change of velocity in the direction of force = $(V_1 - V_2)$

[as net force is acting from right to left, the change of velocity should be taken from right to left and hence is equal to $(V_1 - V_2)$]

∴ Rate of change of momentum in the direction of force = $\rho q(V_1 - V_2)$ ...(*iii*)

Hence according to momentum principle, the expression given by equation (*ii*) is equal to the expression given by equation (*iii*)

or $$\frac{\rho g}{2}(d_2^2 - d_1^2) = \rho q(V_1 - V_2)$$

But from equation (*i*), $V_1 = \frac{q}{d_1}$ and $V_2 = \frac{q}{d_2}$

∴ $$\frac{\rho g}{2}(d_2^2 - d_1^2) = \rho q\left(\frac{q}{d_1} - \frac{q}{d_2}\right)$$

or $$\frac{g}{2}(d_2 + d_1)(d_2 - d_1) = q^2\left(\frac{d_2 - d_1}{d_1 d_2}\right)$$ (Dividing by ρ)

or $$\frac{g}{2}(d_2 + d_1) = \frac{q^2}{d_1 d_2}$$ [Dividing by$(d_2 - d_1)$]

or $$(d_2 + d_1) = \frac{2q^2}{g d_1 d_2}$$ ...(*iv*)

Multiplying both sides by d_2, we get

$$d_2^2 + d_1 d_2 = \frac{2q^2}{g d_1} \quad \text{or} \quad d_2^2 + d_1 d_2 - \frac{2q^2}{g d_1} = 0$$ ...(*v*)

Equation (*v*) is a quadratic equation in d_2 and hence its solution is

$$d_2 = \frac{-d_1 \pm \sqrt{d_1^2 - 4 \times 1 \times \left(\frac{-2q^2}{g d_1}\right)}}{2 \times 1}$$

$$= \frac{-d_1 \pm \sqrt{d_1^2 + \frac{8q^2}{g d_1}}}{2} = -\frac{d_1}{2} \pm \sqrt{\frac{d_1^2}{4} + \frac{2q^2}{g d_1}}$$

The two roots of the equation are $-\frac{d_1}{2}-\sqrt{\frac{d_1^2}{4}+\frac{2q^2}{gd_1}}$ and $-\frac{d_1}{2}+\sqrt{\frac{d_1^2}{4}+\frac{2q^2}{gd_1}}$

First root is not possible as it gives –ve depth. Hence

$$d_2 = -\frac{d_1}{2}+\sqrt{\frac{d_1^2}{4}+\frac{2q^2}{gd_1}} \qquad ...(16.27)$$

$$= -\frac{d_1}{2}+\sqrt{\frac{d_1^2}{4}+\frac{2\times(V_1d_1)^2}{gd_1}} \qquad \{\because \quad q_1 = V_1d_1\}$$

$$= -\frac{d_1}{2}+\sqrt{\frac{d_1^2}{4}+\frac{2V_1^2d_1}{g}} \qquad ...(16.28)$$

$\therefore$ Depth of Hydraulic jump $= (d_2 - d_1)$. ...(16.29)

16.8.2 Expression for Loss of Energy Due to Hydraulic Jump. As mentioned in Art. 16.8 that when hydraulic jump takes place, a loss of energy due to eddies formation and turbulence occurs. This loss of energy is equal to the difference of specific energies at sections 1-1 and 2-2.

Or loss of energy due to hydraulic jump,

$$h_L = E_1 - E_2$$

$$= \left(d_1+\frac{V_1^2}{2g}\right)-\left(d_2+\frac{V_2^2}{2g}\right) \qquad \left(\because \quad E_1 = d_1+\frac{V_1^2}{2g} \text{ and so } E_2\right)$$

$$= \left(\frac{V_1^2}{2g}-\frac{V_2^2}{2g}\right)-(d_2-d_1)$$

$$= \left(\frac{q^2}{2gd_1^2}-\frac{q^2}{2gd_2^2}\right)-(d_2-d_1) \qquad \left(\because \quad V_1 = \frac{q}{d_1} \text{ and } V_2 = \frac{q}{d_2}\right)$$

$$= \frac{q^2}{2g}\left[\frac{1}{d_1^2}-\frac{1}{d_2^2}\right]-[d_2-d_1] = \frac{q^2}{2g}\left[\frac{d_2^2-d_1^2}{d_1^2d_2^2}\right]-[d_2-d_1] \qquad ...(vi)$$

But from equation (*iv*), $q^2 = gd_1d_2\frac{(d_2+d_1)}{2}$

Substituting the value of q^2 in equation (*vi*), we get

Loss of energy, $h_L = gd_1d_2\frac{(d_2+d_1)}{2}\times\frac{d_2^2-d_1^2}{2gd_1^2d_2^2}-(d_2-d_1) = \frac{(d_2+d_1)(d_2^2-d_1^2)}{4d_1d_2}-(d_2-d_1)$

$$= \frac{(d_2+d_1)(d_2+d_1)(d_2-d_1)}{4d_1d_2}-(d_2-d_1) = (d_2-d_1)\left[\frac{(d_2+d_1)^2}{4d_1d_2}-1\right]$$

$$= (d_2 - d_1)\left[\frac{d_2^2 + d_1^2 + 2d_1d_2 - 4d_1d_2}{4d_1d_2}\right] = (d_2 - d_1)\frac{[d_2 - d_1]^2}{4d_1d_2}$$

$$\therefore \qquad h_L = \frac{[d_2 - d_1]^3}{4d_1d_2}. \qquad \text{...(16.30)}$$

16.8.3 Expression for Depth of Hydraulic Jump in Terms of Upstream Froude Number.

Let V_1 = Velocity of flow on the upstream side,

and d = Depth of flow on upstream side,

Then Froude Number $(F_e)_1$ on the upstream side of the jump is given by

$$(F_e)_1 = \frac{V_1}{\sqrt{gd_1}} \qquad \text{...(vii)}$$

Now the depth of flow after the hydraulic jump is d_2 and it is given by equation (16.28) as

$$d_2 = -\frac{d_1}{2} + \sqrt{\frac{d_1^2}{4} + \frac{2V_1^2d_1}{g}} = -\frac{d_1}{2} + \sqrt{\frac{d_1^2}{4}\left(1 + \frac{8V_1^2}{gd_1}\right)}$$

$$= -\frac{d_1}{2} + \frac{d_1}{2}\sqrt{1 + \frac{8V_1^2}{gd_1}} \qquad \text{...(viii)}$$

But from equation (*vii*), $(F_e)_1 = \dfrac{V_1}{\sqrt{gd_1}}$ or $(F_e)_1^2 = \dfrac{V_1^2}{gd_1}$

Substituting this value in equation (*viii*), we get

$$d_2 = -\frac{d_1}{2} + \frac{d_1}{2}\sqrt{1 + 8(F_e)_1^2} = \frac{d_1}{2}\left(\sqrt{1 + 8(F_e)_1^2} - 1\right) \qquad \text{...(16.31)}$$

16.8.4 Length of Hydraulic Jump. This is defined as the length between the two sections where one section is taken before the hydraulic jump and the second section is taken immediately after the jump. For a rectangular channel from experiments, it has been found equal to 5 to 7 times the height of the hydraulic jump.

Problem 16.38 *The depth of flow of water, at a certain section of a rectangular channel of 4 m wide, is 0.5 m. This discharge through the channel is 16 m^3/s. If a hydraulic jump takes place on the downstream side, find the depth of flow after the jump.*

Solution. Given :

Width of channel, $b = 4$ m

Depth of flow before jump, $d_1 = 0.5$ m

Discharge, $Q = 16$ m^3/s

$\therefore$ Discharge per unit width, $q = \dfrac{Q}{b} = \dfrac{16}{4} = 4$ m^2/s

Let the depth of flow after jump = d_2

Depth of flow after the jump is given by equation (16.27), as

$$d_2 = -\frac{d_1}{2} + \sqrt{\frac{d_1^2}{4} + \frac{2q^2}{gd_1}} = -\frac{0.5}{2} + \sqrt{\frac{0.5^2}{4} + \frac{2 \times 4^2}{9.81 \times 0.5}}$$

$$= -0.25 + \sqrt{0.0625 + 6.5239} = -0.25 + 2.566 = \mathbf{2.316\ m.\ Ans.}$$

Problem 16.39 *The depth of flow of water, at a certain section of a rectangular channel of 2 m wide, is 0.3 m. The discharge through the channel is 1.5 m^3/s. Determine whether a hydraulic jump will occur, and if so, find its height and loss of energy per kg of water.*

Solution. Given :

Depth of flow, $d_1 = 0.3$ m

Width of channel, $b = 2$ m

Discharge, $Q = 1.5$ m^3/s

Discharge per unit width, $q = \frac{Q}{b} = \frac{1.5}{2.0} = 0.75$ m^2/s.

Hydraulic jump will occur if the depth of flow on the upstream side is less than the critical depth on upstream side or if the Froude number on the upstream side is more than one.

Critical depth (h_c) is given by equation (16.23) as

$$h_c = \left(\frac{q^2}{g}\right)^{1/3} = \left(\frac{0.75^2}{9.81}\right)^{1/3} = 0.3859$$

Now the depth on the upstream side is 0.3 m. This depth is less than critical depth and hence hydraulic jump will occur.

The depth of flow after hydraulic jump is given by equation (16.27) as

$$d_2 = -\frac{d_1}{2} + \sqrt{\frac{d_1^2}{4} + \frac{2q^2}{gd_1}} = -\frac{0.3}{2} + \sqrt{\frac{0.3^2}{4} + \frac{2 \times 0.75^2}{9.81 \times 0.3}}$$

$$= -1.5 + \sqrt{.0255 + .3822} = -0.15 + .6362 = 0.4862 \text{ m}$$

$\therefore$ Height of hydraulic jump $= d_2 - d_1 = 0.4862 - 0.30 =$ **0.1862 m. Ans.**

Loss of energy per kg of water due to hydraulic jump is given by equation (16.30) as

$$h_L = \frac{(d_2 - d_1)^3}{4d_1d_2} = \frac{[0.4862 - 0.30]^3}{4 \times .4862 \times .30}$$

$$= \frac{0.1862^3}{4 \times .4862 \times .30} = \textbf{0.01106 m-kg/kg. Ans.}$$

Problem 16.40 *A sluice gate discharges water into a horizontal rectangular channel with a velocity of 10 m/s and depth of flow of 1 m. Determine the depth of flow after the jump and consequent loss in total head.*

Solution. Given :

Velocity of flow before hydraulic jump, $V_1 = 10$ m/s

Depth of flow before hydraulic jump, $d_1 = 1$ m

Discharge per unit width, $q = V_1 \times d_1 = 10 \times 1 = 10$ m^2/s

The depth of flow after jump is given by equation (16.27) as

$$d_2 = -\frac{d_1}{2} + \sqrt{\frac{d_1^2}{4} + \frac{2q^2}{gd_1}} = -\frac{1.0}{2} + \sqrt{\frac{1^2}{4} + \frac{2 \times 10^2}{9.81 \times 1}}$$

$$= -0.50 + \sqrt{0.25 + 20.387} = \textbf{4.043 m. Ans.}$$

Loss in total head is given by equation (16.30) as

$$h_L = \frac{(d_2 - d_1)^3}{4d_1d_2} = \frac{(4.043 - 1.0)^3}{4 \times 1.0 \times 4.043} = \textbf{1.742 m. Ans.}$$

Problem 16.41 *A sluice gate discharges water into a horizontal rectangular channel with a velocity of 6 m/s and depth of flow is 0.4 m. The width of the channel is 8 m. Determine whether a hydraulic jump will occur, and if so, find its height and loss of energy per kg of water. Also determine the power lost in the hydraulic jump.*

Solution. (*i*) Given :

Velocity of flow, $V_1 = 6$ m/s

Depth of flow, $d_1 = 0.4$ m

Width of channel, $b = 8$ m

$\therefore$ Discharge per unit width, $q = \dfrac{Q}{b} = \dfrac{V_1 \times \text{area}}{b} = \dfrac{V_1 \times d_1 \times b}{b}$

$= V_1 \times d_1 = 6 \times 0.4 = 2.4$ m^2/s

Froude number on the upstream side,

$$(F_e)_1 = \frac{V_1}{\sqrt{gd_1}} = \frac{6.0}{\sqrt{9.81 \times 0.4}} = 3.0289 \simeq 3.029.$$

As Froude number is more than one, the flow is shooting on the upstream side. Shooting flow is unstable flow and it will convert itself into streaming flow by raising its height and hence hydraulic jump will take place.

(*ii*) Let the depth of hydraulic jump = d_2

Using equation (16.31), we have

$$d_2 = \frac{d_1}{2}\left(\sqrt{1 + 8(F_e)_1^2} - 1\right) = \frac{0.4}{2}\left(\sqrt{1 + 8 \times 3.029^2} - 1\right) = 1.525 \text{ m}$$

$\therefore$ Height of hydraulic jump $= d_2 - d_1 = 1.525 - 0.4 =$ **1.125 m. Ans.**

(*iii*) Loss of energy per kg of water is given by equation (16.30)

$$h_L = \frac{(d_2 - d_1)^3}{4d_1d_2} = \frac{(1.525 - 0.4)^3}{4 \times 0.4 \times 1.525} = \textbf{0.5835 m-kg/kg of water. Ans.}$$

(*iv*) Power lost in kW $= \dfrac{\rho g \times Q \times h_L}{1000}$, where $Q = V \times$ area

$= V_1 \times d_1 \times b = 6 \times 0.4 \times 8 = 19.2$ m^3/s

$\therefore$ Power, $P = \dfrac{1000 \times 9.81 \times 19.2 \times 0.5835}{1000} =$ **109.9 kW. Ans.**

Problem 16.42 *A hydraulic jump forms at the downstream end of spillway carrying 17.93 m^3/s discharge. If the depth before jump is 0.80 m, determine the depth after the jump and energy loss.*

Solution. Given :

Discharge $Q = 17.93$ m^3/s

Depth before jump, $d_1 = 0.8$ m

Taking width $b = 1$ m, we get

Discharge per unit width, $q = \dfrac{17.93}{1} = 17.93$

Let d_2 = Depth after jump and h_L = Loss of energy.

Using equation (16.27), we get $d_2 = -\dfrac{d_1}{2} + \sqrt{\dfrac{d_1^2}{4} + \dfrac{2q^2}{gd_1}} = -\dfrac{0.8}{2} + \sqrt{\dfrac{0.8^2}{4} + \dfrac{2 \times 17.93^2}{9.81 \times 0.8}}$

$$= -0.4 + \sqrt{0.16 + 81.927} = -0.4 + 9.06 = \textbf{8.66 m. Ans.}$$

Using equation (16.30) for loss of energy,

$$h_L = \frac{(d_2 - d_1)^3}{4 d_1 d_2} = \frac{(8.66 - 0.8)^3}{4 \times 0.8 \times 8.66} = \textbf{17.52 m. Ans.}$$

▶ 16.9 GRADUALLY VARIED FLOW (G.V.F.)

If the depth of flow in a channel changes gradually over a long length of the channel, the flow is said to be gradually varied flow and is denoted by G.V.F.

16.9.1 Equation of Gradually Varied Flow. Before deriving an equation for gradually varied flow, the following assumptions are made :

1. The bed slope of the channel is small,
2. The flow is steady and hence discharge Q is constant,
3. Accelerative effect is negligible and hence hydrostatic pressure distribution prevails over channel cross-section.
4. The energy correction factor, α is unity.
5. The roughness co-efficient is constant for the length of the channel and it does not depend on the depth of flow.
6. The formulae, such as Chezy's formula, Manning's formula, which are applicable, to the uniform flow are also applicable to the gradually varied flow for determining the slope of energy line.
7. The channel is prismatic.

Consider a rectangular channel having gradually varied flow as shown in Fig. 16.29. The depth of flow is gradually decreasing in the direction of flow.

Let Z = height of bottom of channel above datum
h = depth of flow,
V = mean velocity of flow,
i_b = slope of the channel bed,
i_e = slope of the energy line,
b = width of channel, and
Q = discharge through the channel

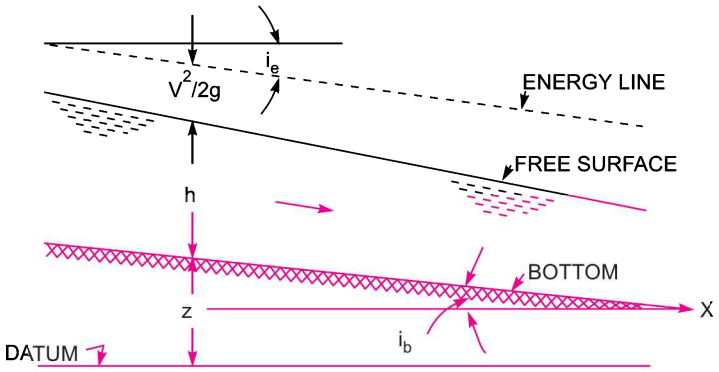

Fig. 16.29 *Equation for gradually varied flow.*

The energy equation at any section is given by Bernoulli's equation,

$$E = Z + h + \frac{V^2}{2g} \qquad ...(i)$$

Differentiating this equation with respect to x, where x is measured along the bottom of the channel in the direction of flow, we get

$$\frac{dE}{dx} = \frac{dZ}{dx} + \frac{dh}{dx} + \frac{d}{dx}\left(\frac{V^2}{2g}\right) \qquad ...(ii)$$

Now $$\frac{d}{dx}\left(\frac{V^2}{2g}\right) = \frac{d}{dx}\left(\frac{Q^2}{A^2 \times 2g}\right) \qquad \left(\because\ V = \frac{Q}{A} = \frac{Q}{b \times h}\right) \text{ (as } A = b \times h\text{)}$$

$$= \frac{d}{dx}\left(\frac{Q^2}{b^2h^2 \times 2g}\right) = \frac{Q^2}{b^2 \times 2g}\frac{d}{dx}\left(\frac{1}{h^2}\right) \text{ (} \because\ Q, b \text{ and } g \text{ are constant)}$$

$$= \frac{Q^2}{b^2 \times 2g}\frac{d}{dh}\left[\frac{1}{h^2}\right]\frac{dh}{dx} = \frac{Q^2}{b^2 \times 2g}\left[\frac{-2}{h^3}\right]\frac{dh}{dx} = \frac{-2Q^2}{b^2 \times 2gh^3}\frac{dh}{dx}$$

$$= -\frac{Q^2}{b^2h^2 \times gh}\frac{dh}{dx} = -\frac{V^2}{gh}\frac{dh}{dx} \qquad \left[\because\ \frac{Q}{bh} = V\right]$$

Substituting the value of $\frac{d}{dx}\left(\frac{V^2}{2g}\right)$ in equation (ii), we get

$$\frac{dE}{dx} = \frac{dZ}{dx} + \frac{dh}{dx} - \frac{V^2}{gh}\frac{dh}{dx} = \frac{dZ}{dx} + \frac{dh}{dx}\left[1 - \frac{V^2}{gh}\right] \qquad ...(iii)$$

Now $$\frac{dE}{dx} = \text{slope of the energy line} = -i_e$$

and $$\frac{dZ}{dx} = \text{slope of the bed of the channel} = -i_b$$

–ve sign with i_e and i_b is taken as with the increase of x, the value of E and Z decreases.

Substituting the value of $\frac{dE}{dx}$ and $\frac{dZ}{dx}$ in equation (iii), we get

$$-i_e = -i_b + \frac{dh}{dx}\left[1 - \frac{V^2}{gh}\right] \quad \text{or} \quad i_b - i_e = \frac{dh}{dx}\left[1 - \frac{V^2}{gh}\right]$$

or $$\frac{dh}{dx} = \frac{(i_b - i_e)}{\left[1 - \frac{V^2}{gh}\right]} \qquad ...(16.32)$$

$$= \frac{(i_b - i_e)}{[1 - (F_e)^2]} \qquad \left[\because\ \frac{V}{\sqrt{gh}} = F_e\right] \qquad ...(16.33)$$

As h is the depth of flow and x is the distance measured along the bottom of the channel hence $\frac{dh}{dx}$ represents the variation of the water depth along the bottom of the channel.

This is also called the slope of the free water surface. Thus :

(*i*) When $\frac{dh}{dx} = 0$, h is constant or depth of the water above the bottom of channel is constant. It means that free surface of water is parallel to the bed of the channel.

(*ii*) When $\frac{dh}{dx} > 0$ or $\frac{dh}{dx}$ is +ve, it means the depth of water increases in the direction of flow. The profile of the water so obtained is called *back water curve.*

(*iii*) When $\frac{dh}{dx} < 0$ or $\frac{dh}{dx}$ is –ve, it means that the depth of water decreases in the direction of flow. The profile of the water so obtained is called *drop down curve.*

Problem 16.43 *Find the rate of change of depth of water in a rectangular channel of 10 m wide and 1.5 m deep, when the water is flowing with a velocity of 1 m/s. The flow of water through the channel of bed slope 1 in 4000, is regulated in such a way that energy line is having a slope of .00004.*

Solution. Given :

Width of channel, $b = 10$ m

Depth of channel, $h = 3$ m

Velocity of flow, $V = 1$ m/s

Bed slope, $i_b = \frac{1}{4000} = .00025$

Slope of energy line, $i_e = .00004$

Let rate of change of depth of water = $\frac{dh}{dx}$

Using equation (16.32) as $\frac{dh}{dx} = \frac{(i_b - i_e)}{\left(1 - \frac{V^2}{gh}\right)} = \frac{.00025 - .00004}{\left(1 - \frac{1 \times 1}{9.81 \times 3}\right)} = \frac{.00021}{.966} =$ **.000217. Ans.**

Problem 16.44 *Find the slope of the free water surface in a rectangular channel of width 20 m, having depth of flow 5 m. The discharge through the channel is 50 m^3/s. The bed of the channel is having a slope of 1 in 4000. Take the value of Chezy's constant C = 60.*

Solution. Given :

Width of channel, $b = 20$ m

Depth of flow, $h = 5$ m

Discharge, $Q = 50$ m^3/s

Bed slope, $i_b = \frac{1}{4000} = .00025$

Chezy's constant, $C = 60$

The discharge, Q is given by $Q = V \times$ Area $= C\sqrt{mi} \times A = AC\sqrt{mi}$

where A = Area of flow $= b \times h = 20 \times 5 = 100$ m^2,

$$m = \text{hydraulic mean depth} = \frac{A}{P} = \frac{100}{b+2h} = \frac{100}{20+2\times5} = \frac{100}{30} = \frac{10}{3} \text{ m},$$

$i = i_e$ = slope of energy line.

The slope of the energy line* is determined from Chezy's formula

$$50 = 100 \times 60 \times \sqrt{\frac{10}{3} \times i_e} = 10954.45 \sqrt{i_e}$$

or
$$i_e = \left(\frac{50}{10954.45}\right)^2 = 0.0000208$$

The slope of free water surface $= \frac{dh}{dx}$

Using equation (16.32) as
$$\frac{dh}{dx} = \frac{i_b - i_e}{1 - \frac{V^2}{gh}} = \frac{0.00025 - 0.0000208}{1 - \frac{V^2}{9.81 \times 5.0}}$$

Now
$$V = \frac{Q}{\text{Area}} = \frac{50}{b \times h} = \frac{50}{20 \times 5} = 0.5$$

$$\frac{dh}{dx} = \frac{0.00025 - 0.0000208}{1 - \frac{0.5 \times 0.5}{9.81 \times 5.0}} = \frac{0.0002292}{0.9949} = \mathbf{0.00023. \text{ Ans.}}$$

16.9.2 Back Water Curve and Afflux. Consider the flow over a dam as shown in Fig. 16.30. On the upstream side of the dam, the depth of water will be rising. If there had not been any obstruction (such as dam) in the path of flow of water in the channel, the depth of water would have been constant as shown by dotted line parallel to the bed of the channel in Fig. 16.30. Due to obstruction, the water level rises and it has maximum depth from the bed at some section.

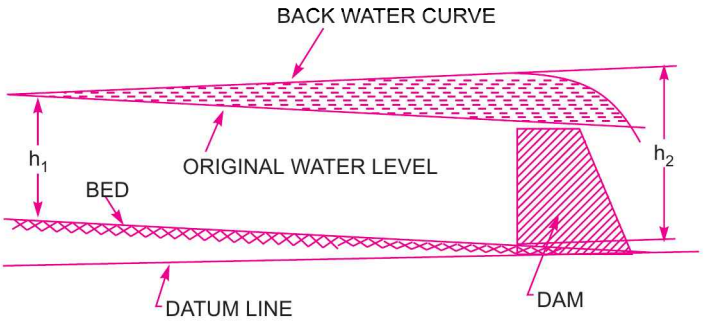

Fig. 16.30 *Back water curve and afflux.*

Let h_1 = depth of water at the point, where the water starts rising up, and
h_2 = maximum height of rising water from bed.

Then $(h_2 - h_1)$ = afflux. Thus *afflux* is defined as the maximum increase in water level due to obstruction in the path of flow of water. The profile of the rising water on the upstream side of the

* Please refer to Art. 16.9.1 point number 6.

dam is called *back water curve*. The distance along the bed of the channel between the section where water starts rising to the section where water is having maximum height is known as *length of back water curve*.

16.9.3 Expression for the Length of Back Water Curve. Consider the flow of water through a channel in which depth of water is rising as shown in Fig. 16.31. Let the two sections 1-1 and 2-2 are at such a distance that the distance between them represents the length of back water curve.

Let h_1 = depth of flow at section 1-1,

V_1 = velocity of flow at section 1-1,

h_2 = depth of flow at section 2-2,

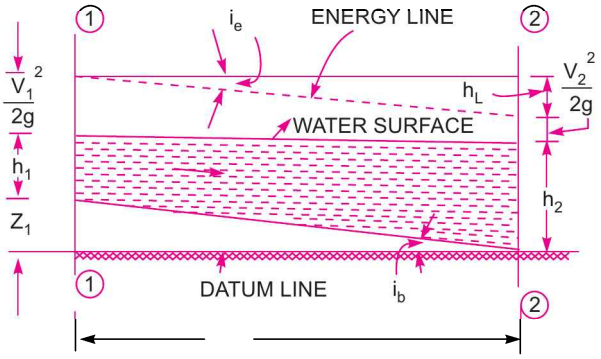

Fig. 16.31 *Length of back water curve.*

V_2 = velocity of flow at section 2-2,

i_b = bed slope,

i_e = energy line slope, and

L = length of back water curve.

Applying Bernoulli's equation at sections 1-1 and 2-2,

$$Z_1 + h_1 + \frac{V_1^2}{2g} = Z_2 + h_2 + \frac{V_2^2}{2g} + h_L \qquad ...(i)$$

where h_L = Loss of energy due to friction = $i_e \times L$

Also taking datum line passing through the bed of the channel at section 2-2. Then $Z_2 = 0$

$\therefore$ Equation (i) becomes as $Z_1 + h_1 + \frac{V_1^2}{2g} = h_2 + \frac{V_2^2}{2g} + i_e \times L$

From Fig. 16.31, $Z_1 = i_b \times L$

$\therefore$ $$i_b \times L + h_1 + \frac{V_1^2}{2g} = h_2 + \frac{V_2^2}{2g} + i_e \times L$$

or $$i_b \times L - i_e \times L = \left(h_2 + \frac{V_2^2}{2g}\right) - \left(h_1 + \frac{V_1^2}{2g}\right)$$

or $$L\,(i_b - i_e) = E_2 - E_1\,, \quad \text{where } E_2 = h_2 + \frac{V_2^2}{2g},\ E_1 = h_1 + \frac{V_1^2}{2g}$$

$$\therefore \qquad L = \frac{E_2 - E_1}{i_b - i_e}. \qquad \ldots(16.34)$$

Equation (16.34) is used to calculate the length of back water curve. The value of i_e (slope of energy line) is calculated either by Manning's formula or by Chezy's formula. The mean values of velocity, depth of flow, hydraulic mean depth etc., are used between sections 1-1 and 2-2 for calculating the value of i_e.

Problem 16.45 *Determine the length of the back water curve caused by an afflux of 2.0 m in a rectangular channel of width 40 m and depth 2.5 m. The slope of the bed is given as 1 in 11000. Take Manning's N = 0.03.*

Solution. Given :

Width of channel, $b = 40$ m

Afflux, $(h_2 - h_1) = 2.0$ m

Depth of channel, $h_1 = 2.5$ m

$\therefore \quad h_2 = 2.0 + 2.5 = 4.5$ m

Bed slope, $i_b = \dfrac{1}{11000} = 0.0000909$

Manning's, $N = 0.03$

Area of flow at section 1, $A_1 = b \times h_1 = 40 \times 2.5 = 100\ \text{m}^2$

Wetted perimeter, $P_1 = b + 2h_1 = 40 + 2 \times 2.5 = 45$ m

$\therefore$ Hydraulic mean depth, $m_1 = \dfrac{A_1}{P_1} = \dfrac{100}{45} = 2.22$ m

Using Manning's formula, $V = \dfrac{1}{N} . m^{2/3}\, i_b^{1/2}$

$\therefore$ Velocity at section 1, $V_1 = \dfrac{1}{N} m_1^{2/3}\, i_b^{1/2} = \dfrac{1}{0.03} \times 2.22^{2/3} \times 0.0000909^{1/2}$

$$= \frac{1}{0.03} \times 1.7 \times 0.009534 = 0.54 \text{ m/s}$$

Specific energy at section 1, $E_1 = \dfrac{V_1^2}{2g} + h_1 = \dfrac{0.54^2}{2 \times 9.81} + 2.5 = 2.5148$ m

From continuity, velocity at section 2 is given as

$$V_1 A_1 = V_2 \times A_2$$

$$\therefore \qquad V_2 = \frac{V_1 \times A_1}{A_2} = \frac{0.54 \times 100}{b \times h_2} = \frac{0.54 \times 100}{40 \times 4.5} = 0.3 \text{ m/s}$$

where area $A_2 = b \times h_2 = 40 \times 4.5 = 180\ \text{m}^2$

Wetted perimeter at section 2, $P_2 = b + 2h_2 = 40 + 2 \times 4.5 = 49$ m

$$\therefore \quad m_2 = \frac{A_2}{P_2} = \frac{180}{49} = 3.673 \text{ m}$$

Specific energy at section 2, $E_2 = h_2 + \frac{V_2^2}{2g} = 4.5 + \frac{0.3^2}{2 \times 9.81} = 4.504$ m

To find average velocity (V_{av}), first find average depth (h_{av}) as

$$h_{av} = \frac{h_1 + h_2}{2} = \frac{2.5 + 4.5}{2} = 3.5 \text{ m}$$

$$\therefore \quad V_{av} = \frac{V_1 A_1}{A_{av}} = \frac{V_1 \times b \times h_1}{b \times h_{av}} = \frac{V_1 \times h_1}{h_{av}} = \frac{0.54 \times 2.5}{3.5} = 0.3857 \text{ m/s}$$

Also $$m_{av} = \frac{m_1 + m_2}{2} = \frac{2.22 + 3.673}{2} = 2.9465$$

To find the value of i_e, use Manning's formula as

$$V_{av} = \frac{1}{N} m_{av}^{2/3} \times i_e^{1/2}$$

or $$0.3857 = \frac{1}{0.03} \times 2.9465^{2/3} \times i_e^{1/2} = 68.534\, i_e^{1/2}$$

or $$i_e = \left(\frac{0.3857}{68.534}\right)^2 = 0.00003167$$

The length of back water curve (L) is obtained from equation (16.34)

$$L = \frac{E_2 - E_1}{i_b - i_e} = \frac{4.504 - 2.5148}{0.0000909 - 0.00003167}$$

$$= \frac{1.9892}{0.00005923} = \textbf{33584.3 m. Ans.}$$

HIGHLIGHTS

1. If the depth of flow, velocity of flow, slope of the bed of channel and cross-section remain constant, the flow is called uniform, otherwise it is called non-uniform flow.
2. Non-uniform flow is also called varied flow. If the depth of flow changes abruptly over a small length of channel, the flow is called rapidly varied flow. If the depth of flow changes gradually over a long length of the channel, the flow is said to be gradually varied flow.
3. If Reynold number for open channel flow is less than 500, the flow is said to be laminar and if R_e is more than 2000, the flow is said to be turbulent.
4. If Froude number is less than 1.0, the flow is sub-critical or streaming. If $F_e = 1.0$, the flow is critical. If $F_e > 1.0$, the flow is super-critical or shooting.
5. Velocity of Chezy's formula is given as $V = C\sqrt{mi}$

where C = Chezy's constant, m = Hydraulic mean depth = $\frac{\text{Area}}{\text{Wetted perimeter}}$,

i = Slope of the bed.

6. The value of Chezy's constant, C is given by empirical formulae as :

(*i*) $C = \dfrac{157.6}{1.81 + \dfrac{K}{\sqrt{m}}}$ ... Bazin Formula

where K = Bazin's constant, m = Hydraulic mean depth

(*ii*) $C = \dfrac{23 + \dfrac{0.00155}{i} + \dfrac{1}{N}}{1 + \left(23 + \dfrac{0.00155}{i}\right)\dfrac{N}{\sqrt{m}}}$ ... Kutter's Formula

where N = Kutter's constant.

(*iii*) $C = \dfrac{1}{N} m^{1/6}$ ... Manning's Formula

where N = Manning's constant = Kutter's constant.

7. Most economical section is one that gives maximum discharge for a given values of cross-section area, slope of the bed and co-efficient of resistance.

8. Conditions for maximum discharge through :

(*a*) Rectangular section,

(*i*) $b = 2d$ (*ii*) $m = \dfrac{d}{2}$

(*b*) Trapezoidal section,

(*i*) Half of top width = Sloping side or $\dfrac{b + 2nd}{2} = d\sqrt{n^2 + 1}$

(*ii*) $m = \dfrac{d}{2}$

(*iii*) A semi-circle drawn from the mid-point of the top width with radius equal to depth of flow will touch the three sides of the channel.

9. Best side slope for most economical trapezoidal section is,

$$\theta = 60° \text{ or } n = \frac{1}{\sqrt{3}} = \frac{1}{\tan\theta}.$$

10. For circular sections, area cannot be maintained constant and hence there are two different conditions, one is for maximum velocity and other for maximum discharge.

11. Condition for maximum velocity through a circular channel is,

Depth of flow, d = 0.81 diameter of circular channel

Hydraulic mean depth, m = 0.305 diameter of circular channel

12. Condition for maximum discharge through a circular channel is,

Depth, d = 0.95 diameter of circular channel.

13. For a circular channel,

Wetted perimeter, $P = 2R\theta$

Area of flow, $A = R^2\left(\theta - \frac{\sin 2\theta}{2}\right)$

where R = Radius of circular channel,
θ = Half the angle subtended by the water surface at the centre.

14. Total energy of a flowing liquid per unit weight, Total energy = $z + h + V^2 / 2g$.

15. Specific energy of a flowing liquid per unit weight,

$$E = h + \frac{V^2}{2g}, \qquad \text{where } h = \text{Depth of flow, } V = \text{Velocity of flow.}$$

16. The depth of flow at which specific energy is minimum is called critical depth, which is given by

$$h_c = \left(\frac{q^2}{g}\right)^{1/3}, \quad \text{where } q = \text{discharge per unit width} = \frac{\text{Total discharge}}{b}.$$

17. The velocity of flow at critical depth is known as critical velocity, which is given as $V_c = \sqrt{g \times h_c}$.

18. Minimum specific energy is related with critical depth by the relation, $E_{\min} = \frac{3}{2} h_c$.

19. The flow corresponding to critical depth (or when Froude number is equal to 1.0) is known as critical flow.

20. If the depth of flow in a channel is greater than the critical depth (or Froude number is less than 1.0), the flow is said sub-critical or streaming flow.

21. If the depth of flow in a channel is less than the critical depth (or Froude number is more than 1.0), the flow is known as super-critical or shooting flow.

22. The condition for maximum discharge for a given value of specific energy is that the depth of flow should be critical.

23. The rise of water-level which takes place due to the transformation of the shooting to the streaming flow is known as hydraulic jump. The depth of flow after the jump is given by

$$d_2 = -\frac{d_1}{2} + \sqrt{\frac{d_1^2}{4} + \frac{2q^2}{gd_1}} \qquad \text{... (In terms of } q\text{)}$$

$$= -\frac{d_1}{2} + \sqrt{\frac{d_1^2}{4} + \frac{2V_1^2\, d_1}{g}} \qquad \text{... (In terms of } V_1\text{)}$$

$$= \frac{d_1}{2}\left(\sqrt{1 + 8(F_e)_1^2} - 1\right) \qquad \text{... (In terms of } F_{e_1}\text{)}$$

Depth of hydraulic jump, $= d_2 - d_1$

where d_1 = depth of flow before hydraulic jump,
V_1 = velocity of flow before hydraulic jump.

24. Energy lost due to hydraulic jump per kg of liquid

$$h_L = (E_1 - E_2) = \left(d_1 + \frac{V_1^2}{2g}\right) - \left(d_2 + \frac{V_2^2}{2g}\right) = \frac{(d_2 - d_1)^3}{4d_1 d_2}.$$

25. Equation of gradually varied flow, $\frac{dh}{dx} = \frac{i_b - i_e}{1 - \frac{V^2}{gh}}$ ... (In terms of V)

$$= \frac{i_b - i_e}{\left(1 - F_e^2\right)} \quad \text{... (In term of } F_e\text{)}$$

where $\frac{dh}{dx}$ = slope of free water surface, i_b = bed slope,

i_e = slope of the energy line, h = depth of flow, and V = velocity of flow.

26. Afflux is the increase in water level due to some obstruction across the flowing liquid, while back water curve is the profile of the rising water on the upstream side of the obstruction.

27. Length of back water curve is given by, $L = \frac{E_2 - E_1}{i_b - i_e}$

where E_1 = Specific energy at the section, where water starts rising = $h_1 + \frac{V_1^2}{2g}$

and E_2 = Specific energy at the end of the water curve = $h_2 + \frac{V_2^2}{2g}$.

EXERCISE

(A) THEORETICAL PROBLEMS

1. What do you understand by 'Flow in open channel' ?

2. Differentiate between : (*i*) Uniform flow and non-uniform flow, (*ii*) Steady and unsteady flow, (*iii*) Laminar and turbulent flow and (*iv*) Critical, sub-critical and super-critical flow in a open channel.

3. Explain the terms : (*i*) Rapidly varied flow and (*ii*) Gradually varied flow.

4. Derive an expression for the discharge through a channel by Chezy's formula.

5. Explain the terms : (*i*) Slope of the bed, (*ii*) Hydraulic mean depth and (*iii*) Wetted perimeter.

6. (*a*) What are the empirical formulae for determining the value of Chezy's constant ?

(*b*) What is the relation between Manning's constant and Chezy's constant.

7. State the following formulae for the values of C :

(*i*) Bazin's formulae, (*ii*) Kutter's formula, and (*iii*) Manning's formula.

8. (*a*) Define the term most economical section of a channel. What are the conditions for the rectangular channel of the best section ?

(*b*) What is meant by an economical section of a channel ?

9. Prove that for the trapezoidal channel of most economical section :

(*i*) Half of top width = Length of one of the sloping sides

(*ii*) Hydraulic mean depth = $\frac{1}{2}$ depth of flow.

10. (*a*) Derive the condition for the best side slope of the most economical trapezoidal channel.

(*b*) Find the side slope in a trapezoidal section of maximum efficiency which will carry the same flow as a half square section of the same area.

11. Prove that for a channel of circular section, the depth of flow,

$d = 0.81\ D$ for maximum velocity, and

$= 0.95\ D$ for maximum discharge,

where D = Diameter of circular channel, d = depth of flow.

12. Explain the terms : Specific energy of a flowing liquid, minimum specific energy, critical depth, critical velocity and alternate depths as applied to non-uniform flow.

13. What is specific energy curve ? Draw specific energy curve, and then derive expressions for critical depth and critical velocity.

14. (*a*) Derive an expression for critical depth and critical velocity.

(*b*) Define critical depth in an open channel in as many ways as you can.

15. Derive the condition for maximum discharge for a given value of specific energy.

16. Explain the term hydraulic jump. Derive an expression for the depth of hydraulic jump in terms of the upstream Froude number.

17. Derive an expression for the variation of depth along the length of the bed of the channel for gradually varied flow in an open channel. State clearly all the assumptions made.

18. Find an expression for loss of energy head for a hydraulic jump.

19. Define the terms : (*i*) Afflux and (*ii*) Back water curve. Prove that the length of the back water curve is given by,

$$L = \frac{(E_2 - E_1)}{i_b - i_e}$$

where L = Length of back water curve,

E_2 = Specific energy at the end of back water curve,

E_1 = Specific energy at the section where water starts rising,

i_b = Slope of bed, and i_e = Slope of the energy line.

20. Find, in terms of specific energy E, an expression for the critical depth in a trapezoidal channel with bottom width B and side slopes of 1 vertical to n horizontal.

21. Show that in a rectangular channel :

(*i*) Critical depth is two-third of specific energy, and

(*ii*) Froude number at critical depth is unity.

22. Obtain the condition for a trapezoidal channel with side slopes 2 H : 1 V to be most efficient for a given area A let B be its bed width.

23. By applying the momentum equation to open channel flow, show that the consequent depths and flow rate are related by $2q^2/g = y_1y_2\ (y_1 + y_2)$.

State the assumptions made in the derivation.

24. Derive the differential equation for steady gradually varied flow in open channels and list all assumptions.

$$\frac{dh}{dx} = \frac{(i_b - i_e)}{\left(1 - F_e^2\right)}.$$

25. What is the essential difference between gradually varied flow and rapidly varied flow ? Illustrate with neatly drawn sketches.

26. (*a*) Prove that the loss of energy head in a hydraulic jump is equal to $(d_2 - d_1)^3/4d_1d_2$, where d_1 and d_2 are the conjugate depths.

(*b*) Obtain the relationship between the Froude Numbers of flow before and after the hydraulic jump in a horizontal rectangular channel.

(B) NUMERICAL PROBLEMS

1. Find the velocity of flow and rate of flow of water through a rectangular channel of 5 m wide and 2 m deep, when it is running full. The channel is having bed slope of 1 in 3000. Take Chezy's constant $C = 50$. [**Ans.** 0.962 m/s, 9.62 m^3/s]
2. A flow of water of 150 litres per second flows down in a rectangular flume of width 70 cm and having adjustable bottom slope. If Chezy's constant C is 60, find the bottom slope necessary for uniform flow with a depth of flow of 40 cm. Also find the conveyance K of the flume. [**Ans.** 1 in 2341.5, 7.258]
3. Find the discharge through a trapezoidal channel of width 6 m and side slope of 1 horizontal to 3 vertical. The depth of flow of water is 3 m and Chezy's constant, $C = 60$. The slope of the bed of the channel is given 1 in 5000. [**Ans.** 23.26 m^3/s]
4. Find the rate of flow of water through a V-shaped channel having total angle between the sides as 60°. Take the value of $C = 50$ and slope of the bed 1 in 1500. The depth of flow is 6 m. [**Ans.** 32.864 m^3/s]
5. Find the discharge through a rectangular channel 3 m wide, having depth of water 2 m and bed slope as 1 in 1500. Take the value of $K = 2.36$ in Bazin's formula. [**Ans.** 5.184 m^3/s]
6. Find the discharge through the rectangular channel given in the above question, taking the value of $N = 0.012$ in Manning's formula. [**Ans.** 11.64 m^3/s]
7. Find the bed slope of trapezoidal channel of bed width 3 m, depth of water 2.5 m and side slope of 2 horizontal to 3 vertical, when the discharge through the channel is 10 m^3/s. Taking the value of $N = 0.03$ in Manning's formula

$$C = \frac{1}{N} m^{1/6}.$$

[**Ans.** 1 in 1803]

8. Find the diameter of a circular sewer pipe which is laid at a slope of 1 in 10000 and carries a discharge of 1000 litres/s when flowing half full. Take the value of Manning's $N = 0.02$. [**Ans.** 2.6 m]
9. A rectangular channel carries water at the rate of 500 litres/s when bed slope is 1 in 3000. Find the most economical dimensions of the channel if $C = 60$. [**Ans.** $b = 1.272$ m, $d = 0.636$ m]
10. A trapezoidal channel has side slopes of 1 horizontal to 2 vertical and the slope of the bed is 1 in 2000. The area of the section is 42 m^2. Find the dimensions of the section if it is most economical. Determine the discharge of the most economical section if $C = 60$. [**Ans.** $d = 4.918$ m, $b = 6.08$ m, $Q = 88.36$ m^3/s]
11. A trapezoidal channel with side slopes of 1 to 1 has to be designed to convey 9 m^3/s at a velocity of 1.5 m/s so that the amount of concrete lining for the bed and sides is the minimum. Calculate the area of lining required for one metre length of canal. [**Ans.** 6.62 m^2]
12. A power canal of trapezoidal section has to be excavated through hard clay at the least cost. Determine the dimensions of the channel given, discharge equal to 15 m^3/s, bed slope 1 : 2000 and Manning's, $N = 0.020$. [**Ans.** $b = 2.956$ m, $d = 2.56$ m]
13. Find the discharge through a circular pipe of diameter 4.0 m, if the depth of water in the pipe is 1.33 m and pipe is laid at a slope of 1 in 1500. Take the value of Chezy's constant = 60. [**Ans.** 4.89 m^3/s]
14. Water is flowing through a circular channel at the rate of 500 litres/s. The depth of water in the channel is 0.7 times the diameter and the slope of the bed of the channel is 1 in 8000. Find the diameters of the circular channel if the value of Manning's, $N = 0.015$. [**Ans.** 1.425 m]
15. The rate of flow of water through a circular channel of diameter 0.8 m is 200 litres/s. Find the slope of the bed of the channel for maximum velocity. Take $C = 50$. [**Ans.** 1/2787]
16. Determine the maximum discharge of water through a circular channel of diameter 2.0 m when the bed slope of the channel is 1 in 1500. Take $C = 50$. [**Ans.** 3.02 m^3/s]
17. The discharge of water through a rectangular channel of width 6 m, is 18 m^3/s when depth of flow of water is 2 m. Calculate : (*i*) specific energy of the flowing water, (*ii*) critical depth and critical velocity and (*iii*) value of minimum specific energy. [**Ans.** (*i*) 2.115 m, (*ii*) 0.971 m, 3.087 m/s, (*iii*) 1.457 m]

18. The specific energy for a 6 m wide rectangular channel is to be 5 kg-m/kg. If the rate of flow of water through the channel is 24 m^2/s, determine the alternate depths of flow. [**Ans.** 4.831 m, 0.169 m]

19. The depth of flow of water, at a certain section of a rectangular channel of 5 m wide is 0.6 m. The discharge through the channel is 15 m^3/s. If a hydraulic jump takes place on the downstream side, find the depth of flow after the jump. [**Ans.** 1.474 m]

20. For the Question 19, find the loss of energy per kg of water due to hydraulic jump. [**Ans.** 0.188 m]

21. A sluice gate discharges water into a horizontal rectangular channel with a velocity of 8 m/s and depth of flow is 0.5 m. The width of the channel is 6 m. Determine whether a hydraulic jump will occur, and if so, find its height and loss of energy per kg of water. Also determine the horse power lost in the hydraulic jump. [**Ans.** Yes, 1.816 m, 1.293 m, 413.76 h.p.]

22. Find the rate of change of depth of water in a rectangular channel of 12 m wide and 2 m deep, when the water is flowing with a velocity of 1.5 m/s. The flow of water through the channel of bed slope 1 in 300, is regulated in such a way that energy line is having a slope of 1 in 8000. [**Ans.** 0.000235]

23. Find the slope of the free water surface in a rectangular channel of width 15 m, having depth of flow 4 m. The discharge through the channel is 40 m^3/s. The bed of the channel is having a slope of 1 in 4000. Take the value of Chezy's constant, $C = 50$. [**Ans.** 0.000184]

24. Determine the length of the back water curve caused by an afflux of 1.5 m in a rectangular channel of width 50 m and depth 2.0 m. The slope of the bed is given as 1 in 2000. Take Manning's, $N = 0.03$. [**Ans.** 4566 m]

25. A trapezoidal channel with bottom slope 0.000169, bottom width 10 m and side slopes 1 : 1 carries 20 m^3/s when Manning's constant = 0.015. Determine the normal depth.

[**Hint.** $i = 0.000169$, $b = 10$ m, $n = 1$, $N = 0.015$, $Q = 20\ m^3/s$

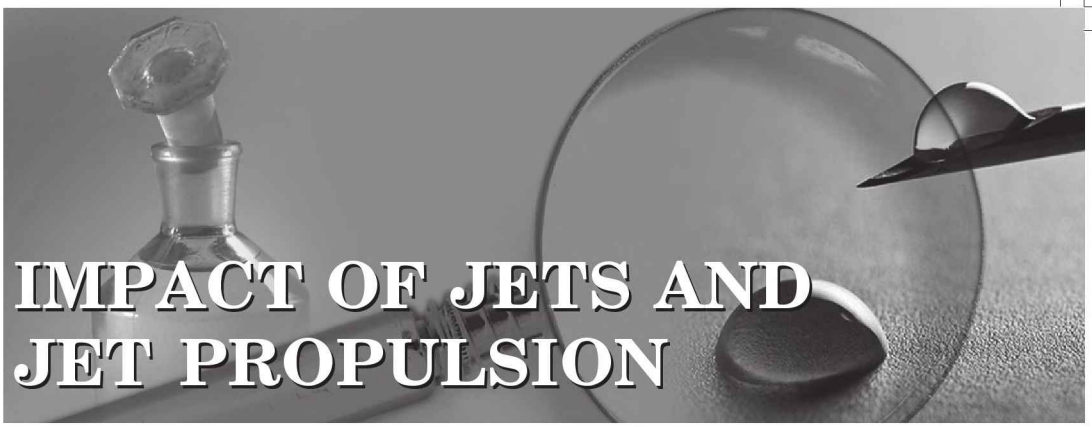
Use $$Q = \frac{1}{N} m^{2/3} \times i^{1/2} \times A, \text{ where } A = (b + nd) \times d = (10 + d)\, d$$

$$P = b + 2d\sqrt{1+n^2} = 10 + 2 \times \sqrt{2} \times d, m = \frac{(10+d)\,d}{\left(10 + 2\sqrt{2} \times d\right)}$$

$\therefore$ $$20 = \frac{1}{0.015} \times \left[\frac{(10+d)\,d}{\left(10 + 2\sqrt{2}\, d\right)}\right]^{2/3} \times 0.000169^{1/2} \times (10+d)\,d$$

or $$\frac{\left[(10+d)\,d\right]^{5/3}}{\left[10 + 2\sqrt{2}\, d\right]^{2/3}} = 23.$$ Find 'd' by hit and trial. [$d = 1.65$ m]]

17 CHAPTER



IMPACT OF JETS AND JET PROPULSION

▶ 17.1 INTRODUCTION

The liquid comes out in the form of a jet from the outlet of a nozzle, which is fitted to a pipe through which the liquid is flowing under pressure. If some plate, which may be fixed or moving, is placed in the path of the jet, a force is exerted by the jet on the plate. This force is obtained from Newton's second law of motion or from impulse-momentum equation. Thus impact of jet means the force exerted by the jet on a plate which may be stationary or moving. In this chapter, the following cases of the impact of jet *i.e.,* the force exerted by the jet on a plate, will be considered :

1. Force exerted by the jet on a stationary plate when
   (*a*) Plate is vertical to the jet, (*b*) Plate is inclined to the jet, and (*c*) Plate is curved.
2. Force exerted by the jet on a moving plate, when
   (*a*) Plate is vertical to the jet, (*b*) Plate is inclined to the jet, and (*c*) Plate is curved.

▶ 17.2 FORCE EXERTED BY THE JET ON A STATIONARY VERTICAL PLATE

Consider a jet of water coming out from the nozzle, strikes a flat vertical plate as shown in Fig. 17.1

Let V = velocity of the jet, d = diameter of the jet,

a = area of cross-section of the jet = $\frac{\pi}{4} d^2$.

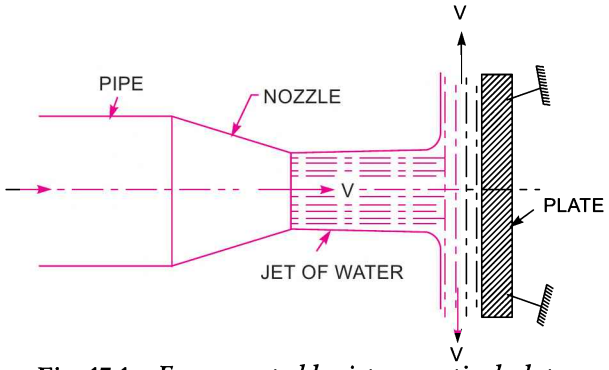


Fig. 17.1 *Force exerted by jet on vertical plate.*

The jet after striking the plate, will move along the plate. But the plate is at right angles to the jet. Hence the jet after striking, will get deflected through 90°. Hence the component of the velocity of jet, in the direction of jet, after striking will be zero.

The force exerted by the jet on the plate in the direction of jet,

$$F_x = \text{Rate of change of momentum in the direction of force}$$

$$= \frac{\text{Initial momentum} - \text{Final momentum}}{\text{Time}}$$

$$= \frac{(\text{Mass} \times \text{Initial velocity} - \text{Mass} \times \text{Final velocity})}{\text{Time}}$$

$$= \frac{\text{Mass}}{\text{Time}} [\text{Initial velocity} - \text{Final velocity}]$$

$$= (\text{Mass/sec}) \times (\text{velocity of jet before striking} - \text{velocity of jet after striking})$$

$$= \rho a V[V - 0] \qquad (\because \text{mass/sec} = \rho \times a\ V)$$

$$= \rho a V^2 \qquad \ldots(17.1)$$

For deriving above equation, we have taken initial velocity minus final velocity and not final velocity minus initial velocity. If the force exerted on the jet is to be calculated then final minus initial velocity is taken. But if the force exerted by the jet on the plate is to be calculated, then initial velocity minus final velocity is taken.

Note. In equation (17.1), if the value of density (ρ) is taken in S.I. units (*i.e.*, kg/m^3), the force (F_x) will be in Newton (N). The value of ρ for water in S.I. units is equal to 1000 kg/m^3.

17.2.1 Force Exerted by a Jet on Stationary Inclined Flat Plate. Let a jet of water, coming out from the nozzle, strikes an inclined flat plate as shown in Fig. 17.2.

Let V = Velocity of jet in the direction of x,

θ = Angle between the jet and plate,

a = Area of cross-section of the jet.

Then mass of water per sec striking the plate = $\rho \times aV$.

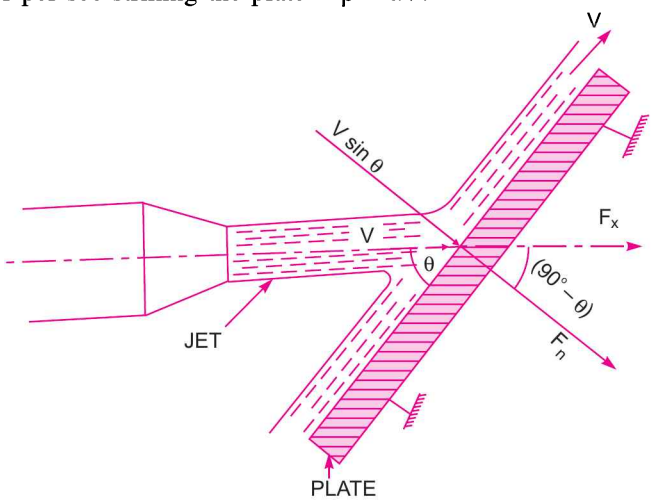

Fig. 17.2 *Jet striking stationary inclined plate.*

If the plate is smooth and if it is assumed that there is no loss of energy due to impact of the jet, then jet will move over the plate after striking with a velocity equal to initial velocity *i.e.*, with a velocity V. Let us find the force exerted by the jet on the plate in the direction normal to the plate. Let this force is represented by F_n

Then F_n = mass of jet striking per second
× [Initial velocity of jet before striking in the direction of n
– Final velocity of jet after striking in the direction of n]
$= \rho aV\ [V \sin \theta - 0\ ] = \rho aV^2 \sin \theta$ ...(17.2)

This force can be resolved into two components, one in the direction of the jet and other perpendicular to the direction of flow. Then we have,

F_x = component of F_n in the direction of flow
$= F_n \cos (90° - \theta) = F_n \sin \theta = \rho A\ V^2 \sin \theta \times \sin \theta$ $(\therefore\ F_n = \rho aV^2 \sin \theta)$
$= \rho AV^2 \sin^2 \theta$ ...(17.3)

And, F_y = component of F_n, perpendicular to flow
$= F_n \sin (90° - \theta) = F_n \cos \theta = \rho AV^2 \sin \theta \cos \theta.$ ...(17.4)

17.2.2 Force Exerted by a Jet on Stationary Curved Plate

(A) Jet strikes the curved plate at the centre. Let a jet of water strikes a fixed curved plate at the centre as shown in Fig. 17.3. The jet after striking the plate, comes out with the same velocity if the plate is smooth and there is no loss of energy due to impact of the jet, in the tangential direction of the curved plate. The velocity at outlet of the plate can be resolved into two components, one in the direction of jet and other perpendicular to the direction of the jet.

Component of velocity in the direction of jet = $- V \cos \theta$.

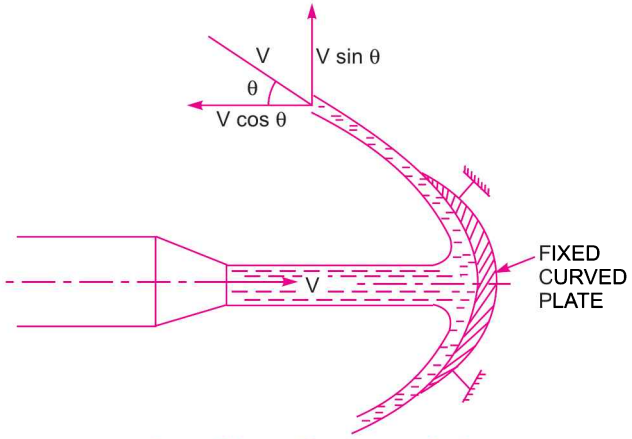

Fig. 17.3 *Jet striking a fixed curved plate at centre.*

(–ve sign is taken as the velocity at outlet is in the opposite direction of the jet of water coming out from nozzle).

Component of velocity perpendicular to the jet = $V \sin \theta$

Force exerted by the jet in the direction of jet,

$$F_x = \text{Mass per sec} \times [V_{1x} - V_{2x}]$$

where V_{1x} = Initial velocity in the direction of jet = V

V_{2x} = Final velocity in the direction of jet = $- V \cos \theta$

$\therefore$ $F_x = \rho aV[V - (-V\cos\theta)] = \rho aV[V + V\cos\theta]$

$= \rho aV^2[1 + \cos\theta]$ ...(17.5)

Similarly, F_y = Mass per sec $\times [V_{1y} - V_{2y}]$

where V_{1y} = Initial velocity in the direction of $y = 0$

V_{2y} = Final velocity in the direction of $y = V\sin\theta$

$\therefore$ $F_y = \rho aV[0 - V\sin\theta] = -\rho aV^2\sin\theta$ ...(17.6)

–ve sign means that force is acting in the downward direction. In this case the angle of deflection of the jet $= (180° - \theta)$ ...[17.6 (*A*)]

(B) Jet strikes the curved plate at one end tangentially when the plate is symmetrical. Let the jet strikes the curved fixed plate at one end tangentially as shown in Fig. 17.4. Let the curved plate is symmetrical about x-axis. Then the angle made by the tangents at the two ends of the plate will be same.

Let V = Velocity of jet of water,

θ = Angle made by jet with x-axis at inlet tip of the curved plate.

If the plate is smooth and loss of energy due to impact is zero, then the velocity of water at the outlet tip of the curved plate will be equal to V. The forces exerted by the jet of water in the directions of x and y are

F_x = (mass/sec) $\times [V_{1x} - V_{2x}]$

$= \rho aV[V\cos\theta - (-V\cos\theta)]$

$= \rho aV[V\cos\theta + V\cos\theta]$

$= 2\rho aV^2\cos\theta$ ...(17.7)

$F_y = \rho aV[V_{1y} - V_{2y}]$

$= \rho aV[V\sin\theta - V\sin\theta] = 0$

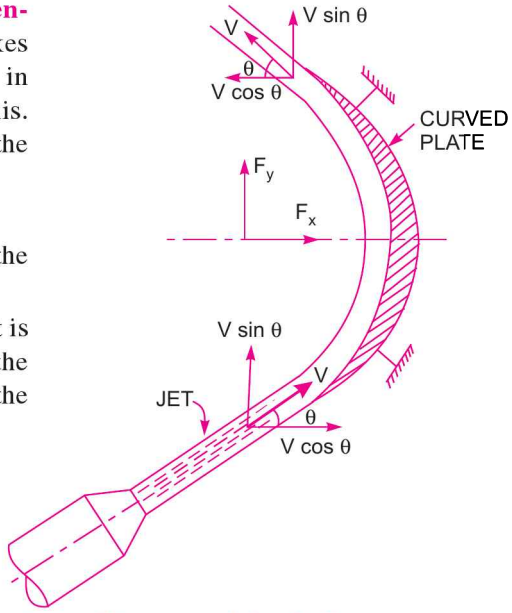

Fig. 17.4 *Jet striking curved fixed plate at one end.*

(C) Jet strikes the curved plate at one end tangentially when the plate is unsymmetrical. When the curved plate is unsymmetrical about x-axis, then angle made by the tangents drawn at the inlet and outlet tips of the plate with x-axis will be different.

Let θ = angle made by tangent at inlet tip with x-axis,

ϕ = angle made by tangent at outlet tip with x-axis.

The two components of the velocity at inlet are

$V_{1x} = V\cos\theta$ and $V_{1y} = V\sin\theta$

The two components of the velocity at outlet are

$V_{2x} = -V\cos\phi$ and $V_{2y} = V\sin\phi$

$\therefore$ The forces exerted by the jet of water in the directions of x and y are

$F_x = \rho aV[V_{1x} - V_{2x}] = \rho aV[V\cos\theta - (-V\cos\phi)]$

$= \rho aV[V\cos\theta + V\cos\phi] = \rho aV^2[\cos\theta + \cos\phi]$ ...(17.8)

$F_y = \rho aV[V_{1y} - V_{2y}] = \rho aV[V\sin\theta - V\sin\phi]$

$= \rho aV^2[\sin\theta - \sin\phi]$. ...(17.9)

Problem 17.1 *Find the force exerted by a jet of water of diameter 75 mm on a stationary flat plate, when the jet strikes the plate normally with velocity of 20 m/s.*

Solution. Given :

Diameter of jet, $d = 75 \text{ mm} = 0.075 \text{ m}$

$\therefore$ Area, $a = \frac{\pi}{4} d^2 = \frac{\pi}{4} (.075)^2 = .004417 \text{ m}^2$

Velocity of jet, $V = 20 \text{ m/s}$.

The force exerted by the jet of water on a stationary vertical plate is given by equation (17.1) as

$$F = \rho a V^2 \quad \text{where } \rho = 1000 \text{ kg/m}^3$$

$\therefore$ $F = 1000 \times .004417 \times 20^2 \text{ N} =$ **1766.8 N. Ans.**

Problem 17.2 *Water is flowing through a pipe at the end of which a nozzle is fitted. The diameter of the nozzle is 100 mm and the head of water at the centre nozzle is 100 m. Find the force exerted by the jet of water on a fixed vertical plate. The co-efficient of velocity is given as 0.95.*

Solution. Given :

Diameter of nozzle, $d = 100 \text{ mm} = 0.1 \text{ m}$

Head of water, $H = 100 \text{ m}$

Co-efficient of velocity, $C_v = 0.95$

Area of nozzle, $a = \frac{\pi}{4} (.1)^2 = .007854 \text{ m}^2$

Theoretical velocity of jet of water is given as

$$V_{th} = \sqrt{2gH} = \sqrt{2 \times 9.81 \times 100} = 44.294 \text{ m/s}$$

But $$C_v = \frac{\text{Actual velocity}}{\text{Theoretical velocity}}$$

$\therefore$ Actual velocity of jet of water, $V = C_v \times V_{th} = 0.95 \times 44.294 = 42.08$ m/s.

Force on a fixed vertical plate is given by equation (17.1) as

$$F = \rho a V^2 = 1000 \times .007854 \times 42.08^2 \quad (\because \text{ In S.I. units } \rho \text{ for water} = 1000 \text{ kg/m}^3)$$

$$= 13907.2 \text{ N} = \textbf{13.9 kN. Ans.}$$

Problem 17.3 *A jet of water of diameter 75 mm moving with a velocity of 25 m/s strikes a fixed plate in such a way that the angle between the jet and plate is 60°. Find the force exerted by the jet on the plate (i) in the direction normal to the plate and (ii) in the direction of the jet.*

Solution. Given :

Diameter of jet, $d = 75 \text{ mm} = 0.075 \text{ m}$

$\therefore$ Area, $a = \frac{\pi}{4} d^2 = \frac{\pi}{4} (.075)^2 = 0.004417 \text{ m}^2$

Velocity of jet, $V = 25 \text{ m/s}$.

Angle between jet and plate $\theta = 60°$

(*i*) The force exerted by the jet of water in the direction normal to the plate is given by equation (17.2) as

$$F_n = \rho a V^2 \sin \theta$$

$$= 1000 \times .004417 \times 25^2 \times \sin 60° = \textbf{2390.7 N. Ans.}$$

(*ii*) The force in the direction of the jet is given by equation (17.3),

$$F_x = \rho a V^2 \sin^2 \theta$$

$$= 1000 \times .004417 \times 25^2 \times \sin^2 60° = \textbf{2070.4 N. Ans.}$$

Problem 17.4 *A jet of water of diameter 50 mm strikes a fixed plate in such a way that the angle between the plate and the jet is 30°. The force exerted in the direction of the jet is 1471.5 N. Determine the rate of flow of water.*

Solution. Given :

Diameter of jet, $d = 50 \text{ mm} = 0.05 \text{ m}$

$\therefore$ Area, $a = \frac{\pi}{4} (.05)^2 = .001963 \text{ m}^2$

Angle, $\theta = 30°$

Force in the direction of jet, $F_x = 1471.5 \text{ N}$

Force in the direction of jet is given by equation (17.3) as $F_x = \rho a V^2 \sin^2 \theta$

As the force is given in Newton, the value of ρ should be taken equal to 1000 kg/m^3

$\therefore$ $1471.5 = 1000 \times .001963 \times V^2 \times \sin^2 30° = .05\ V^2$

$\therefore$ $V^2 = \frac{150}{.05} = 3000.0$

$V = 54.77 \text{ m/s}$

$\therefore$ Discharge, $Q = \text{Area} \times \text{Velocity}$

$= .001963 \times 54.77 = 0.1075 \text{ m}^3/\text{s} = \textbf{107.5 liters/s. Ans.}$

Problem 17.5 *A jet of water of diameter 50 mm moving with a velocity of 40 m/s, strikes a curved fixed symmetrical plate at the centre. Find the force exerted by the jet of water in the direction of the jet, if the jet is deflected through an angle of 120° at the outlet of the curved plate.*

Solution. Given :

Diameter of the jet, $d = 50 \text{ mm} = 0.05 \text{ m}$

$\therefore$ Area, $a = \frac{\pi}{4} (.05)^2 = 0.001963 \text{ m}^2$

Velocity of jet, $V = 40 \text{ m/s}$

Angle of deflection $= 120°$

From equation [17.6 (*A*)], the angle of deflection $= 180° - \theta$

$\therefore$ $180° - \theta = 120°$ or $\theta = 180° - 120° = 60°$

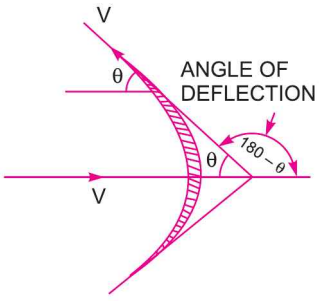

Fig. 17.5

Force exerted by the jet on the curved plate in the direction of the jet is given by equation (17.5) as

$$F_x = \rho a V^2 [1 + \cos \theta]$$

$$= 1000 \times .001963 \times 40^2 \times [1 + \cos 60°] = \textbf{4711.15 N. Ans.}$$

Problem 17.6 *A jet of water of diameter 75 mm moving with a velocity of 30 m/s, strikes a curved fixed plate tangentially at one end at an angle of 30° to the horizontal. The jet leaves the plate at an angle of 20° to the horizontal. Find the force exerted by the jet on the plate in the horizontal and vertical direction.*

Solution. Given :

Diameter of the jet, $d = 75 \text{ mm} = 0.075 \text{ m}$

$\therefore$ Area, $a = \frac{\pi}{4} (.075)^2 = .004417 \text{ m}^2$

Velocity of jet, $V = 30 \text{ m/s}$

Angle made by the jet at inlet tip with horizontal, $\theta = 30°$

Angle made by the jet at outlet tip with horizontal, $\phi = 20°$

The force exerted by the jet of water in the direction of x is given by equation (17.8) and in the direction of y by equation (17.9),

$\therefore$ $F_x = \rho a V^2 [\cos \theta + \cos \phi]$

$= 1000 \times .004417 [\cos 30° + \cos 20°] \times 30^2 =$ **7178.2 N. Ans.**

and $F_y = \rho a V^2 [\sin \theta - \sin \phi]$

$= 1000 \times .004417 [\sin 30° - \sin 20°] \times 30^2 =$ **628.13 N. Ans.**

▶ 17.3 FORCE EXERTED BY A JET ON A HINGED PLATE

Consider a jet of water striking a vertical plate at the centre which is hinged at O. Due to the force exerted by the jet on the plate, the plate will swing through some angle about the hinge as shown in Fig. 17.6

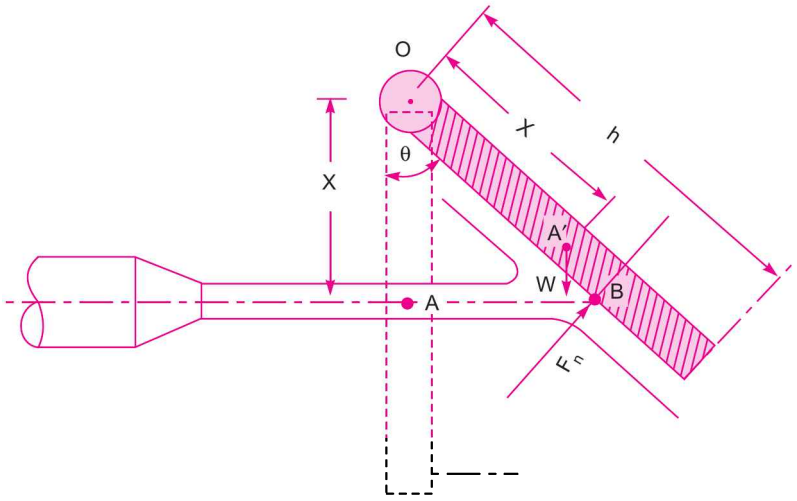

Fig. 17.6 *Force on a hinged plate.*

Let x = distance of the centre of jet from hinge O,

θ = angle of swing about hinge,

W = weight of plate acting at C.G. of the plate.

The dotted lines show the position of the plate, before the jet strikes the plate. The point A on the plate will be at A' after the jet strikes the plate. The distance $OA = OA' = x$. Let the weight of the plate is acting at A'. When the plate is in equilibrium after the jet strikes the plate, the moment of all the forces about the hinge must be zero. Two forces are acting on the plate. They are :

1. Force due to jet of water, normal to the plate,

$$F_n = \rho a V^2 \sin \theta'$$

where θ' = Angle between jet and plate = $(90° - \theta)$

2. Weight of the plate, W

Moment of force F_n about hinge = $F_n \times OB = \rho a V^2 \sin (90° - \theta) \times OB = \rho a V^2 \cos \theta \times OB$

$$= \rho a V^2 \cos \theta \times \frac{OA}{\cos \theta} = \rho a V^2 \times OA = \rho a V^2 \times x$$

Moment of weight W about hinge $= W \times OA' \sin \theta = W \times x \times \sin \theta$

For equilibrium of the plate, $\rho a V^2 \times x = W \times x \times \sin \theta$

$$\therefore \qquad \sin \theta = \frac{\rho a V^2}{W} \qquad \ldots(17.10)$$

From equation (17.10), the angle of swing of the plate about hinge can be calculated.

Problem 17.7 *A jet of water of 2.5 cm diameter, moving with a velocity of 10 m/s, strikes a hinged square plate of weight 98.1 N at the centre of the plate. The plate is of uniform thickness. Find the angle through which the plate will swing.*

Solution. Given :

Diameter of jet, $d = 2.5$ cm $= 0.025$ m

Velocity of jet, $V = 10$ m/s

Weight of plate, $W = 98.1$ N

Area of jet, $a = \frac{\pi}{4} d^2 = \frac{\pi}{4} \times (.025)^2 = .00049 \text{ m}^2$

The angle through which the plate will swing is given by equation (17.10) as

$$\sin \theta = \frac{\rho a V^2}{W} = 1000 \times \frac{.00049 \times 10^2}{98.1} \qquad (\because \quad \rho = 1000)$$

$$= .499$$

$$\therefore \qquad \theta = \mathbf{29.96°. \text{ Ans.}}$$

Problem 17.8 *A jet of water of 30 mm diameter strikes a hinged square plate at its centre with a velocity of 20 m/s. The plate is deflected through an angle of 20°. Find the weight of the plate.*

If the plate is not allowed, to swing, what will be the force required at the lower edge of the plate to keep the plate in vertical position.

Solution. Given :

Diameter of the jet, $d = 30$ mm $= 3$ cm $= 0.03$ m

$\therefore$ Area, $a = \frac{\pi}{4} d^2 = \frac{\pi}{4} (.03)^2 = .0007068 \text{ m}^2$

Velocity of jet, $V = 20$ m/s

Angle of swing, $\theta = 20°$

Using equation (17.10) for angle of swing,

$$\sin\theta = \frac{\rho a V^2}{W}$$

or $$\sin 20^\circ = 1000 \times \frac{.0007068 \times 20^2}{W} = \frac{282.72}{W}$$

$$\therefore \quad W = \frac{282.72}{\sin 20^\circ} = 826.6 \text{ N}$$

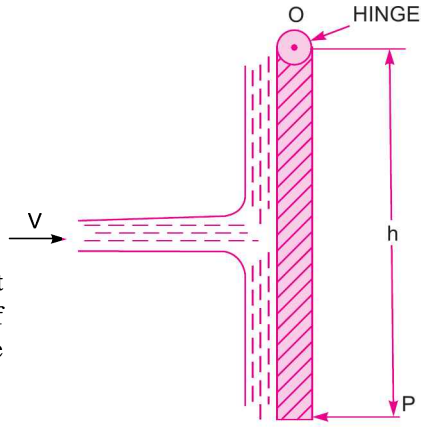

Fig. 17.7

If the plate is not allowed to swing, a force P will be applied at the lower edge of the plate as shown in Fig. 17.7. The weight of the plate is acting vertically downward through the C.G. of the plate.

Let F = Force exerted by jet of water

h = Height of plate

= Distance of P from the hinge.

The jet strikes at the centre of the plate and hence distance of the centre of the jet from hinge = $\frac{h}{2}$.

Taking moments* about the hinge, O, $P \times h = F \times \frac{h}{2}$.

$$\therefore \quad P = \frac{F \times h}{2 \times h} = \frac{F}{2} = \frac{\rho a V^2}{2} \qquad \left(\because \quad F = \rho a V^2\right)$$

$$= 1000 \times \frac{.0007068 \times 20^2}{2} = \textbf{141.36 N. Ans.}$$

Problem 17.9 *A rectangular plate, weighing 58.86 N is suspended vertically by a hinge on the top of horizontal edge. The centre of gravity of the plate is 10 cm from the hinge. A horizontal jet of water 2 cm diameter, whose axis is 15 cm below the hinge impinges normally on the plate with a velocity of 5 m/s. Find the horizontal force applied at the centre of the gravity to maintain the plate in its vertical position. Find the corresponding velocity of the jet, if the plate is deflected through 30° and the same force continues to act at the centre of gravity of the plate.*

Solution. Given :

Weight of plate, $W = 58.86$ N

Distance of W from hinge, $x = 10$ cm $= 0.1$ m

Diameter of jet, $d = 2$ cm $= 0.02$ m

$\therefore$ Area, $$a = \frac{\pi}{4} d^2 = \frac{\pi}{4} \times .02^2 = .000314 \text{ m}^2$$

Distance of the axis of the jet of water from hinge = 15 cm = 0.15 m

Velocity of jet, $V = 5$ m/s

(*i*) Let the force applied at the centre of gravity of the plate to keep the plate in vertical position = P as shown in Fig. 17.8 (*a*).

* The weight of the plate is passing through the hinge O. Hence moment of W about hinge is zero.

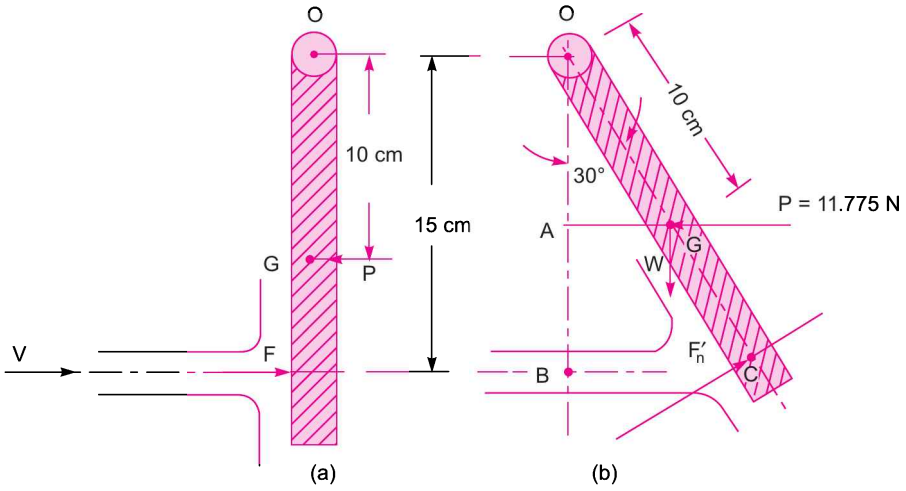

Fig. 17.8

The force exerted by a jet of water on the vertical plate,

$$F = \rho a V^2 = 1000 \times .000314 \times 5^2 = 7.85 \text{ N}$$

This force F is acting at a distance of 15 cm or 0.15 m from the hinge. Taking moments about hinge, we get

$$F \times 0.15 = P \times 0.10$$

$$\therefore \quad P = \frac{F \times 0.15}{0.10} = \frac{7.85 \times .15}{.10} = \textbf{11.775 N. Ans.}$$

(*ii*) The plate is deflected through an angle of 30° as shown in Fig. 17.8(*b*).

$\therefore$ Angle of swing = 30°

The force at the C.G. = P = 11.775 N

Let the velocity of the jet in this position = V m/s

For the deflected position of the plate as shown in Fig. 17.8 (*b*), the plate is in equilibrium under the action of three forces, which are :

(*i*) Weight of the plate, W acting at G at a distance 10 cm from O.

(*ii*) Horizontal force, P acting at G.

(*iii*) Normal force F_n' on the plate due to jet of water.

The angle between the jet and the plate, $\theta = 90° - 30° = 60°$

Hence, F_n' is given by equation (17.2) as

$$F_n' = \rho a V^2 \sin \theta = \rho a V^2 \sin 60°$$
$$= 1000 \times .000314 \times V^2 \times \sin 60° = 0.2717\ V^2$$

Taking moments of all forces about hinge O, we get

$$F_n' \times OC = P \times OA + W \times AG \qquad \ldots(i)$$

where $OB = OC \cos 30°$

$$\therefore \quad OC = \frac{OB}{\cos 30^\circ} = \frac{15}{\cos 30^\circ} = 17.32 \text{ cm} = 0.1732 \text{ m}$$

$$OA = OG \cos 30° = 10 \times .866 = 8.66 \text{ cm} = 0.0866 \text{ m}$$

$$AG = OG \sin 30° = 10 \times \frac{1}{2} = 5 \text{ cm} = .05 \text{ m}$$

Substituting these values in equation (*i*), we get

$$0.2717\ V^2 \times .1732 = 11.775 \times .0866 + 58.86 \times 0.05 = 3.962$$

$$\therefore \quad V = \sqrt{\frac{3.962}{0.2717 \times .1732}} = 9.175 \text{ m/s.}$$

Problem 17.10 *A jet of water of diameter 25 mm strikes a 20 cm ×20 cm square plate of uniform thickness with a velocity of 10 m/s at the centre of the plate which is suspended vertically by a hinge on its top horizontal edge. The weight of the plate is 98.1 N. The jet strikes normal to the plate. What force must be applied at the lower edge of the plate so that plate is kept vertical ? If the plate is allowed to deflect freely, what will be the inclination of the plate with vertical due to the force exerted by jet of water?*

Solution. Given :

Diameter of the jet, $d = 25 \text{ mm} = 25 \times 10^{-3} \text{ m} = .025 \text{ m}$

$\therefore$ Area, $a = \frac{\pi}{4} (.025)^2 = .00049 \text{ m}^2$

Size of the plate, $= 20 \text{ cm} \times 20 \text{ cm}$

Weight of the plate, $W = 98.1 \text{ N}$

Velocity of jet, $V = 10 \text{ m/s}$

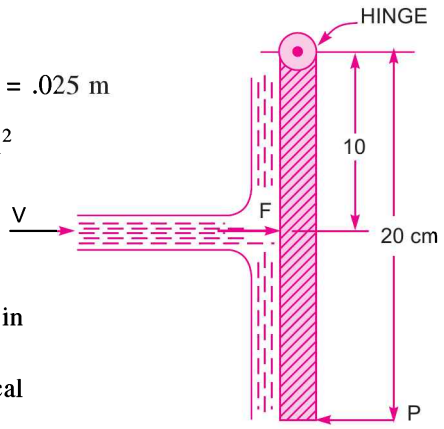

Fig. 17.9 (*a*)

(*i*) Let the force applied at the lower edge to keep the plate in vertical position is = P . See Fig.17.9 (*a*).

Force exerted by the jet of water at the centre of the vertical plate,

$$F = \rho a V^2$$
$$= 1000 \times .00049 \times 10^2 = 49 \text{ N.}$$

This force is acting at a distance of $\frac{20}{2} = 10$ cm from the hinge. The force P is acting at a distance of 20 cm from the hinge.

Taking moments about hinge,

$$F \times 10 = P \times 20$$

$$\therefore \quad 49 \times 10 = P \times 20$$

$$\therefore \quad P = \frac{49 \times 10}{20} = \mathbf{24.5 \text{ N. Ans.}}$$

(*ii*) When the plate is allowed to deflect freely about hinge.

Let the inclination of the plate with vertical = θ

In this position, the angle between the plate and jet will be

$$= (90° - \theta) .$$

$\therefore$ Force exerted by water normal to the plate is given by equation (17.2) as

$$F_n = \rho a V^2 \sin (90° - \theta) = \rho a V^2 \cos \theta$$

The distance $OB = \frac{OA}{\cos\theta} = \frac{10}{\cos\theta}$

The weight W of the plate is acting at a distance 10 cm from hinge. Distance

$$DG = OG \sin\theta = 10 \times \sin\theta$$

Taking moments about hinge, we get

$$F_n \times OB = W \times GD$$

or $$\rho a V^2 \cos\theta \times \frac{10}{\cos\theta} = W \times 10 \times \sin\theta$$

$\therefore$ $$\rho a V^2 = W \times \sin\theta$$

$\therefore$ $$\sin\theta = \frac{\rho a V^2}{W} = 1000 \times \frac{.00049 \times 10^2}{98.1} = 0.5$$

$\therefore$ $\theta = \mathbf{30°}$. **Ans.**

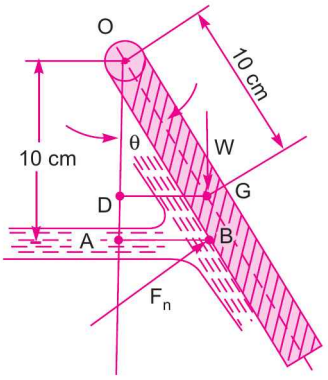

Fig. 17.9. (*b*)

Problem 17.10 (A) *A square plate of uniform thickness and length of side 300 mm hangs vertically from hinge at its top edge. When a horizontal water jet strikes the plate at its centre, the plate is deflected and comes to rest at angle of 30° to the vertical. The jet is 25 mm in diameter and has a velocity of 6 m/s. Determine the weight of the plate.*

Solution. Given :

Length of plate, $L = 300$ mm $= 0.3$ m

Angle of swing, or angle made by deflected plate with the vertical, $\theta = 30°$

Dia. of the jet, $d = 25$ mm $= 0.025$ m

$\therefore$ Area of jet, $a = \frac{\pi}{4} d^2 = \frac{\pi}{4} (0.025^2)$ m^2

Velocity of jet, $V = 6$ m/s

Let W = Weight of plate

Using equation (17.10), we get $\sin\theta = \frac{\rho \times a \times V^2}{W}$

$\therefore$ $$W = \frac{\rho^* \times a \times V^2}{\sin\theta} = \frac{1000 \times \left(\frac{\pi}{4} \times 0.025^2\right) \times 6^2}{\sin 30°} = \mathbf{35.33\ N.\ Ans.}$$

▶ 17.4 FORCE EXERTED BY A JET ON MOVING PLATES

The following cases of the moving plates will be considered :

1. Flat vertical plate moving in the direction of the jet and away from the jet,
2. Inclined plate moving in the direction of the jet, and
3. Curved plate moving in the direction of the jet or in the horizontal direction.

* If $\rho = 1000$ kg/m^3, then weight W will be in Newton.

17.4.1 Force on Flat Vertical Plate Moving in the Direction of Jet. Fig. 17.10 shows a jet of water striking a flat vertical plate moving with a uniform velocity away from the jet.

Let V = Velocity of the jet (absolute),
a = Area of cross-section of the jet,
u = Velocity of the flat plate.

In this case, the jet does not strike the plate with a velocity V, but it strikes with a relative velocity, which is equal to the absolute velocity of jet of water minus the velocity of the plate.

Hence relative velocity of the jet with respect to plate

$= (V - u)$

Mass of water striking the plate per sec

$= \rho \times$ Area of jet $\times$ Velocity with which jet strikes the plate

$= \rho a \times [V - u]$

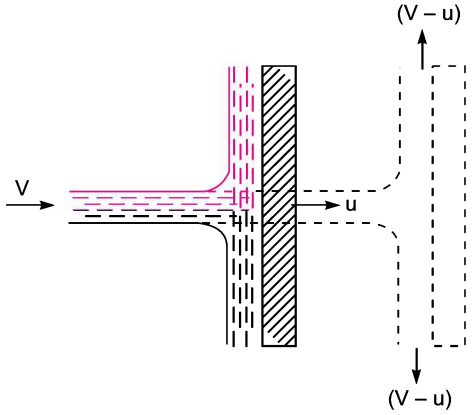

Fig. 17.10 *Jet striking a flat vertical moving plate.*

$\therefore$ Force exerted by the jet on the moving plate in the direction of the jet,

F_x = Mass of water striking per sec $\times$ [Initial velocity with which water strikes – Final velocity]

$= \rho a(V - u)\,[(V - u) - 0]$ ($\because$ Final velocity in the direction of jet is zero)

$= \rho a(V - u)^2$ ...(17.11)

In this case, the work will be done by the jet on the plate, as plate is moving. For the stationary plates, the work done is zero.

$\therefore$ Work done per second by the jet on the plate

$$= \text{Force} \times \frac{\text{Distance in the direction of force.}}{\text{Time}}$$

$= F_x \times u = \rho a(V - u)^2 \times u$ ...(17.12)

In equation (17.12), if the value of ρ for water is taken in S.I. units (*i.e.,* 1000 kg/m^3), the work done will be in N m/s. The term $\frac{\text{'Nm'}}{\text{s}}$ is equal to W (watt).

17.4.2 Force on the Inclined Plate Moving in the Direction of the Jet. Let a jet of water strikes an inclined plate, which is moving with a uniform velocity in the direction of the jet as shown in Fig. 17.11.

Let V = Absolute velocity of jet of water,
u = Velocity of the plate in the direction of jet,
a = Cross-sectional area of jet, and
θ = Angle between jet and plate.

Relative velocity of jet of water = $(V - u)$

$\therefore$ The velocity with which jet strikes = $(V - u)$

Mass of water striking per second

$= \rho \times a \times (V - u)$

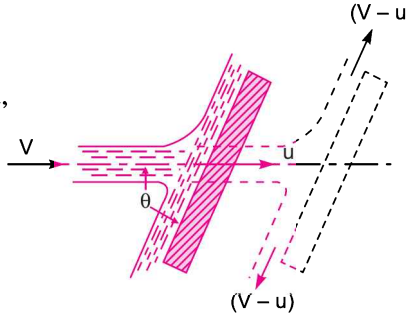

Fig. 17.11 *Jet striking an inclined moving plate.*

If the plate is smooth and loss of energy due to impact of the jet is assumed zero, the jet of water will leave the inclined plate with a velocity equal to $(V - u)$.

The force exerted by the jet of water on the plate in the direction normal to the plate is given as

F_n = Mass striking per second × [Initial velocity in the normal direction with which jet strikes – Final velocity]

$$= \rho a\,(V - u)\,[(V - u)\sin\theta - 0] = \rho a\,(V - u)^2 \sin\theta \qquad ...(17.13)$$

This normal force F_n is resolved into two components namely F_x and F_y in the direction of the jet and perpendicular to the direction of the jet respectively.

$$\therefore \qquad F_x = F_n \sin\theta = \rho a\,(V - u)^2 \sin^2\theta \qquad ...(17.14)$$

$$F_y = F_n \cos\theta = \rho a\,(V - u)^2 \sin\theta \cos\theta \qquad ...(17.15)$$

$\therefore$ Work done per second by the jet on the plate

$= F_x \times$ Distance per second in the direction of x

$$= F_x \times u = \rho a(V - u)^2 \sin^2\theta \times u = \rho a\,(V - u)^2\, u \sin^2\theta \text{ N m/s.} \qquad ...(17.16)$$

Problem 17.11 *A jet of water of diameter 10 cm strikes a flat plate normally with a velocity of 15 m/s. The plate is moving with a velocity of 6 m/s in the direction of the jet and away from the jet. Find:*

(i) the force exerted by the jet on the plate

(ii) work done by the jet on the plate per second.

Solution. Given :

Diameter of the jet, $d = 10 \text{ cm} = 0.1 \text{ m}$

$\therefore$ Area, $a = \dfrac{\pi}{4} d^2 = \dfrac{\pi}{4} (.1)^2 = .007854 \text{ m}^2$

Velocity of jet, $V = 15$ m/s

Velocity of the plate, $u = 6$ m/s.

(*i*) The force exerted by the jet on a moving flat vertical plate is given by equation (17.11),

$$F_x = \rho a\,(V - u)^2$$

$$= 1000 \times .007854 \times (15 - 6)^2 \text{ N} = \mathbf{636.17\ N.\ Ans.}$$

(*ii*) Work done per second by the jet

$$= F_x \times u = 636.17 \times 6 = \mathbf{3817.02\ Nm/s.\ Ans.}$$

Problem 17.12 *For Problem 17.11, find the power and efficiency of the jet.*

Solution. The given data from Problem 17.11 is

$$a = .007854 \text{ m}^2,\ V = 15 \text{ m/s},\ u = 6 \text{ m/s}$$

Also work done per second by the jet = 3817.02 Nm/s

(*i*) Power of the jet in kW $= \dfrac{\text{Work done per second}}{1000} = \dfrac{3817.02}{1000} = \mathbf{3.817\ kW.\ Ans.}$

(*ii*) Efficiency of the jet (η) $= \dfrac{\text{Output of the jet per second}}{\text{Input of the jet per second}}$ ...(*i*)

where output of jet/sec = Work done by jet per second = 3817.02 Nm/s

And input per second = Kinetic energy of the jet/sec

$$= \frac{1}{2}\left(\frac{\text{mass}}{\text{sec}}\right) V^2 = \frac{1}{2}(\rho a V) \times V^2 = \frac{1}{2}\rho a\, V^3$$

$$= \frac{1}{2} \times 1000 \times .007854 \times 15^3 \text{ Nm/s} = 13253.6 \text{ Nm/s}$$

$\therefore$ η of the jet $= \dfrac{3817.02}{13253.6} = 0.288 =$ **28.8%. Ans.**

Problem 17.12 (A) *A nozzle of 50 mm diameter delivers a stream of water at 20 m/s perpendicular to a plate that moves away from the jet at 5 m/s. Find :*

(i) the force on the plate,

(ii) the work done, and

(iii) the efficiency of jet. (J.N.T.U., Hyderabad S 2002)

Solution. Given :

Dia. of jet = 50 mm = 0.05 m

$\therefore$ Area, $a = \dfrac{\pi}{4}(0.05^2) = 0.0019635 \text{ m}^2$

Velocity of jet, $V = 20$ m/s, Velocity of plate, $u = 5$ m/s

(*i*) The force on the plate is given by equation (17.11) as,

$$F_x = \rho a\,(V - u)^2$$

$$= 1000 \times 0.0019635 \times (20 - 5)^2 = \textbf{441.78 N. Ans.}$$

(*ii*) The work done by the jet

$$= F_x \times u = 441.78 \times 5 = \textbf{2208.9 Nm/s. Ans.}$$

(*iii*) The efficiency of the jet, $\eta = \dfrac{\text{Output of jet}}{\text{Input of jet}}$

$$= \frac{\text{Work done/s}}{\text{K.E. of jet/s}} = \frac{F_x \times u}{\frac{1}{2} m V^2}$$

$$= \frac{F_x \times u}{\frac{1}{2}(\rho A V) \times V^2}$$

$$= \frac{2208.9}{\frac{1}{2}(1000 \times 0.0019635 \times 20) \times 20^2} = \frac{2208.9}{6540}$$

$$= 0.3377 = \textbf{33.77\%. Ans.}$$

Problem 17.13 *A 7.5 cm diameter jet having a velocity of 30 m/s strikes a flat plate, the normal of which is inclined at 45° to the axis of the jet. Find the normal pressure on the plate : (i) when the plate is stationary , and (ii) when the plate is moving with a velocity of 15 m/s and away from the jet. Also determine the power and efficiency of the jet when the plate is moving.*

Solution. Given :

Diameter of the jet, $d = 7.5 \text{ cm} = 0.075 \text{ m}$

$\therefore$ Area, $a = \frac{\pi}{4} (.075)^2 = .004417 \text{ m}^2$

Angle between the jet and plate $\theta = 90° - 45° = 45°$

Velocity of jet, $V = 30$ m/s.

(*i*) When the plate is stationary, the normal force on the plate is given by equation (17.2) as

$$F_n = \rho a V^2 \sin \theta = 1000 \times .004417 \times 30^2 \times \sin 45° = \textbf{2810.96 N. Ans.}$$

(*ii*) When the plate is moving with a velocity 15 m/s and away from the jet, the normal force on the plate is given by equation (17.13) as

$$F_n = \rho a (V - u)^2 \sin \theta \qquad \text{where } u = 15 \text{ m/s.}$$
$$= 1000 \times .004417 \times (30 - 15)^2 \times \sin 45° = \textbf{702.74 N. Ans.}$$

(*iii*) The power and efficiency of the jet when plate is moving is obtained as

Work done per second by the jet

= Force in the direction of jet × Distance moved by the plate in the direction of jet/sec

= $F_x \times u$, where $F_x = F_n \sin \theta = 702.74 \times \sin 45° = 496.9$ N

Work done/sec = $496.9 \times 15 = 7453.5$ Nm/s

$\therefore$ $$\text{Power in kW} = \frac{\text{Work done per second}}{1000} = \frac{7453.5}{1000} = \textbf{7.453 kW. Ans.}$$

$$\text{Efficiency of the jet} = \frac{\text{Output}}{\text{Input}} = \frac{\text{Work done per second}}{\text{Kinetic energy of the jet}}$$

$$= \frac{7453.5}{\frac{1}{2}(\rho a V) \times V^2} = \frac{7453.5}{\frac{1}{2}\rho a V^3} = \frac{7453.5}{\frac{1}{2} \times 1000 \times .004417 \times 30^3}$$

$$= 0.1249 \simeq 0.125 = \textbf{12.5\%. Ans.}$$

17.4.3 Force on the Curved Plate when the Plate is Moving in the Direction of Jet. Let a jet of water strikes a curved plate at the centre of the plate which is moving with a uniform velocity in the direction of the jet as shown in Fig. 17.12.

Let V = Absolute velocity of jet,

a = Area of jet,

u = Velocity of the plate in the direction of the jet.

Relative velocity of the jet of water or the velocity with which jet strikes the curved plate = $(V - u)$.

If plate is smooth and the loss of energy due to impact of jet is zero, then the velocity with which the jet will be leaving the curved vane = $(V - u)$.

This velocity can be resolved into two components, one in the direction of the jet and other perpendicular to the direction of the jet.

Component of the velocity in the direction of jet

$$= -(V - u) \cos \theta$$

(–ve sign is taken as at the outlet, the component is in the opposite direction of the jet).

Component of the velocity in the direction perpendicular to the direction of the jet = $(V - u) \sin \theta$.

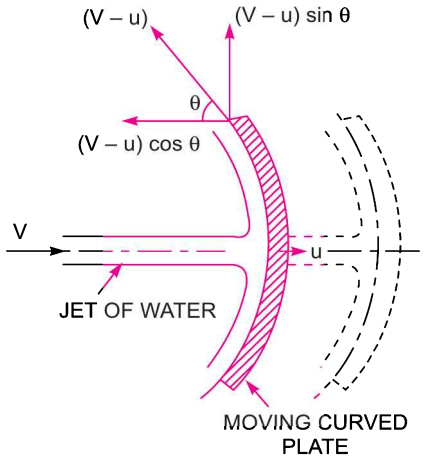

Fig. 17.12 *Jet striking a curved moving plate.*

Mass of the water striking the plate = $\rho \times a \times$ Velocity with which jet strikes the plate

$= \rho a(V - u)$

$\therefore$ Force exerted by the jet of water on the curved plate in the direction of the jet,

F_x = Mass striking per sec × [Initial velocity with which jet strikes the plate in the direction of jet – Final velocity]

$= \rho a(V - u)\ [(V - u) - (-(V - u) \cos \theta)]$

$= \rho a(V - u)\ [(V - u) + (V - u) \cos \theta]$

$= \rho a(V - u)^2\ [1 + \cos \theta]$ ...(17.17)

Work done by the jet on the plate per second

$= F_x \times$ Distance travelled per second in the direction of x

$= F_x \times u = \rho a(V - u)^2\ [1 + \cos \theta] \times u$

$= \rho a(V - u)^2 \times u\ [1 + \cos \theta]$ ...(17.18)

Problem 17.14 *A jet of water of diameter 7.5 cm strikes a curved plate at its centre with a velocity of 20 m/s. The curved plate is moving with a velocity of 8 m/s in the direction of the jet. The jet is deflected through an angle of 165°. Assuming the plate smooth find :*

(i) Force exerted on the plate in the direction of jet, (ii) Power of the jet, and (iii) Efficiency of the jet.

Solution. Given :

Diameter of the jet, $d = 7.5$ cm $= 0.075$ m

$\therefore$ Area, $a = \frac{\pi}{4}(.075)^2 = 0.004417$

Velocity of the jet, $V = 20$ m/s

Velocity of the plate, $u = 8$ m/s

Angle of deflection of the jet, $= 165°$

$\therefore$ Angle made by the relative velocity at the outlet of the plate,

$\theta = 180° - 165° = 15°$.

(*i*) Force exerted by the jet on the plate in the direction of the jet is given by equation (17.17) as

$= F_x = \rho a(V - u)^2\ (1 + \cos \theta)$

$= 1000 \times .004417 \times (20 - 8)^2\ [1 + \cos 15°] =$ **1250.38 N. Ans.**

(*ii*) Work done by the jet on the plate per second

$= F_x \times u = 1250.38 \times 8 = 10003.04$ N m/s

$\therefore$ Power of the jet $= \frac{10003.04}{1000} =$ **10 kW. Ans.**

(*iii*) Efficiency of the jet $= \frac{\text{Output}}{\text{Input}} = \frac{\text{Work done by jet/sec}}{\text{Kinetic energy of jet/sec}}$

$= \frac{1250.38 \times 8}{\frac{1}{2}(\rho a V) \times V^2} = \frac{1250.38 \times 8}{\frac{1}{2} \times 1000 \times .004417 \times V^3}$

$= \frac{1250.38 \times 8}{\frac{1}{2} \times 1000 \times .004417 \times 20^3} = 0.564 =$ **56.4%. Ans**

Problem 17.15 *A jet of water from a nozzle is deflected through 60° from its original direction by a curved plate which it enters tangentially without shock with a velocity of 30 m/s and leaves with a mean velocity of 25 m/s. If the discharge from the nozzle is 0.8 kg/s, calculate the magnitude and direction of the resultant force on the vane, if the vane is stationary.*

Solution. Given :

Velocity at inlet, $V_1 = 30$ m/s

Velocity at outlet, $V_2 = 25$ m/s

Mass per second $= 0.8$ kg/s

Force in the direction of jet,

$$F_x = \text{Mass per second} \times (V_{1x} - V_{2x})$$

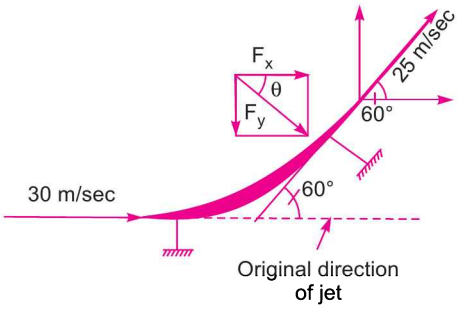

Fig. 17.13 (*a*)

where V_{1x} = Initial velocity in the direction of x

$= 30$ m/s

V_{2x} = Final velocity in the direction of x

$$= 25 \cos 60^\circ = 25 \times \frac{1}{2} = 12.5 \text{ m/s}$$

$$\therefore \quad F_x = 0.8[30 - 12.5] = 0.8 \times 17.5 = 14.0 \text{ N}$$

Similarly, force normal to the jet,

$$F_y = \text{Mass per second} \times (V_{1y} - V_{2y})$$

$$= 0.8\ [0 - 25 \sin 60^\circ] = -17.32 \text{ N}$$

–ve sign means the force, F_y, is acting in the vertically downward direction.

$\therefore$ Resultant force on the vane $= \sqrt{F_x^2 + F_y^2} = \sqrt{14^2 + (-17.32)^2} =$ **22.27 N. Ans.**

The angle made by the resultant with x-axis

$$\tan \theta = \frac{F_y}{F_x} = \frac{-17.32}{14.0} = -1.237$$

–ve sign means the angle θ is in the clockwise direction with x- axis as shown in Fig. 17.13 (*a*)

$$\therefore \quad \theta = \tan^{-1} 1.237 = \mathbf{51^\circ\ 2.86'.\ Ans.}$$

Problem 17.16 (*a*) *A stationary vane having an inlet angle of zero degree and an outlet angle of 25° as shown in Fig. 17.13(b), receives water at a velocity of 50 m/s. Determine the components of force acting on it in the direction of the jet velocity and normal to it. Also find the resultant force in magnitude and direction per unit weight of the flow.*

(b) If the vane stated above is moving with a velocity of 20 m/s in the direction of the jet, calculate the force components in the direction of the vane velocity and across it, also the resultant force in magnitude and direction. Calculate the work done and power developed per unit weight of the flow.

Solution. Given :

(*a*) Velocity of jet, $V = 50$ m/s

Angle at outlet, $= 25^\circ$

For the stationary vane, the force in the direction of jet is given as

$$F_x = \text{Mass per sec} \times [V_{1x} - V_{2x}]$$

where $V_{1x} = 50$ m/s

$V_{2x} = -50 \cos 25^\circ = -45.315$

∴ Force in the direction of jet per unit weight of water

$$= \frac{\text{Mass/sec}\,[50 - (-45.315)]}{\text{Weight of water/sec}}$$

or
$$F_x = \frac{(\text{Mass/sec})\,[50 + 45.315]}{(\text{Mass/sec}) \times g}$$

$$= \frac{1}{g}\,[50 + 45.315]\ \text{N/N} = \frac{95.315}{9.81} = 9.716\ \text{N/N}$$

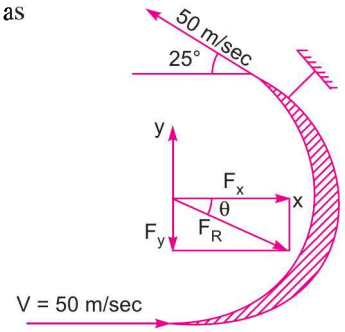

Fig. 17.13 (*b*)

Force exerted by jet in the direction perpendicular to the direction of the jet per unit weight of the flow,

$$F_y = \frac{(\text{Mass per sec})\,[V_{1y} - V_{2y}]}{g \times \text{Mass per sec}}$$

$$= \frac{1}{g}\,[V_{1y} - V_{2y}] = \frac{1}{g}\,[0 - 50 \sin 25^\circ] \quad (\because V_{1y} = 0,\ V_{2y} = 50 \sin 25^\circ)$$

$$= \frac{-50 \sin 25^\circ}{9.81} = \mathbf{-\ 2.154.\ Ans.}$$

–ve sign means the force F_y is acting in the downward direction.

∴ Resultant force per unit weight of water = $\sqrt{F_x^2 + F_y^2}$

or
$$\mathbf{F_R} = \sqrt{(9.716)^2 + (2.154)^2} = \mathbf{9.952\ N.\ Ans.}$$

The angle made by the resultant with the x-axis,

$$\tan\theta = \frac{F_y}{F_x} = \frac{2.154}{9.716} = 0.2217$$

∴ $\theta = \tan^{-1} .2217 = \mathbf{12.50^\circ.\ Ans.}$

(*b*) Velocity of the vane = 20 m/s.

When the vane is moving in the direction of the jet, the force exerted by the jet on the plate in the direction of jet,

F_x' = [Mass of water striking/sec] × $[V_{1x} - V_{2x}]$

where V_{1x} = Initial velocity of the striking water

$= (V - u) = 50 - 20 = 30$ m/s

V_{2x} = Final velocity in the direction of x

$= -(V - u) \cos 25^\circ = 30 \times \cos 25^\circ = -27.189$ m/s.

∴ F_x = Mass per sec [30 + 27.189]

Force in the direction of jet per unit weight,

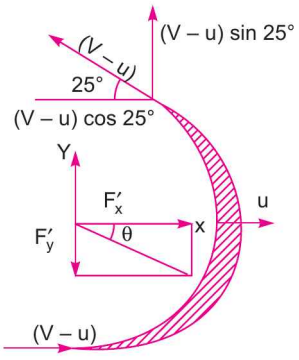

Fig. 17.14

$$F_x' = \frac{\text{Mass per sec } [30 + 27.189]}{\text{Mass per sec} \times g}$$

$$= \frac{(30 + 27.189)}{9.81} = 5.829 \text{ N.}$$

Force exerted by the jet in the direction perpendicular to direction of jet, per unit weight,

$$F_y' = \frac{1}{g} [V_{1y} - V_{2y}]$$

where $V_{1y} = 0$; $V_{2y} = (V - u) \sin 25^\circ = (50 - 20) \sin 25^\circ = 30 \sin 25^\circ$

$$F_y' = \frac{1}{9.81} [0 - 30 \sin 25^\circ] = -1.292 \text{ N}$$

$\therefore$ Resultant force $= \sqrt{(5.829)^2 + (1.292)^2} = 5.917$ N

The angle made by the resultant with x-axis, $\tan \theta = \frac{1.292}{5.829} = 0.2217$

$\therefore$ $\theta = \tan^{-1} .2217 = 12.30^\circ$

$\therefore$ Work done per second per unit weight of flow

$= F_x' \times u = 5.829 \times 20 = 116.58$ N m/s

$\therefore$ Power developed $= \frac{\text{Work done per second}}{1000} = \frac{116.58}{1000} =$ **0.116 kW. Ans.**

Problem 17.17 *A jet of water of diameter 50 mm moving with a velocity of 25 m/s impinges on a fixed curved plate tangentially at one end at an angle of 30° to the horizontal. Calculate the resultant force of the jet on the plate if the jet is deflected through an angle of 50°. Take g = 10 m/s²*

Solution. Given :

Dia. of jet, $d = 50$ mm $= 0.05$ m

$\therefore$ Area of jet, $a = \frac{\pi}{4} (0.05)^2 \text{m}^2$

Velocity of jet, $V = 25$ m/s

The angle made by the jet at inlet with horizontal, $\theta = 30^\circ$

Angle of deflection $= 50^\circ$

$\therefore$ Angle made by the jet at outlet with horizontal is given by,

$\phi = \theta +$ Angle of deflection

$= 30^\circ + 50^\circ = 80^\circ$

Value of g $= 10$ m/s²

The force exerted by the jet of water in the direction of x is given by,

$$F_x = \rho a V [V_{1x} - V_{2x}] \qquad ...(i)$$

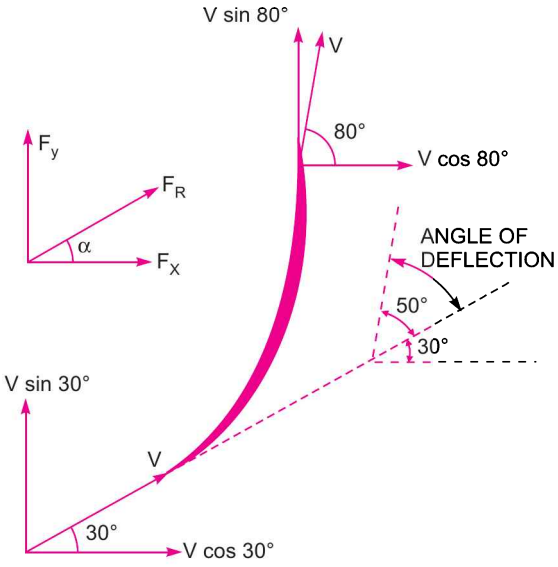

Fig. 17.14 (*a*)

where $\rho = 1000$ ($\because$ g is given as 10 m/s^2)

$$a = \frac{\pi}{4}(0.05)^2;\ V = 25 \text{ m/s};$$

$$V_{1x} = V \cos 30° = 25 \cos 30°,$$

$$V_{2x} = V \cos 80° = 25 \cos 80°.$$

Substituting these values in equation (i), we get

$$F_x = 1000 \times \frac{\pi}{4}(0.05)^2 \times 25\,[25 \cos 30° - 25 \cos 80°] = 849.7 \text{ N}$$

The force in the direction of y is given by,

$$F_y = \rho a V[V_{1y} - V_{2y}]$$

$$= 1000 \times \frac{\pi}{4}(0.05)^2 \times 25[25 \sin 30° - 25 \sin 80°] = -594.9 \text{ N}$$

The –ve sign shows that force F_y is acting in the downward direction.

The resultant force is given by,

$$F_R = \sqrt{F_x^2 + F_y^2}$$

$$= \sqrt{849.7^2 + 594.9^2} = \mathbf{1037\ N.\ Ans.}$$

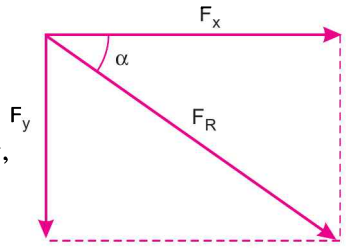

Fig. 17.14 (b)

And the angle made by the resultant with the horizontal is given by,

$$\tan \alpha = \frac{F_y}{F_x} = \frac{594.9}{849.7} = 0.7$$

$$\therefore \quad \alpha = \tan^{-1} 0.7 = \mathbf{35°.}\ \mathbf{Ans.}$$

17.4.4 Force Exerted by a Jet of Water on an Unsymmetrical Moving Curved Plate when Jet Strikes Tangentially at one of the Tips. Fig. 17.15 shows a jet of water striking a moving curved plate (also called vane) tangentially, at one of its tips. As the jet strikes tangentially, the loss of energy due to impact of the jet will be zero. In this case as plate is moving, the velocity with which jet of water strikes is equal to the relative velocity of the jet with respect to the plate. Also as the plate is moving in different direction of the jet, the relative velocity at inlet will be equal to the vector difference of the velocity of jet and velocity of the plate at inlet.

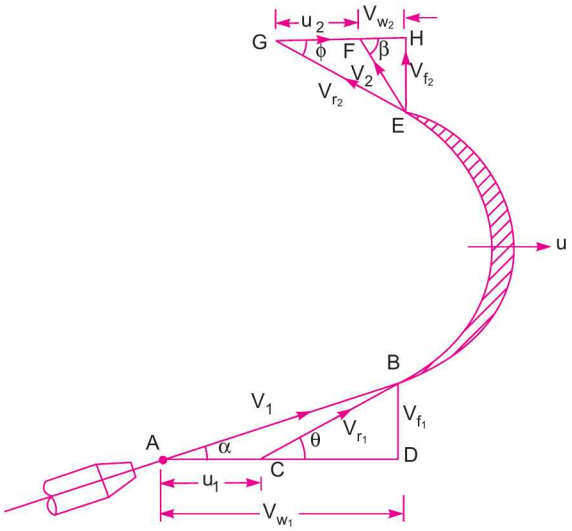

Fig. 17.15 *Jet striking a moving curved vane at one of the tips.*

Let V_1 = Velocity of the jet at inlet.

u_1 = Velocity of the plate (vane) at inlet.

V_{r_1} = Relative velocity of jet and plate at inlet.

α = Angle between the direction of the jet and direction of motion of the plate, also called guide blade angle.

θ = Angle made by the relative velocity (V_{r_2}) with the direction of motion at inlet also called vane angle at inlet.

V_{w_1} and V_{f_1} = The components of the velocity of the jet V_1, in the direction of motion and perpendicular to the direction of motion of the vane respectively.

V_{w_1} = It is also known as velocity of whirl at inlet.

V_{f_1} = It is also known as velocity of flow at inlet.

V_2 = Velocity of the jet, leaving the vane or velocity of jet at outlet of the vane.

u_2 = Velocity of the vane at outlet.

V_{r_2} = Relative velocity of the jet with respect to the vane at outlet.

β = Angle made by the velocity V_2 with the direction of motion of the vane at outlet.

ϕ = Angle made by the relative velocity V_{r_2} with the direction of motion of the vane at outlet and also called vane angle at outlet.

V_{w_1} and V_{f_1} = Components of the velocity V_2, in the direction of motion of vane and perpendicular to the direction of motion of vane at outlet.

V_{w_2} = It is also called the velocity of whirl at outlet.

V_{f_2} = Velocity of flow at outlet.

The triangles *ABD* and *EGH* are called the velocity triangles at inlet and outlet. These velocity triangles are drawn as given below :

1. Velocity Triangle at Inlet. Take any point *A* and draw a line $AB = V_1$ in magnitude and direction which means line *AB* makes an angle α with the horizontal line *AD*. Next draw a line $AC = u_1$ in magnitude. Join *C* to *B*. Then *CB* represents the relative velocity of the jet at inlet. If the loss of energy at inlet due to impact is zero, then *CB* must be in the tangential direction to the vane at inlet. From *B* draw a vertical line *BD* in the downward direction to meet the horizontal line *AC* produced at *D*.

Then BD = Represents the velocity of flow at inlet = V_{f_1}

AD = Represents the velocity of whirl at inlet = V_{w_1}

$\angle BCD$ = Vane angle at inlet = θ.

2. Velocity Triangle at Outlet. If the vane surface is assumed to be very smooth, the loss of energy due to friction will be zero. The water will be gliding over the surface of the vane with a relative velocity equal to V_{r_1} and will come out of the vane with a relative relocity V_{r_2}. This means that the relative velocity at outlet $V_{r_2} = V_{r_1}$. And also the relative velocity at outlet should be in tangential direction to the vane at outlet.

Draw *EG* in the tangential direction of the vane at outlet and cut $EG = V_{r_2}$. From *G*, draw a line *GF* in the direction of vane at outlet and equal to u_2, the velocity of the vane at outlet. Join *EF*. Then *EF* represents the absolute velocity of the jet at outlet in magnitude and direction. From *E* draw a vertical line *EH* to meet the line *GF* produced at *H*. Then

EH = Velocity of flow at outlet = V_{f_2}

FH = Velocity of whirl at outlet = V_{w_2}

ϕ = Angle of vane at outlet.

β = Angle made by V_2 with the direction of motion of vane at outlet.

If the vane is smooth and is having velocity in the direction of motion at inlet and outlet equal then we have

$u_1 = u_2 = u$ = Velocity of vane in the direction of motion and

$V_{r_1} = V_{r_2}$.

Now mass of water striking vane per sec = $\rho a V_{r_1}$ ...(*i*)

where a = Area of jet of water, V_{r_1} = Relative velocity at inlet.

∴ Force exerted by the jet in the direction of motion

F_x = Mass of water striking per sec × [Initial velocity with which jet strikes in the direction of motion – Final velocity of jet in the direction of motion] ...(*ii*)

But initial velocity with which jet strikes the vane = V_{r_1}

The component of this velocity in the direction of motion

$= V_{r_1} \cos\theta = (V_{w_1} - u_1)$ (See Fig. 17.15)

Similarly, the component of the relative velocity at outlet in the direction of motion = $- V_{r_2} \cos\phi$

$= - [u_2 + V_{w_2}]$

–ve sign is taken as the component of V_{r_2} in the direction of motion is in the opposite direction.

Substituting the equation (*i*) and all above values of the velocities in equation (*ii*), we get

$$F_x = \rho a V_{r_1} [(V_{w_1} - u_1) - \{ - (u_2 + V_{w_2})\}] = \rho a V_{r_1} [V_{w_1} - u_1 + u_2 + V_{w_2}]$$

$$= \rho a V_{r_1} [V_{w_1} + V_{w_2}] \quad (\because \ u_1 = u_2) \quad ...(iii)$$

Equation (*iii*) is true only when angle β shown in Fig. 17.15 is an acute angle. If $\beta = 90°$, the $V_{w_2} = 0$, then equation (*iii*) becomes as,

$$F_x = \rho a V_{r_1} [V_{w_1}]$$

If β is an obtuse angle, the expression for F_x will become

$$F_x = \rho a V_{r_1} [V_{w_1} - V_{w_2}]$$

Thus in general, F_x is written as $F_x = \rho a V_{r_1} [V_{w_1} \pm V_{w_2}]$ ...(17.19)

Work done per second on the vane by the jet

= Force × Distance per second in the direction of force

$= F_x \times u = \rho a V_{r_1} [V_{w_1} \pm V_{w_2}] \times u$ ...(17.20)

∴ Work done per second per unit weight of fluid striking per second

$$= \frac{\rho a V_{r_1} \left[V_{w_1} \pm V_{w_2}\right] \times u}{\text{Weight of fluid striking/s}} \frac{\text{Nm/s}}{\text{N/s}} = \frac{\rho a V_{r_1} \left[V_{w_1} \pm V_{w_2}\right] \times u}{g \times \rho a V_{r_1}} = \text{Nm/N}$$

$$= \frac{1}{g} [V_{w_1} \pm V_{w_2}] \times u \text{ Nm/N} \quad ...(17.21)$$

Work done/sec per unit mass of fluid striking per second

$$= \frac{\rho a V_{r_1}\left[V_{w_1} \pm V_{w_2}\right] \times u}{\text{Mass of fluid striking / s}} \frac{\text{Nm / s}}{\text{kg / s}} = \frac{\rho a V_{r_1}\left[V_{w_1} \pm V_{w_2}\right] \times u}{\rho a V_{r_1}} \text{ Nm/kg}$$

$$= (V_{w_1} \pm V_{w_2}) \times u \text{ Nm/kg} \qquad ...[17.21(A)]$$

Note. Equation (17.21) gives the work done per unit weight whereas equation [17.21(*A*)] gives the work done per unit mass.

3. Efficiency of Jet. The work done by the jet on the vane given by equation (17.20), is the output of the jet whereas the initial kinetic energy of the jet is the input. Hence, the efficiency (η) of the jet is expressed as

$$\eta = \frac{\text{Output}}{\text{Input}} = \frac{\text{Work done per second on the vane}}{\text{Initial K. E. per second of the jet}} = \frac{\rho a V_{r_1}(V_{w_1} \pm V_{w_2}) \times u}{\frac{1}{2} m V_1^2}$$

where m = mass of the fluid per second in the jet = $\rho a V_1$

V_1 = initial velocity of jet

$$\therefore \qquad \eta = \frac{\rho a V_{r_1}\left[V_{w_1} \pm V_{w_2}\right] \times u}{\frac{1}{2}(\rho a V_1) \times V_1^2}. \qquad ...[17.21(B)]$$

Problem 17.18 *A jet of water having a velocity of 20 m/s strikes a curved vane, which is moving with a velocity of 10 m/s. The jet makes an angle of 20° with the direction of motion of vane at inlet and leaves at an angle of 130° to the direction of motion of vane an outlet. Calculate :*

(i) Vane angles, so that the water enters and leaves the vane without shock.

(ii) Work done per second per unit weight of water striking (or work done per unit weight of water striking) the vane per second.

Solution. Given :

Velocity of jet, $V_1 = 20$ m/s

Velocity of vane, $u_1 = 10$ m/s

Angle made by jet at inlet, with direction of motion of vane, $\alpha = 20°$

Angle made by the leaving jet, with the direction of motion $= 130°$

$\therefore \quad \beta = 180° - 130° = 50°$

In this problem, $u_1 = u_2 = 10$ m/s

$V_{r_1} = V_{r_2}$

(*i*) **Vane Angle** means angle made by the relative velocities at inlet and outlet, *i.e.*, θ and ϕ.

From Fig. 17.16, in ΔABD, we have $\tan \theta = \frac{BD}{CD}$

$$= \frac{V_{f_1}}{AD - AC} = \frac{V_{f_1}}{V_{w_1} - u_1} \qquad ...(i)$$

where $V_{f_1} = V_1 \sin \alpha = 20 \times \sin 20^o = 6.84$ m/s

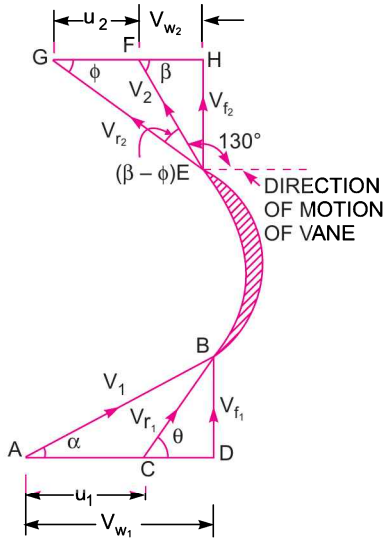

Fig. 17.16

$V_{w_1} = V_1 \cos \alpha = 20 \times \cos 20^\circ = 18.794$ m/s.

$u_1 = 10$ m/s

$$\therefore \quad \tan \theta = \frac{6.84}{18.794 - 10} = .7778 \text{ or } \theta = 37.875^\circ$$

$$\therefore \quad \theta = \mathbf{37^\circ\ 52.5'.\ Ans.}$$

From, ΔABC, $\quad \sin \theta = \dfrac{V_{f_1}}{V_{r_1}}$ or $V_{r_1} = \dfrac{V_{f_1}}{\sin \theta} = \dfrac{6.84}{\sin 37.875^\circ} = 11.14$

$$\therefore \quad V_{r_2} = V_{r_1} = 11.14 \text{ m/s.}$$

From, ΔEFG, applying sine rule, we have

$$\frac{V_{r_2}}{\sin (180^\circ - \beta)} = \frac{u_2}{\sin (\beta - \phi)}$$

or $$\frac{11.14}{\sin \beta} = \frac{10}{\sin [\beta - \phi]} \quad \text{or} \quad \frac{11.14}{\sin 50^\circ} = \frac{10}{\sin [50^\circ - \phi]} \qquad (\because \ \beta = 50^\circ)$$

$$\therefore \quad \sin (50^\circ - \phi) = \frac{10 \times \sin 50^\circ}{11.14} = 0.6876 = \sin 43.44^\circ$$

$$\therefore \quad 50^\circ - \phi = 43.44^\circ \quad \text{or} \quad \phi = 50^\circ - 43.44^\circ = 6.56^\circ$$

$$\therefore \quad \phi = \mathbf{6^\circ\ 33.6'.\ Ans.}$$

(*ii*) Work done per second per unit weight of the water striking the vane per second is given by equation (17.21) as

$$= \frac{1}{g} [V_{w_1} + V_{w_2}] \times u \text{ Nm/N (+ ve sign is taken as } \beta \text{ is an acute angle)}$$

where $V_{w_1} = 18.794$ m/s, $V_{w_2} = GH - GF = V_{r_2} \cos \phi - u_2 = 11.14 \times \cos 6.56^\circ - 10 = 1.067$ m/s

$u = u_1 = u_2 = 10$ m/s

$\therefore$ Work done per unit weight of water

$$= \frac{1}{9.81} [18.794 + 1.067] \times 10 \text{ Nm/N} = \mathbf{20.24\ Nm/N.\ Ans.}$$

Problem 17.19 *A jet of water having a velocity of 40 m/s strikes a curved vane, which is moving with a velocity of 20 m/s. The jet makes an angle of 30° with the direction of motion of vane at inlet and leaves at an angle of 90° to the direction of motion of vane at outlet. Draw the velocity triangles at inlet and outlet and determine the vane angles at inlet and outlet so that the water enters and leaves the vane without shock.*

Solution. Given :

Velocity of jet, $V_1 = 40$ m/s

Velocity of vane, $u_1 = 20$ m/s

Angle made by jet at inlet, $\alpha = 30^\circ$

Angle made by leaving jet $= 90^\circ$

$\therefore$ $\beta = 180^\circ - 90^\circ = 90^\circ$

For this problem, we have

$$u_1 = u_2 = u = 20 \text{ m/s}$$

Vane angles at inlet and outlet are θ and ϕ respectively.

From ΔBCD, we have

$$\tan\theta = \frac{BD}{CD} = \frac{BD}{AD - AC} = \frac{V_{f_1}}{V_{w_1} - u_1}$$

where $V_{f_1} = V_1 \sin\alpha = 40 \times \sin 30^\circ = 20$ m/s

$V_{w_1} = V_1 \cos\alpha = 40 \times \cos 30^\circ = 34.64$ m/s

$u_1 = 20$ m/s

$$\therefore \quad \tan\theta = \frac{20}{34.64 - 20} = \frac{20}{14.64} = 1.366 = \tan 53.79^\circ$$

$$\therefore \quad \theta = 53.79^\circ \quad \text{or} \quad \mathbf{53^\circ\ 47.4'.\ Ans.}$$

Also from ΔBCD,

$$\sin\theta = \frac{V_{f_1}}{V_{r_1}} \quad \text{or} \quad V_{r_1} = \frac{V_{f_1}}{\sin\theta} = \frac{20}{\sin 53.79^\circ}$$

$$\therefore \quad V_{r_1} = 24.78$$

But $V_{r_2} = V_{r_1} = 24.78$

Hence, from ΔEFG, $\cos\phi = \frac{u_2}{V_{r_2}} = \frac{20}{24.78} = 0.8071 = \cos 36.18^\circ$

$$\therefore \quad \phi = 36.18^\circ \quad \text{or} \quad \mathbf{36^\circ\ 10.8'.\ Ans.}$$

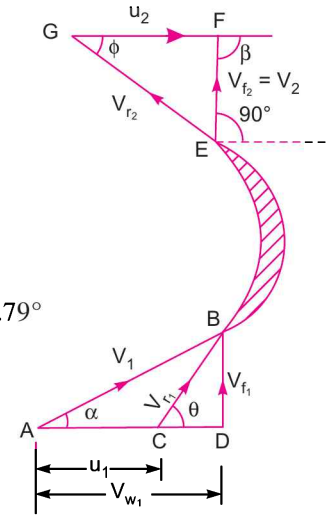

Fig. 17.17

Problem 17.20 *A jet of water of diameter 50 mm, having a velocity of 20 m/s strikes a curved vane which is moving with a velocity of 10 m/s in the direction of the jet. The jet leaves the vane at an angle of 60° to the direction of motion of vane at outlet. Determine :*

(i) The force exerted by the jet on the vane in the direction of motion.

(ii) Work done per second by the jet.

Solution. Given :

Diameter of the jet, $d = 50$ mm $= 0.05$ m

$$\therefore \quad \text{Area,} \quad a = \frac{\pi}{4}(.05)^2 = .001963 \text{ m}^2$$

Velocity of jet, $V_1 = 20$ m/s

Velocity of vane, $u_1 = 10$ m/s

As jet and vane are moving in the same direction,

$$\therefore \quad \alpha = 0$$

Angle made by the leaving jet, with the direction of motion $= 60^\circ$

$$\therefore \quad \beta = 180^\circ - 60^\circ = 120^\circ$$

For this problem, we have

$$u_1 = u_2 = u = 10 \text{ m/s}$$

$$V_{r_1} = V_{r_2}$$

From Fig. 17.18, we have

$$V_{r_1} = AB - AC = V_1 - u_1$$

$$= 20 - 10 = 10 \text{ m/s}$$

$$V_{w_1} = V_1 = 20 \text{ m/s}$$

$$\therefore \quad V_{r_2} = V_{r_1} = 10 \text{ m/s}$$

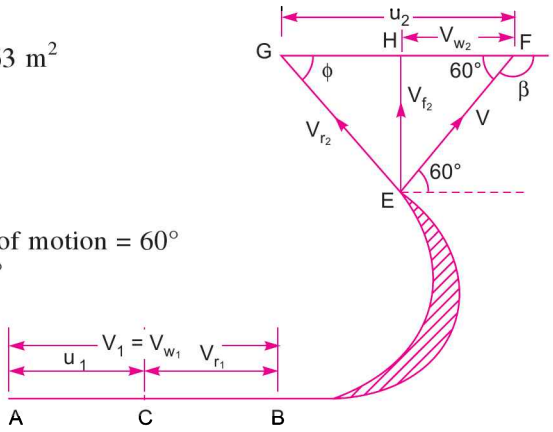

Fig. 17.18

Now in ΔEFG, $EG = V_{r_2} = 10$ m/s,

$GF = u_2 = 10$ m/s

$\angle GEF = 180^\circ - (60^\circ + \phi) = (120^\circ - \phi)$

From sine rule, we have

$$\frac{EG}{\sin 60^\circ} = \frac{GF}{\sin (120^\circ - \phi)} \quad \text{or} \quad \frac{10}{\sin 60^\circ} = \frac{10}{\sin (120^\circ - \phi)}$$

or $\sin 60^\circ = \sin (120^\circ - \phi)$

$\therefore$ $60^\circ = 120^\circ - \phi$ or $\phi = 120^\circ - 60^\circ = 60^\circ$

Now $V_{w_2} = HF = GF - GH$

$= u_2 - V_{r_2} \cos \phi = 10 - 10 \times \cos 60^\circ = 10 - 5 = 5$ m/s.

(*i*) The force exerted by the jet on the vane in the direction of motion is given by equation (17.19) as

$F_x = \rho a V_{r_1} [V_{w_1} - V_{w_2}]$ (–ve sign is taken as β is an obtuse angle)

$= 1000 \times .001963 \times 10 [20 - 5]$ N = **294.45 N. Ans.**

(*ii*) Work done per second by the jet

$= F_x \times u = 294.45 \times 10 = 2944.5$ N m/s

= **2944.5 W. Ans.** $[\because$ Nm / s = W (watt)$]$

Problem 17.21 *A jet of water having a velocity of 15 m/s strikes a curved vane which is moving with a velocity of 5 m/s. The vane is symmetrical and is so shaped that the jet is deflected through 120°. Find the angle of the jet at inlet of the vane so that there is no shock. What is the absolute velocity of the jet at outlet in magnitude and direction and the work done per unit weight of water. Assume the vane to be smooth.*

Solution. Given :

Velocity of jet, $V_1 = 15$ m/s

Velocity of vane, $u_1 = 5$ m/s

As vane is symmetrical. Hence angle $\theta = \phi$

Angle of deflection of the jet $= 120^\circ = 180^\circ - (\theta + \phi)$

$\therefore$ $\theta + \phi = 60^\circ$ or each angle, *i.e.*, $\theta = \phi = 30^\circ$

Let the angle of jet at inlet $= \alpha$

Absolute velocity of jet at outlet $= V_2$

Angle made by V_2 at outlet with direction of motion of vane $= \beta^*$.

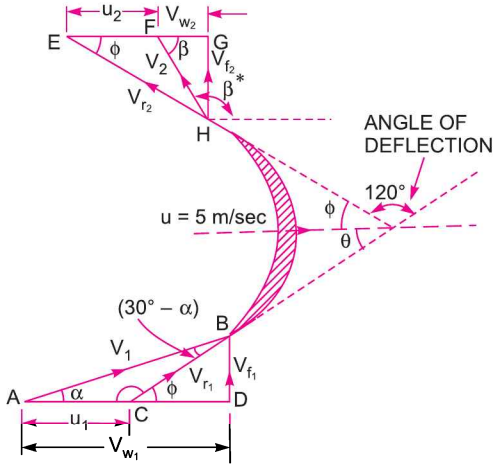

Fig. 17.19

For this problem, $u_1 = u_2 = u = 5$ m/s

$V_{r_1} = V_{r_2}$ (as vane is smooth)

Applying the sine rule to ΔACB,

$$\frac{AB}{\sin(180^\circ - \theta)} = \frac{AC}{\sin(30^\circ - \alpha)} \quad \text{or} \quad \frac{V_1}{\sin(180^\circ - 30^\circ)} = \frac{u_1}{\sin(30^\circ - \alpha)}$$

or $$\frac{15}{\sin 30^\circ} = \frac{5}{\sin(30^\circ - \alpha)} \quad \text{or} \quad \sin(30^\circ - \alpha) = \frac{5 \sin 30^\circ}{15}$$

$$= \frac{1}{3} \times 0.5 = .1667 = \sin 9.596^\circ$$

$\therefore$ $30^\circ - \alpha = 9.596^\circ$ or $\alpha = 30^\circ - 9.596^\circ = 20.404^\circ$ or **20° 24′. Ans.**

Also from sine rule to ΔACB, we have

$$\frac{AB}{\sin(180^\circ - 30^\circ)} = \frac{CB}{\sin \alpha} \quad \text{or} \quad \frac{V_1}{\sin 30^\circ} = \frac{V_{r_1}}{\sin 20.404^\circ}$$

$\therefore$ $$V_{r_1} = \frac{V_1 \sin 20.404^\circ}{\sin 30^\circ} = 10.46 \text{ m/s}$$

$\therefore$ $V_{r_2} = V_{r_1} = 10.46$ m/s

From velocity ΔHEG at outlet,

$$V_{r_2} \cos \phi = u_2 + V_{w_2} \quad \text{or} \quad 10.46 \cos 30^\circ = 5.0 + V_{w_2}$$

$\therefore$ $V_{w_2} = 10.46 \cos 30^\circ - 5.0 = 4.06$ m/s

Also, we have $V_{r_2} \sin \phi = V_{f_2}$ or $V_{f_2} = 10.46 \sin 30^\circ = 5.23$ m/s

In ΔHFG, $$V_2 = \sqrt{V_{f_2}^2 + V_{w_2}^2} = \sqrt{5.23^2 + 4.06^2}$$

$$= \sqrt{27.353 + 16.483} = \mathbf{6.62 \text{ m/s. Ans.}}$$

$$\tan \beta = \frac{V_{f_2}}{V_{w_2}} = \frac{5.23}{4.06} = 1.288 = \tan 52.17^\circ$$

$\therefore$ $\beta = 52.17^\circ$ or $52^\circ\ 10.2'$

$\therefore$ Angle made by absolute velocity at outlet with the direction of motion β^*

$$= 180^\circ - \beta = 180^\circ - (52^\circ\ 10.2') = 127^\circ\ 49.8'$$

$\therefore$ $\beta^* = \mathbf{127^\circ\ 49.8. \text{ Ans.}}$

Work done* per unit weight of the water striking

$$= \frac{1}{g} [V_{w_1} + V_{w_2}] \times u \text{ Nm } (\because \text{ + ve sign taken as } \beta \text{ is an acute angle})$$

$$= \frac{1}{9.81} [V_1 \cos \alpha + 4.06] \times 5 \qquad (\because \quad V_{w_1} = V_1 \cos \alpha)$$

$$= \frac{5}{9.81} [15 \cos 20.404^\circ + 4.06] = \mathbf{9.225 \text{ Nm/N. Ans.}}$$

---

* Work done per unit weight of water striking is the same as work done per second per unit weight of water striking per second refer to equation (17.21).

Problem 17.22 *A jet of water moving at 12 m/s impinges on vane shaped to deflect the jet through 120° when stationary. If the vane is moving at 5 m/s, find the angle of the jet so that there is no shock at inlet. What is the absolute velocity of the jet at exit in magnitude and direction and the work done per second per unit weight of water striking per second? Assume that the vane is smooth.*

Solution. Given :

Velocity of jet, $V_1 = 12$ m/s

Velocity of vane, $u = u_1 = u_2 = 5$ m/s

Angle of deflection of jet $= 120°$

$\therefore \quad \theta + \phi = 180° - 120° = 60°.$

It is not given that the vane is symmetrical and without this condition problem cannot be solved. Assuming vane to be symmetrical, we have $\theta = \phi$

Then $\theta = \phi = 30°$

(*i*) Angle of jet at inlet with the direction of motion of vane $= \alpha$

In ΔABC, applying sine rule, we have

$$\frac{AB}{\sin(180^\circ - \theta)} = \frac{AC}{\sin(30^\circ - \alpha)} \text{ or } \frac{V_1}{\sin\theta} = \frac{u_1}{\sin(30^\circ - \alpha)} \text{ or } \frac{12}{\sin 30^\circ} = \frac{5}{\sin(30^\circ - \alpha)}$$

$$\therefore \quad \sin(30° - \alpha) = \frac{5 \sin 30^\circ}{12} = 0.2083 = \sin 12.02°$$

$\therefore \quad 30° - \alpha = 12.02°$ or $\alpha = 30° - 12.02° = 17.98°$ or **17° 59′. Ans.**

Again applying sine rule to ΔABC, we have

$$\frac{V_1}{\sin(180^\circ - \theta)} = \frac{V_{r_1}}{\sin\alpha} \text{ or } \frac{12}{\sin\theta} = \frac{V_{r_1}}{\sin 17.98^\circ}$$

$$\therefore \quad V_{r_1} = \frac{12 \sin 17.98^\circ}{\sin\theta} = \frac{12 \times \sin 17.98^\circ}{\sin 30^\circ} = 7.41 \text{ m/s}$$

In ΔABD, $V_{w_1} = V_1 \times \cos\alpha = 12 \cos 17.98° = 11.41$ m/s

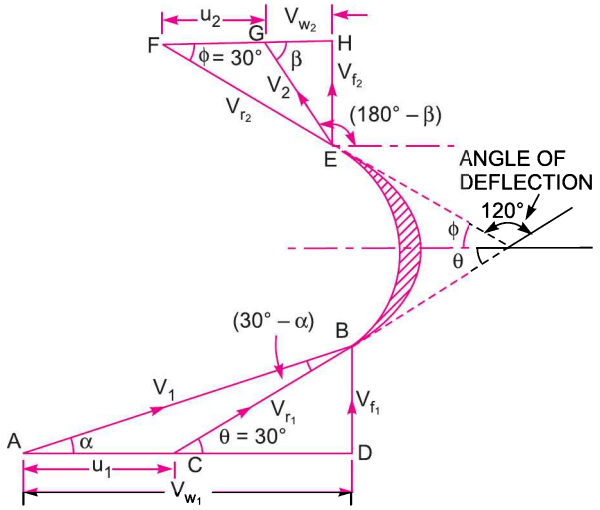

Fig. 17.20

(*ii*) The absolute velocity of jet at outlet = V_2

The angle made by V_2 at outlet with the direction of the motion of vane = $180° - \beta$

Now as vane is given smooth, $V_{r_2} = V_{r_1} = 7.41$ m/s

At outlet, from ΔEFH, we have $V_{r_2} \cos \phi = u_2 + V_{w_2}$ or $7.41 \cos 30° = 5 + V_{w_2}$

$\therefore \quad V_{w_2} = 7.41 \cos 30° - 5.0 = 1.417$ m/s

Also $V_{f_2} = V_{r_2} \sin 30° = 7.41 \sin 30° = 3.705$ m/s

And $$\tan \beta = \frac{V_{f_2}}{V_{w_2}} = \frac{3.705}{1.417} = 2.614 = \tan 69.07°$$

$\therefore \quad \beta = 69.07°$ or $69° 4.2'$

$\therefore$ Angle made by V_2 at outlet with the direction of motion of vane

$= 180° - \beta = 180° - (69° 4.2') =$ **110° 55.8′. Ans.**

Also $$V_2 = \sqrt{V_{f_2}^2 + V_{w_2}^2} = \sqrt{(3.705)^2 + (1.417)^2} = \sqrt{13.727 + 2.007}$$

=3.96 m/s. Ans.

(*iii*) Work done per second per unit weight of water striking per second

$$= \frac{1}{g} [V_{w_1} + V_{w_2}] u = \frac{1}{9.81} [11.41 + 1.417] \times 5 = \textbf{6.537 Nm/N. Ans.}$$

Problem 17.23 *A jet of water having a velocity of 15 m/s, strikes a curved vane which is moving with a velocity of 5 m/s in the same direction as that of the jet at inlet. The vane is so shaped that the jet is deflected through 135°. The diameter of jet is 100 mm. Assuming the vane to be smooth , find :*

(i) Force exerted by the jet on the vane in the direction of motion,

(ii) Power exerted on the vane, and

(iii) Efficiency of the vane.

Solution. Given :

Velocity of jet, $V_1 = 15$ m/s

Velocity of vane, $u = u_1 = u_2 = 5$ m/s

At inlet jet and vane are in the same direction, hence $\alpha = 0$

Diameter of jet, $d = 100$ mm $= 0.1$ m

$\therefore$ Area, $$a = \frac{\pi}{4} (.1)^2 = .007854 \text{ m}^2$$

Angle of deflection of the jet $= 135° = 180° - \phi$ ($\because \theta = 0°$)

$\therefore \quad \phi = 180° - 135° = 45°$

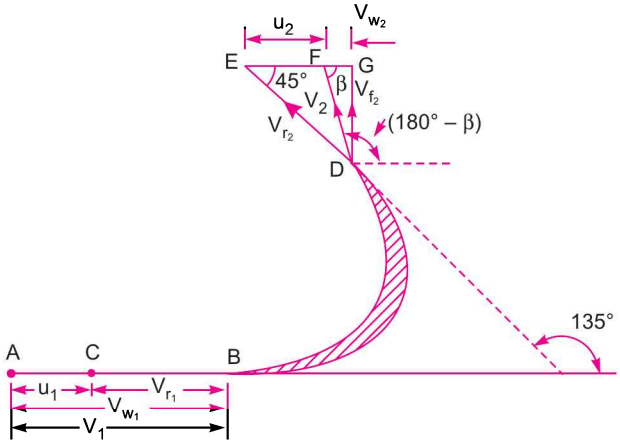

Fig. 17.21

As vane is given smooth hence $V_{r_1} = V_{r_2}$

From the inlet velocity triangle, which is a straight line in this case, we have

$$V_{r_1} = V_1 - u_1 = 15 - 5 = 10 \text{ m/s}$$

$$V_{w_1} = V_1 = 15 \text{ m/s}$$

From the outlet velocity triangle DEG, we have

$$V_{r_2} = V_{r_1} = 10 \text{ m/s}$$

$$u_2 = u_1 = u = 5 \text{ m/s}$$

$$V_{r_2} \cos \phi = u_2 + V_{w_2} \quad \text{or} \quad 10 \cos 45° = 5 + V_{w_2}$$

$$\therefore \quad V_{w_2} = 10 \cos 45° - 5 = 7.07 - 5 = 2.07 \text{ m/s}.$$

(*i*) Force exerted by the jet on the vane in the direction of motion is given by equation (17.19) as

$$F_x = \rho a V_{r_1} [V_{w_1} + V_{w_2}] \text{ (+ve sign is taken as } \beta \text{ is an acute angle)}$$

$$= 1000 \times .007854 \times 10[15 + 2.07] = \mathbf{1340.6 \text{ N. Ans.}}$$

(*ii*) Power of the vane is given as

$$= F_x \times u \text{ N m/s} = 1340.6 \times 5 = 6703 \text{ W} = \mathbf{6.703 \text{ kW. Ans.}}$$

(*iii*) Efficiency of the vane $= \dfrac{\text{Work done per second on vane}}{\text{Kinetic energy supplied by jet per second}}$

$$= \frac{F_x \times u}{\frac{1}{2} \times (\text{mass per second}) \times V^2} = \frac{F_x \times u}{\frac{1}{2} (\rho a V_1) \times V_1^2}$$

$$= \frac{1340.6 \times 5.0}{\frac{1}{2} \times (1000 \times .007854 \times 15) \times 15^2} = \mathbf{0.505 = 50.5\%. \text{ Ans.}}$$

17.4.5 Force Exerted by a Jet of Water on a Series of Vanes. The force exerted by a jet of water on a *single* moving plate (which may be flat or curved) is not practically feasible. This case is only a theoretical one. In actual practice, a large number of plates are mounted on the circumference of a wheel at a fixed distance apart as shown in Fig. 17.22. The jet strikes a plate and due to the force exerted by the jet on the plate, the wheel starts moving and the 2nd plate mounted on the wheel appears before the jet, which again exerts the force on the 2nd plate. Thus each plate appears successively before the jet and the jet exerts force on each plate. The wheel starts moving at a constant speed.

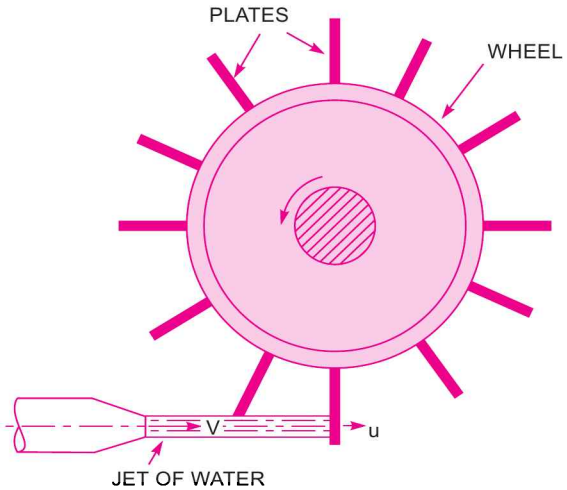

Fig. 17.22 *Jet striking a series of vanes.*

Let V = Velocity of jet,

d = Diameter of jet,

a = Cross-sectional area of jet,

$= \frac{\pi}{4} d^2$

u = Velocity of vane.

In this case the mass of water coming out from the nozzle per second is always in contact with the plates, when all the plates are considered. Hence mass of water per second striking the series of plates = ρaV.

Also the jet strikes the plate with a velocity = $(V - u)$.

After striking, the jet moves tangential to the plate and hence the velocity component in the direction of motion of plate is equal to zero.

$\therefore$ The force exerted by the jet in the direction of motion of plate,

F_x = Mass per second [Initial velocity – Final velocity]

$= \rho aV[(V - u) - 0] = \rho aV[V - u]$ ...(17.22)

Work done by the jet on the series of plates per second

= Force × Distance per second in the direction of force

$= F_x \times u = \rho aV[V - u] \times u$

Kinetic energy of the jet per second

$$= \frac{1}{2} mV^2 = \frac{1}{2} (\rho aV) \times V^2 = \frac{1}{2} \rho aV^3$$

$\therefore$ Efficiency, $$\eta = \frac{\text{Work done per second}}{\text{Kinetic energy per second}} = \frac{\rho aV[V - u] \times u}{\frac{1}{2}\rho aV^3} = \frac{2u[V - u]}{V^2} \quad ...(17.23)$$

Condition for Maximum Efficiency. Equation (17.23) gives the value of the efficiency of the wheel. For a given jet velocity V, the efficiency will be maximum when

$$\frac{d\eta}{du} = 0 \quad \text{or} \quad \frac{d}{du}\left[\frac{2u(V - u)}{V^2}\right] = 0 \quad \text{or} \quad \frac{d}{du}\left[\frac{2uV - 2u^2}{V^2}\right] = 0$$

or $$\frac{2V - 2 \times 2u}{V^2} = 0 \quad \text{or} \quad 2V - 4u = 0 \quad \text{or} \quad V = \frac{4u}{2} = 2u \text{ or } u = \frac{V}{2}. \quad ...(17.24)$$

Maximum Efficiency. Substituting the value of $V = 2u$ in equation (17.23), we get the maximum efficiency as

$$\eta_{max} = \frac{2u\,[2u - u]}{(2u)^2} = \frac{2u \times u}{2u \times 2u} = \frac{1}{2} = 0.5 \text{ or } 50\%. \quad ...(17.25)$$

17.4.6 Force Exerted on a Series of Radial Curved Vanes. For a radial curved vane, the radius of the vane at inlet and outlet is different and hence the tangential velocities of the radial vane at inlet and outlet will not be equal. Consider a series of radial curved vanes mounted on a wheel as shown in Fig. 17.23. The jet of water strikes the vanes and the wheel starts rotating at a constant angular speed.

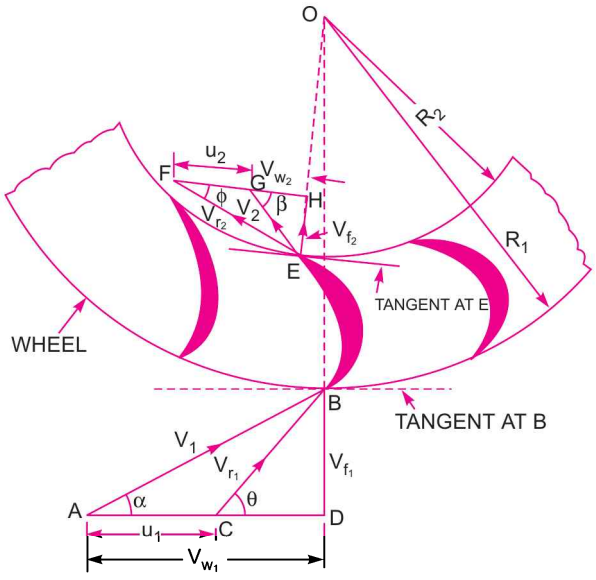

Fig. 17.23 *Series of radial curved vanes mounted on a wheel.*

Let R_1 = Radius of wheel at inlet of the vane,

R_2 = Radius of the wheel at the outlet of the vane,

ω = Angular speed of the wheel.

Then $u_1 = \omega R_1$ and $u_2 = \omega R_2$

The velocity triangles at inlet and outlet are drawn as shown in Fig. 17.23.

The mass of water striking per second for a series of vanes

= Mass of water coming out from nozzle per second

= $\rho a V_1$, where a = Area of jet and V_1 = Velocity of jet.

Momentum of water striking the vanes in the tangential direction per sec at inlet

= Mass of water per second × Component of V_1 in the tangential direction

= $\rho a V_1 \times V_{w_1}$ ($\because$ Component of V_1 in tangential direction = $V_1 \cos \alpha = V_{w_1}$)

Similarly, momentum of water at outlet per sec

= $\rho a V_1$ × Component of V_2 in the tangential direction

= $\rho a V_1 \times (-V_2 \cos \beta) = -\rho a V_1 \times V_{w_2}$ ($\because$ $V_2 \cos \beta = V_{w_2}$)

–ve sign is taken as the velocity V_2 at outlet is in opposite direction.

Now, angular momentum per second at inlet

= Momentum at inlet × Radius at inlet

= $\rho a V_1 \times V_{w_1} \times R_1$

Angular momentum per second at outlet

= Momentum of outlet × Radius at outlet

= $-\rho a V_1 \times V_{w_2} \times R_2$

Torque exerted by the water on the wheel,

T = Rate of change of angular momentum

= [Initial angular momentum per second – Final angular momentum per second]

$= \rho a V_1 \times V_{w_1} \times R_1 - (-\rho a V_1 \times V_{w_2} \times R_2) = \rho a V_1 [V_{w_1} \times R_1 + V_{w_2} R_2]$

Work done per second on the wheel

= Torque × Angular velocity = $T \times \omega$

$= \rho a V_1 [V_{w_1} \times R_1 + V_{w_2} R_2] \times \omega = \rho a V_1 [V_{w_1} \times R_1 \times \omega + V_{w_2} R_2 \times \omega]$

$= \rho a V_1 [V_{w_1} u_1 + V_{w_2} \times u_2]$ $(\because \quad u_1 = \omega R_1$ and $u_2 = \omega R_2)$

If the angle β in Fig. 17.23 is an obtuse angle then work done per second will be given as

$= \rho a V_1 [V_{w_1} u_1 - V_{w_2} u_2]$

$\therefore$ The general expression for the work done per second on the wheel

$= \rho a V_1 [V_{w_1} u_1 \pm V_{w_2} u_2]$ ...(17.26)

If the discharge is radial at outlet, then $\beta = 90°$ and work done becomes as

$= \rho a V_1 [V_{w_1} u_1]$ $(\because \quad V_{w_2} = 0)$ ...(17.27)

Efficiency of the Radial Curved Vane

The work done per second on the wheel is the output of the system whereas the initial kinetic energy per second of the jet is the input. Hence, efficiency of the system is expressed as

$$\text{Efficiency, } \eta = \frac{\text{Work done per second}}{\text{Kinetic energy per second}} = \frac{\rho a V_1 \left[V_{w_1} u_1 \pm V_{w_2} u_2\right]}{\frac{1}{2}(\text{mass/sec}) \times V_1^2}$$

$$= \frac{\rho a V_1 \left[V_{w_1} u_1 \pm V_{w_2} u_2\right]}{\frac{1}{2}(\rho a V_1) \times V_1^2} = \frac{2\left[V_{w_1} u_1 \pm V_{w_2} u_2\right]}{V_1^2}. \qquad \text{...(17.28)}$$

If there is no loss of energy when water is flowing over the vanes, the work done on the wheel per second is also equal to the change in kinetic energy of the jet per second. Hence, the work done per second on the wheel is also given as

Work done per second on the wheel

= Change of K.E. per second of the jet

= (Initial K.E. per second – Final K.E. per second) of the jet

$$= \left(\frac{1}{2} m V_1^2 - \frac{1}{2} m V_2^2\right)$$

$$= \frac{1}{2} m \left(V_1^2 - V_2^2\right) = \frac{1}{2}\left(\rho a V_1^2\right)\left(V_1^2 - V_2^2\right) \qquad (\because \text{mass/second} = \rho a V_1)$$

$$\text{Hence efficiency, } \eta = \frac{\text{Work done per second on the wheel}}{\text{Initial K.E. per second of the jet}}$$

$$= \frac{\frac{1}{2} \rho a V_1^2 \left(V_1^2 - V_2^2\right)}{\frac{1}{2}\left(\rho a V_1^2\right) \cdot V_1^2}$$

$$= \frac{V_1^2 - V_2^2}{V_1^2} = \left(1 - \frac{V_2^2}{V_1^2}\right) \qquad ...(17.28A)$$

From the above equation, it is clear that for a given initial velocity of the jet (*i.e.*, V_1), the efficiency will be maximum, when V_2 is minimum. But V_2 cannot be zero as in that case the incoming jet will not move out of the vane. Equation (17.28) also gives the efficiency of the system. From this equation, it is clear that efficiency will be maximum when V_{w_2} is added to V_{w_1}. This is only posible if β is an acute* angle. Also for maximum efficiency V_{w_2} should also be maximum. This is only possible if $\beta = 0$. In that case $V_{w_2} = V_2$ and angle ϕ will be zero. But in actual practice ϕ cannot be zero. Hence for maximum efficiency, the angle ϕ should be minimum.

Problem 17.24 *If in Problem 17.23, the jet of water instead of striking a single plate, strikes a series of curved vanes, find for the data given Problem 17.23,*

(i) Force exerted by the jet on the vane in the direction of motion,
(ii) Power exerted on the vane, and
(iii) Efficiency of the vane.

Solution. Given :

From Problem 17.23, $V_1 = 15$ m/s, $u = u_1 = u_2 = 5$m/s,
$\alpha = 0$, $a = .007854$ m^2
$\phi = 45°$, $V_{w_1} = 15$ m/s and $V_{w_2} = 2.07$ m/s.

For the series of vanes, mass of water striking per second
= Mass of water coming out from nozzle
$= \rho a V_1 = 1000 \times .007854 \times 15 = 117.72$

(*i*) Force exerted by the jet on the vane in the direction of motion

$$F_x = \rho a V_1 [V_{w_1} + V_{w_2}] = 117.72 [15 + 2.07] = \textbf{2009.5 N. Ans.}$$

(*ii*) Power of the vane in kW

$$= \frac{\text{Work done per second}}{1000} = \frac{F_x \times u}{1000}\text{kW} = \frac{2009.5 \times 5}{1000}$$
$$= \textbf{10.05 kW. Ans.}$$

(*iii*) Efficiency,
$$\eta = \frac{\text{Work done per second}}{\frac{1}{2}(\text{mass of water per sec}) \times V_1^2}$$
$$= \frac{2009.5 \times 5.0}{\frac{1}{2} \times 117.72 \times 15^2} = 0.7586 \text{ or } \textbf{75.86\%}. \quad \textbf{Ans.}$$

Problem 17.25 *A jet of water having a velocity of 35 m/s impinges on a series of vanes moving with a velocity of 20 m/s. The jet makes an angle of 30° to the direction of motion of vanes when entering and leaves at an angle of 120°. Draw the triangles of velocities at inlet and outlet and find :*

(a) the angles of vanes tips so that water enters and leaves without shock,
(b) the work done per unit weight of water entering the vanes, and
(c) the efficiency.

Solution. Given :

Velocity of jet, $V_1 = 35$ m/s
Velocity of vane, $u_1 = u_2 = 20$ m/s
Angle of jet at inlet, $\alpha = 30°$

---

* The work done is equal to torque multiplied by ω(angular velocity). Torque is the rate of change of angular momentum. Due to change of angular momentum (*i.e.*, initial angular momentum – final angular momentum), V_{w_2} should be in opposite direction so that it can be added to V_{w_1}. This is possible if $\beta \angle 90°$.

Angle made by the jet at outlet with the direction of motion of vanes = 120°

$\therefore$ Angle $\beta = 180° - 120° = 60°$

(*a*) *Angle of vanes tips.*

From inlet velocity triangle

$$V_{w_1} = V_1 \cos \alpha = 35 \cos 30° = 30.31 \text{ m/s}$$

$$V_{f_1} = V_1 \sin \alpha = 35 \sin 30° = 17.50 \text{ m/s}$$

$$\tan \theta = \frac{V_{f_1}}{V_{w_1} - u_1} = \frac{17.50}{30.31 - 20} = 1.697$$

$\therefore$ $\theta = \tan^{-1} 1.697 = \mathbf{60°}$. **Ans.**

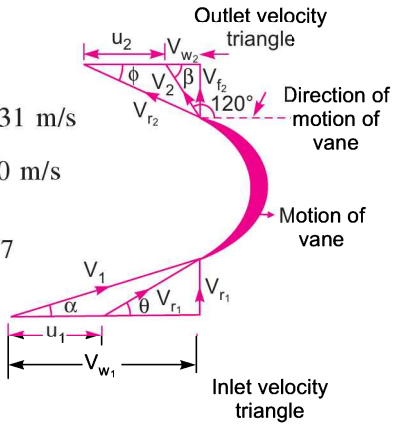

Fig. 17.23(*a*)

By sine rule, $\dfrac{V_{r_1}}{\sin 90°} = \dfrac{V_{f_1}}{\sin \theta}$ or $\dfrac{V_{r_1}}{1} = \dfrac{17.50}{\sin 60°}$

$\therefore$ $V_{r_1} = \dfrac{17.50}{.866} = 20.25$ m/s.

Now, $V_{r_2} = V_{r_1} = 20.25$ m/s

From outlet velocity triangle, by sine rule

$$\frac{V_{r_2}}{\sin 120°} = \frac{u_2}{\sin (60° - \phi)} \quad \text{or} \quad \frac{20.25}{0.886} = \frac{20}{\sin (60° - \phi)}$$

$\therefore$ $\sin (60° - \phi) = \dfrac{20 \times 0.866}{20.25} = 0.855 = \sin (58.75°)$

$60° - \phi = 58.75°$

$\therefore$ $\phi = 60° - 58.75° = \mathbf{1.25°}$. **Ans.**

(*b*) *Work done per unit weight of water entering* $= \dfrac{1}{g}(V_{w_1} + V_{w_2}) \times u_1$ ...(*i*)

$V_{w_1} = 30.31$ m/s and $u_1 = 30$ m/s

The value of V_{w_2} is obtained from outlet velocity triangle

$$V_{w_2} = V_{r_2} \cos \phi - u_2 = 20.25 \cos 1.25° - 20.0 = 0.24 \text{ m/s}$$

$\therefore$ Work done/unit weight $= \dfrac{1}{9.81} [30.31 + 0.24] \times 20 = \mathbf{62.28 \text{ Nm/N}}$. **Ans.**

(*c*) *Efficiency* $= \dfrac{\text{Work done per kg}}{\text{Energy supplied per kg}}$

$$= \frac{62.28}{\frac{V_1^2}{2g}} = \frac{62.28 \times 2 \times 9.81}{35 \times 35} = \mathbf{99.74\%} \text{ Ans.}$$

Problem 17.26 *A jet of water having a velocity of 30 m/s strikes a series of radial curved vanes mounted on a wheel which is rotating at 200 r.p.m. The jet makes an angle of 20° with the tangent to the wheel at inlet and leaves the wheel with a velocity of 5 m/s at an angle of 130° to the tangent to the wheel at outlet. Water is flowing from outward in a radial direction. The outer and inner radii of the wheel are 0.5 m and 0.25 m respectively. Determine :*

(i) Vane angles at inlet and outlet, (ii) Work done per unit weight of water, and

(iii) Efficiency of the wheel.

Solution. Given :

Velocity of jet, $V_1 = 30$ m/s

Speed of wheel, $N = 200$ r.p.m.

$\therefore$ Angular speed, $\omega = \frac{2\pi N}{60} = \frac{2\pi \times 200}{60} = 20.94$ rad/s

Angle of jet at inlet, $\alpha = 20°$

Velocity of jet at outlet, $V_2 = 5$ m/s

Angle made by the jet at outlet with the tangent to wheel = 130°

$\therefore$ Angle, $\beta = 180° - 130° = 50°$

Outer radius, $R_1 = 0.5$ m

Inner radius, $R_2 = 0.25$ m

$\therefore$ Velocity $u_1 = \omega \times R_1 = 20.94 \times 0.5 = 10.47$ m/s

And $u_2 = \omega \times R_2 = 20.94 \times 0.25 = 5.235$ m/s.

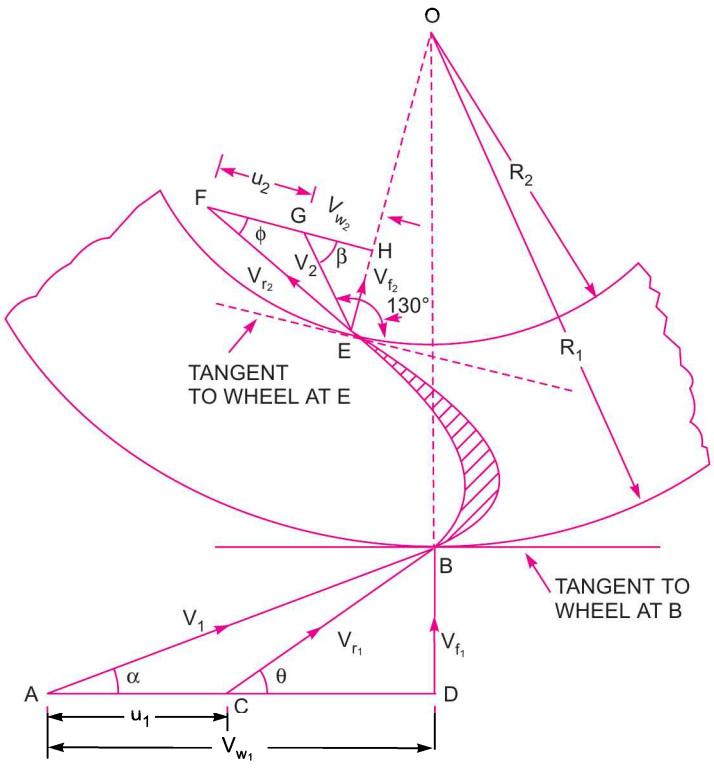

Fig. 17.24

(*i*) **Vane angles** at inlet and outlet means the angle made by the relative velocities V_{r_1} and V_{r_2}, *i.e.*, angle θ and ϕ.

From ΔABD, $V_{w_1} = V_1 \cos \alpha = 30 \times \cos 20° = 28.19$ m/s

$$V_{f_1} = V_1 \sin \alpha = 30 \times \sin 20° = 10.26 \text{ m/s}$$

In ΔCBD, $$\tan \theta = \frac{BD}{CD} = \frac{V_{f_1}}{AD - AC} = \frac{10.26}{V_{w_1} - u_1} = \frac{10.26}{28.19 - 10.47} = 0.579 = \tan 30.07$$

$\therefore$ $\theta = 30.07°$ or **30° 4.2′. Ans.**

From outlet velocity Δ, $V_{w_2} = V_2 \cos \beta = 5 \times \cos 50° = 3.214$ m/s

$$V_{f_2} = V_2 \times \sin \beta = 5 \sin 50° = 3.83 \text{ m/s}$$

In ΔEFH, $$\tan \phi = \frac{V_{f_2}}{u_2 + V_{w_2}} = \frac{3.83}{5.235 + 3.214} = 0.453 = \tan 24.385°$$

$\therefore$ $\phi = 24.385°$ or **24° 23.1′. Ans.**

(*ii*) Work done per second by water is given by equation (17.26)

$$= \rho a V_1 \left[V_{w_1} u_1 + V_{w_2} u_2\right]$$

(+ ve sign is taken as β is acute angle in Fig.17.24)

$\therefore$ Work done* per second per unit weight of water striking per second

$$= \frac{\rho a V_1 \left[V_{w_1} u_1 + V_{w_2} u_2\right]}{\text{Weight of water/s}} = \frac{\rho a V_1 \left[V_{w_1} u_1 + V_{w_2} u_2\right]}{\rho a V_1 \times g}$$

$$= \frac{1}{g}\left[V_{w_1} u_1 + V_{w_2} u_2\right] \text{Nm/N} = \frac{1}{9.81} [28.19 \times 10.47 + 3.214 \times 5.235]$$

$$= \frac{1}{9.81} [295.15 + 16.82] = \mathbf{31.8\ Nm/N.\ Ans.}$$

(*iii*) Efficiency, η is given by equation (17.28) as

$$\eta = \frac{2\left[V_{w_1} u_1 + V_{w_2} u_2\right]}{V_1^2} = \frac{2[28.19 \times 10.47 + 3.214 \times 5.235]}{30^2}$$

$$= \frac{2[295.15 + 16.82]}{30 \times 30} = 0.6932 \text{ or } \mathbf{69.32\%.\ Ans.}$$

▶ 17.5 JET PROPULSION

Jet propulsion means the propulsion or movement of the bodies such as ships, aircrafts, rocket etc., with the help of jet. The reaction of the jet coming out from the orifice provided in the bodies is used to move the bodies. This is explained as given below.

* Work done per second per unit weight striking per second is same as work done per unit weight of water.

A jet of fluid coming out from an orifice or nozzle, when strikes a plate, exerts a force on the plate. The magnitude of the force exerted on the plate can be determined depending upon whether plate is flat, inclined, curved, stationary or moving. This force exerted by the jet on the plate is called as '*action of the jet*'. But according to Newtons third law of motion, every action is accompanied by an equal and opposite reaction. Hence the jet while coming out of the orifice or nozzle, exerts a force on the orifice or nozzle in the opposite direction in which jet is coming out. The magnitude of the force exerted is equal to the 'action of the jet'. This force which is acting on the orifice or nozzle in the opposite direction is called the 'reaction of the jet'. If the body in which orifice or nozzle is fitted, is free to move, the body will start moving in the direction opposite to the jet. The following cases are important where this principle is used :

(*a*) Jet propulsion of a tank to which orifice is fitted, and

(*b*) Jet propulsion of ships.

17.5.1 Jet Propulsion of a Tank with an Orifice. Consider a large tank fitted with an orifice in one of its sides as shown in Fig. 17.25.

Let H = Constant head of water in tank from the centre of orifice,

a = Area of orifice,

V = Velocity of the jet of water,

C_v = Co-efficient of the velocity of orifice.

Then $V = C_v \sqrt{2gH}$

And mass of water coming out from the orifice per second

= ρ × Volume per second = ρ × (Area × Velocity)

= ρ × a × V

Force acting on the water is equal to the rate of change of momentum.

or F = Mass per second × [Change of velocity]

= Mass per second × [Final velocity – Initial velocity].

Note. Here change of velocity is to be taken as final minus initial as we are finding force on water and not force exerted by water.

Initial velocity of water in the tank is zero and final velocity of water when it comes out in the form of jet is equal to V.

$\therefore$ $F = \rho a V\,[V - 0] = \rho a V^2$ ...(17.29)

Thus, F is the force exerted on the jet of water. This jet of water will exert a force on the tank which is equal to F but opposite in direction as shown in Fig. 17.25. The force will be acting at A, the point on the tank in the horizontal line of the centre of the orifice. If the tank is free to move or the tank is fitted with frictionless wheel, it will start moving with some velocity say, 'u' in the direction opposite to the direction of the jet. When the tank starts moving, the velocity of the jet with which it comes out of the orifice will not be equal to V but it will be equal to the relative velocity of the jet with respect to tank.

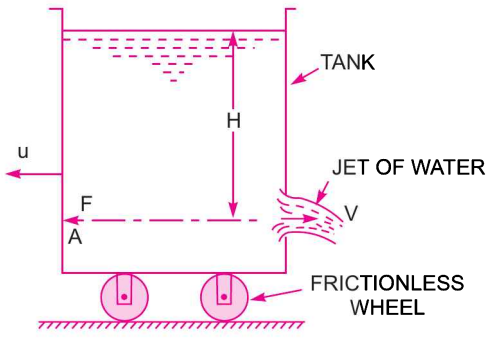

Fig. 17.25 *Jet propulsion of a tank with an orifice.*

Hence if V = Absolute velocity of jet,

u = Velocity of tank,

V_r = Velocity of jet with respect to tank

Then V_r = Vectorial difference of absolute velocity (V) and velocity of tank (u)
$= V - (-u)$(as u is in opposite direction to V hence velocity of tank is taken as $-u$)
$= V + u$

Hence when the tank is moving, the velocity with which jet comes out from the orifice is $(V + u)$.

Mass of water coming out from the orifice per sec
$= \rho \times a \times$ Velocity with which water comes out
$= \rho \times a \times (V_r) = \rho a\,(V + u)$

$\therefore$ Force exerted on the tank is given as
F_x = Mass of water coming out from orifice per second $\times$ [Change of velocity]*
$= \rho a(V + u) \times [(V + u) - u] = \rho a\,[V + u]\,[V]$
$= \rho a[V + u] \times V$ ...(17.30)

Thus, the force given by equation (17.30) is used for propelling the tank.

$\therefore$ Work done on the moving tank by jet per second
$= F_x \times u = \rho a(V + u) \times V \times u$

$\therefore$ Efficiency of propulsion is given as,

$$\eta = \frac{\text{Work done per second}}{\text{Kinetic energy of the issuing jet per second}}$$

$$= \frac{\rho a(V+u)\times V \times u}{\frac{1}{2}(\text{Mass of water issuing per second})\times(\text{Velocity of issuing jet})}$$

$$= \frac{\rho a(V+u)\times V \times u}{\frac{1}{2}\left[\rho a(V+u)\right]\times(V+u)^2} = \frac{2Vu}{(V+u)^2} \quad \text{...(17.31)}$$

Condition for Maximum Efficiency and Expression for Maximum η. For a given value of V, the efficiency will be maximum when $\frac{d\eta}{du} = 0$

or $$\frac{d}{du}\left[\frac{2Vu}{(V+u)^2}\right] = 0 \quad \text{or} \quad \frac{d}{du}\left[2Vu\times(V+u)^{-2}\right] = 0$$

or $$2Vu \times (-2)\,(V+u)^{-3} + (V+u)^{-2} \times 2V = 0$$

or $$\frac{-4Vu}{(V+u)^3} + \frac{2V}{(V+u)^2} = 0 \quad \text{or} \quad -4Vu + 2V(V+u) = 0$$

Dividing by $2V$, $-2u + (V + u) = 0$ or $-u + V = 0$ or $u = V$ ...(17.32)

Equation (17.32) is the condition for maximum efficiency. Substituting equation (17.32) in equation (17.31), the value of maximum efficiency is obtained as

$$\eta_{max} = \frac{2\times u\times u}{(u+u)^2} = \frac{2u^2}{4u^2} = \frac{1}{2} = 0.5 \text{ or } 50\%. \quad \text{...(17.32A)}$$

---

* Change of velocity is the final velocity minus initial velocity of jet of water coming out from the orifice. The final velocity of the jet with respect to tank is $(V + u)$. This velocity is obtained by applying a velocity u to the whole system (*i.e.*, tank, water in the tank and jet of water) in a direction opposite to the motion of tank. Then final velocity of jet becomes as $(V + u)$ and initial velocity of water as u. Hence change of velocity is $(V + u) - u$.

Problem 17.27 *The head of water from the centre of the orifice which is fitted to one side of the tank is maintained at 2 m of water. The tank is not allowed to move and the diameter of orifice is 100 mm. Find the force exerted by the jet of water on the tank. Take C_v = 0.97 cm.*

Solution. Given :

Head of water, $H = 2$ m

Diameter of orifice, $d = 100$ mm $= 0.1$ m

$\therefore$ Area, $a = \frac{\pi}{4}d^2 = \frac{\pi}{4}(.1)^2 = .007854$ m^2

Value of $C_v = 0.97$

$\therefore$ Velocity of jet, $V = C_v \times \sqrt{2gH} = 0.97 \times \sqrt{2 \times 9.81 \times 2.0} = 6.07$ m/s

Force exerted on the tank is given by equation (17.29) as

$$F = \rho a V^2 = 1000 \times .007854 \times 6.072 = \textbf{289.3 N. Ans.}$$

Problem 17.28 *If in the above problem, the tank is fitted with frictionless wheels and allowed to move, determine*

(i) Propelling force on tank, *(ii) Work done by the propelling force per second, and*

(iii) Efficiency of propulsion.

The tank is moving with a velocity of 2 m/s.

Solution. Given :

$H = 2$ m, $d = 100$ mm, $a = .007854$ m^2, $C_v = 0.97$

and velocity of jet, $V = 6.07$ m/s.

Velocity of tank, $u = 2$ m/s.

(*i*) Propelling force is given by equation (17.30) as

$$F_x = \rho a(V + u) \times V$$
$$= 1000 \times .007854 \times (6.07 + 2.0) \times 6.07 = \textbf{384.65 N. Ans.}$$

(*ii*) Work done by the propelling force per second

$$= F_x \times u = 384.65 \times 2.0 = \textbf{769.3 N m/s. Ans.}$$

(*iii*) Efficiency of propulsion is given by equation (17.31) as

$$\eta = \frac{2Vu}{(V+u)^2} = \frac{2 \times 6.07 \times 2.0}{(6.07+2.0)^2} = \textbf{0.3728 or 37.28\%. Ans.}$$

17.5.2 Jet Propulsion of Ships. By the application of the jet propulsion principle, a ship is driven through water. A jet of water which is discharged at the back (also called stern) of the ship, exerts a propulsive force on the ship. The ship carries centrifugal pumps which draw water from the surrounding sea. This water is discharged through the orifice provided at the back of the ship in the form of a jet. The reaction of the jet coming out at the back of the ship propels the ship in the opposite direction of the jet. The water from the surrounding sea by the centrifugal pump is taken by the following two ways :

1. Through inlet orifices which are at right angles to the direction of the motion of the ship, and
2. Through the inlet orifices, which are facing the direction of motion of the ship.

1st Case. Jet propulsion of the ship when the inlet orifices are at right angles to the direction of the motion of the ship.

Fig. 17.26 shows a ship which is having the inlet orifices at right angles to its direction.

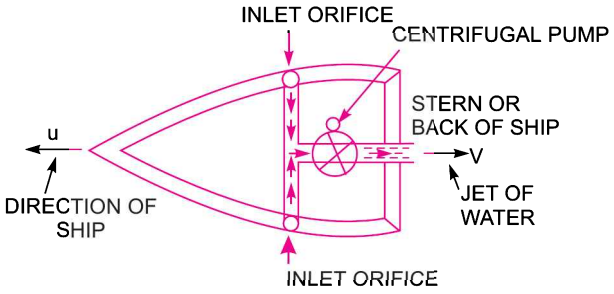

Fig. 17.26 *Inlet orifices are at right angles.*

Let V = Absolute velocity of jet of water coming at the back of the ship,
u = Velocity of the ship,
V_r = Relative velocity of jet with respect to ship
= $(V + u)$.

As the velocity V and u are in opposite direction and hence relative velocity will be equal to the sum of these two velocities.

Mass of water issuing from the orifice at the back of the ship = $\rho a V_r = \rho a(V + u)$,
where a = Area of the jet of water

$\therefore$ Propulsive force exerted on the ship

F = Mass of water issuing per sec × Change of velocity*

$= \rho a(V + u)\,[V_r - u] = \rho a(V + u)\,[(V + u) - u] = \rho a(V + u) \times V$ ...(17.33)

Work done per second $= F \times u = \rho a\,(V + u) \times V \times u$ ...(17.34)

The efficiency of propulsion, the condition of maximum efficiency and expression for maximum efficiency are given by equations (17.31), (17.32) and (17.32 *A*) respectively.

Note. (*i*) When the inlet orifices are at right angles to the direction of motion of the ship, then this case is also known as water is drawn **AMID SHIP** which means the water is drawn at the middle of the ship.

(*ii*) The centrifugal pump draws the water from the surrounding sea and discharges through orifice. The kinetic energy of the issuing jet is $\frac{1}{2}$ × mass × velocity ^{2} *i.e.*, $\frac{1}{2}\,[\rho a(V + u)] \times [V + u]^2 = \frac{1}{2}\,\rho a(V + u)^3$. This energy is provided by centrifugal pump *i.e.*, work is done by pump to provide this energy.

Problem 17.29 *Find the propelling force acting on a ship which takes water through inlet orifices which are at right angles to the direction of motion of ship, and discharges at the back through orifices having effective areas of 0.04 m^2. The water is flowing at the rate of 1000 litres/s and ship is moving with a velocity of 8 m/s.*

Solution. Given :

Effective areas of orifices, $a = 0.04$ m^2

Discharge of water, $Q = 1000$ litres/s $= 1$ m^3/s

$\therefore$ Velocity of jet relative to water $= \dfrac{Q}{a} = \dfrac{1}{.04} = \dfrac{100}{4} = 25$ m/s or $V_r = 25$ m/s

---

* To find the change of velocity, apply a velocity u to the whole system (*i.e.*, ship, jet of water and surrounding water in the sea) in a direction opposite to the motion of ship. Then final velocity of jet of water becomes as $(V + u)$. And velocity of water in sea becomes as u. Hence change of velocity becomes $(V + u) - u$.

Velocity of ship, $u = 8$ m/s

Now, $V_r = u + V$, where V = Absolute velocity of jet

$\therefore$ $25 = 8 + V$ or $V = 25 - 8 = 17$ m/s

Propelling force is given by equation (17.33) as,

$$F = \rho a\,(V + u) \times V$$
$$= 1000 \times .04 \times (17 + 8) \times 17 = \textbf{16999.94 N. Ans.}$$

Problem 17.30 *The water in a jet propelled boat is drawn amid-ship and discharged at the back with an absolute velocity of 20 m/s. The cross-sectional area of the jet at the back is 0.02 m^2 and the boat is moving in sea water with a speed of 30 km/hour. Determine :*

(i) Propelling force on the boat, (ii) Power required to drive the pump, and

(iii) Efficiency of the jet propulsion.

Solution. Given :

'Water is drawn amid-ship' means water is drawn at the middle of the ship and inlet orifices are at right angles to the motion of ship.

Absolute velocity of jet, $V = 20$ m/s

Area of the jet, $a = 0.02$ m^2

Speed of boat, $u = 30$ km/hr $= \dfrac{30 \times 1000}{60 \times 60} = 8.33$ m/s.

(*i*) Propelling force is given by equation (17.33) as

$$F = \rho a(V + u) \times V$$
$$= 1000 \times .02(20 + 8.33) \times 20 = \textbf{11332 N. Ans.}$$

(*ii*) Power required to drive the pump in kW

$$= \frac{\text{Work done per sec}}{1000} = \frac{F \times u}{1000} = \frac{11332 \times 8.33}{1000} = \textbf{94.395 kW. Ans.}$$

(*iii*) Efficiency of the jet propulsion is given by (17.31) as

$$\eta = \frac{2Vu}{(V+u)^2} = \frac{2 \times 20 \times 8.33}{(20+8.33)^2} = \textbf{0.415 or 41.5\%. Ans.}$$

Problem 17.31 *A small ship is fitted with jets of total area 0.65 m^2. The velocity through the jet is 9 m/s and speed of the ship is 18 km p.h. in sea-water. The efficiencies of the engine and pump are 85% and 65% respectively. If the water is taken amid-ships, determine the propelling force and the overall efficiency, assuming the pipe losses to be 10% of the kinetic energy of the jets.*

Solution. Given :

Total area of jets, $a = 0.65$ m^2

Velocity through the jet relative to ship, $V_r = 9$ m/s

Speed of ship, $u = 18$ km/hour $= \dfrac{18 \times 1000}{60 \times 60}$ m/s $= 5$ m/s

Efficiency of the engine, $\eta_E = 85\% = 0.85$

Efficiency of the pump, $\eta_P = 65\% = 0.65$

Pipe losses, h_f = 10% of kinetic energy of the jet

$$= \frac{10}{100} \times \frac{V_r^2}{2g} = \frac{V_r^2}{20g}$$

Now, $V_r = u + V$, where V = Absolute velocity of jet

$\therefore$ $9 = 5 + V$ or $V = 9 - 5 = 4$ m/s.

(*i*) Propelling force is given by equation (17.33) as

$$F = \rho a\,(V + u) \times V$$

$$= 1000 \times 0.65 \times (4 + 5) \times 4 = \textbf{23400 N. Ans.}$$

(*ii*) Work done by the jets per second

$$= F \times u = 23400 \times 5 = 117000 \text{ Nm/s}$$

Weight of water issuing from the jets per second

$$= g \times \text{Mass of water per second}$$

$$= g \times \rho a V_r = 9.81 \times 1000 \times 0.65 \times 9 = 57388.5 \text{ N/s.}$$

The pump should have the output which will give the jet a relative velocity (V_r) and also overcome the pipe losses.

$\therefore$ Output of the pump per unit weight of water

$$= \text{Kinetic energy of jet + Pipe losses}$$

$$= \frac{V_r^2}{2g} + \frac{V_r^2}{20g} = \frac{V_r^2}{2g}\,(1 + 0.1) = \frac{V_r^2}{2g} \times 1.1$$

Input to the pump per unit weight of water

$$= \frac{\text{Output of pump}}{\text{Efficiency of pump}} = \frac{1.1\,V_r^2}{2g \times 0.65}$$

The input to the pump is equal to the output of the engine. Hence input to the engine per unit weight of water

$$= \frac{1.1\,V_r^2}{2g \times 0.65 \times \text{Efficiency of engine}}$$

$$= \frac{1.1\,V_r^2}{2g \times 0.65 \times 0.85} = \frac{1.1 \times 9^2}{2 \times 9.81 \times 0.65 \times 0.85} = 8.22 \text{ Nm/N}$$

$\therefore$ Total input to the engine = Weight of water $\times$ Input per unit weight of water

$$= 57388.5 \times 8.22 = 471733.5 \text{ Nm}$$

$\therefore$ Overall efficiency, $\eta_o = \dfrac{\text{Work done by jets}}{\text{Total input to engine}} = \dfrac{117000}{471733.5} = 0.248 = \textbf{24.80\%. Ans.}$

Problem 17.32 *A jet propelled boat, moving with a velocity of 5 m/s, draws water amid-ship. The water is discharged through two jets provided at the back of the ship. The diameter of each jet is 150 mm. The total resistance offered to the motion of the boat is 4905 N (500 × 9.81 N). Determine :*

(i) Volume of water drawn by the pump per second, and

(ii) Efficiency of the jet propulsion.

Solution. Given :

Velocity of boat, $u = 5$ m/s

Diameter of each jet, $d = 150$ mm $= 0.15$ m

Area of each jet $= \frac{\pi}{4}(.15)^2 = 0.01767$ m^2

$\therefore$ Total area of the jets, $a = 2 \times .01767 = .03534$ m^2

Total resistance to motion $= 4905$ N $(500 \times 9.81$ N$)$

The propelling force must be equal to the resistance to the motion.

$\therefore$ Propelling force, $F = 4905$ N or $(500 \times 9.81$ N$)$

Propelling force is given by equation (17.33) as

$$F = \rho a\,(V + u)\,V$$

$$500 \times 9.81 = 1000 \times 0.03534 \times (V + 5) \times V$$

or $$500 = \frac{1000}{9.81} \times .03534 \times (V + 5) \times V$$

$$= 3.6\,(V + 5)\,V = 3.6V^2 + 3.6 \times 5V = 3.6\,V^2 + 18V$$

or $$3.6\,V^2 + 18V - 500 = 0$$

The above equation is quadratic and its solution is

$$V = \frac{-18 \pm \sqrt{18^2 + 4 \times 3.6 \times 500}}{2 \times 3.6} = \frac{-18 \pm 86.74}{7.2}$$

$$= \frac{86.74 - 18}{2} = 34.37 \text{ m/s} \qquad \text{[–ve value is not possible]}$$

(*i*) Volume of water drawn by the pump per second is equal to the volume of water discharged through the orifices at the back in the form of jets and this volume

$$= aV_r = a(V + u)$$

$$= .03534 \times (34.37 + 5.0) = \mathbf{1.39\ m^3/s.}\ \textbf{Ans.}$$

(*ii*) Efficiency of the jet propulsion is given by equation (17.31) as

$$\eta = \frac{2Vu}{(V + u)^2} = \frac{2 \times 34.37 \times 5.0}{(34.37 + 5.0)^2} = .2217 \text{ or } \mathbf{22.17\%.}\ \textbf{Ans.}$$

2nd Case. Jet propulsion of ship when the inlet orifices face the direction of motion of the ship. Fig. 17.27 shows a ship which is having the inlet orifices facing the direction of the motion of the ship. In this case the expression for propelling force and work done per second will be same as in the 1st case in which inlet orifices are at right angles to the ship. But the energy supplied by the jet will be different,

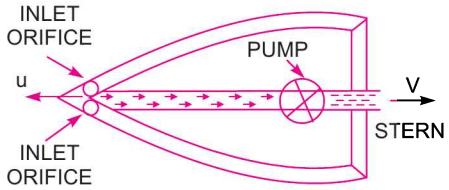

Fig. 17.27 *Inlet orifices facing the direction of ship.*

as in this case the water enters with a velocity equal to the velocity of the ship, *i.e.,* with a velocity u. Hence the expression for the energy supplied by the jet.

$$= \frac{1}{2} \text{ (Mass of water supplied per sec)} \times [V_r^2 - u^2]$$

$$= \frac{1}{2} (\rho a V_r) \times [V_r^2 - u^2]$$

where $V_r = (V + u)$ as in the previous case

$$\therefore \quad \text{K.E. supplied by jet} \quad = \frac{1}{2}\rho a(V + u)\,[(V + u)^2 - u^2] \qquad ...(17.35)$$

$$\therefore \quad \text{Efficiency of propulsion, } \eta = \frac{\text{Work done per sec by jet}}{\text{Energy supplied by jet}}$$

$$= \frac{\rho a(V + u) \times V \times u}{\frac{1}{2}\rho a(V + u)\left[(V + u)^2 - u^2\right]}$$

$$\{\because \text{ From equation (17.34) work done} = \rho a\,(V + u)\,V \times u\}$$

$$= \frac{2V \times u}{(V + u)^2 - u^2} = \frac{2Vu}{V^2 + u^2 + 2Vu - u^2} = \frac{2Vu}{V^2 + 2Vu} = \frac{2u}{V + 2u} \qquad ...(17.36)$$

Problem 17.33 *The water in a jet propelled boat is drawn through inlet openings facing the direction of motion of the ship. The boat is moving in sea-water with a speed of 30 km/hour. The absolute velocity of the jet of the water discharged at the back is 20 m/s and the area of the jet of water is 0.03 m^2. Find the propelling force and efficiency of propulsion.*

Solution. Given :

Speed of boat, $u = 30 \text{ km/hr} = \dfrac{30 \times 1000}{60 \times 60} = 8.33 \text{ m/s}$

Absolute velocity of jet, $V = 20$ m/s

Area of the jet, $a = .03 \text{ m}^2$.

(*i*) Propelling force is given by equation (17.33) as

$$F = \rho a\,(V + u) \times V = 1000 \times .03 \times (20 + 8.33) \times 20 = 16997.98 \text{ N.}$$

(*ii*) Efficiency of propulsion is given by equation (17.36) as

$$\eta = \frac{2u}{V + 2u} = \frac{2 \times 8.33}{20 + 2 \times 8.33} = \mathbf{0.4544} \text{ or } \mathbf{45.44\%}. \textbf{ Ans.}$$

HIGHLIGHTS

1. The force exerted by a jet of water on a stationary plate in the direction of the jet is given by

$F_x = \rho a V^2$ ...for a vertical plate

$= \rho a V^2 \sin^2 \theta$ ...for an inclined plate

$= \rho a V^2 (1 + \cos \theta)$ ...for a curved plate and jet strikes at the centre

$= 2\rho a V^2 \cos \theta$ ...for a curved plate and jet strikes at one of the tips of the jet.

where V = Velocity of the jet,

θ = Angle between the jet and the plate for inclined plate,

= Angle made by the jet with the direction of motion for curved plates.

2. When a jet of water strikes a vertical hinged plate, the angle of swing about the hinge is given by

$$\sin \theta = \frac{\rho a V^2}{W}$$

where V = Velocity of the jet of water, W = Weight of the hinged plate.

3. The force exerted by a jet of water on a moving plate, in the direction of the motion of the plate, is given by

$F_x = \rho a (V - u)^2$ ...for a moving vertical plate,

$= \rho a (V - u)^2 \sin^2 \theta$ ...for an inclined moving plate,

$= \rho a (V - u)^2 (1 + \cos \theta)$ ...when jet strikes the curved plate at the centre

4. When a jet of water strikes a curved moving plate at one of its tips and comes out at the other tip, the force exerted and work done are obtained from velocity triangles at inlet and outlet. The expression for force and work done are

$$F_x = \rho a V_{r_1} \left[V_{w_1} \pm V_{w_2} \right]$$

$$\text{Work done per second} = \rho a V_{r_1} \left[V_{w_1} \pm V_{w_2} \right] \times u$$

+ve sign is taken when β is an acute angle. If β is an obtuse angle then –ve sign is taken. If β is 90°, $V_{w_2} = 0$.

$$\text{Work done per second per kg of fluid} = \frac{1}{g}\left[V_{w_1} \pm V_{w_2} \right].$$

5. For a series of vanes, the force and work done are given as $F_x = \rho a V_{r_1} \left[V_{w_1} \pm V_{w_2} \right]$

$$\text{Work done/sec} = \rho a V_{r_1} \left[V_{w_1} \pm V_{w_2} \right] \times u$$

$$\text{Work done/sec per kg} = \frac{1}{g}\left[V_{w_1} \pm V_{w_2} \right] \times u.$$

6. Efficiency of a series of vanes is given as $\eta = \dfrac{2u(V-u)}{V^2}$

and condition of max. η is $u = \dfrac{V}{2}$

Max. $\eta = 50\%$.

7. For a curved radial vane, the work done per second $= \rho a V_1 \left[V_{w_1} u_1 \pm V_{w_2} u_2 \right]$

where V_1 = Absolute velocity of jet at inlet, V_{w_1} = Velocity of whirl at inlet

u_1 = Tangential velocity of vane at inlet, V_{w_2} = Velocity of whirl at outlet

u_2 = Tangential velocity of vane at outlet.

8. For a curved radial vane the efficiency is given by

$$\eta = \frac{\rho a V_1 \left[V_{w_1} u_1 \pm V_{w_2} u_2\right]}{\frac{1}{2}(\rho a V_1) \times V_1^2} = \frac{2\left[V_{w_1} u_1 \pm V_{w_2} u_2\right]}{V_1^2}.$$

9. Jet propulsion means the propulsion of a vessel with the help of the jet. The reaction of the jet is used for propelling the vessel. The propelling force exerted on a tank with a orifice is given by

$$F_x = \rho a\,(V + u) \times V$$

where V = Absolute velocity of the jet of water, u = Velocity of the tank.

10. The efficiency of propulsion is given by $\eta = \dfrac{2Vu}{(V+u)^2}$ and u = V for maximum efficiency

$\therefore$ Maximum $\eta = 50\%$.

11. Ships are also propelled by jets. The intake water by the centrifugal pump is taken by two ways. In one case, the water is taken from orifices which are at right angles to the direction of the motion of the ship and in the other case the water is taken through orifices which are facing the direction of motion of the ship.

EXERCISE

(A) THEORETICAL PROBLEMS

1. Define the terms : (*a*) Impact of jets, and (*b*) Jet propulsion.

2. Obtain an expression for the force exerted by a jet of water on a fixed vertical plate in the direction of the jet.

3. Show that the force exerted by a jet of water on an inclined fixed plate in the direction of the jet is given by,

$$F_x = \rho a V^2 \sin^2 \theta$$

where a = Area of the jet, V = Velocity of the jet

and θ = Inclination of the plate with the jet.

4. Prove that the force exerted by a jet of water on a fixed semi-circular plate in the direction of the jet when the jet strikes at the centre of the semi-circular plate is two times the force exerted by the jet on an fixed vertical plate.

5. Show that the angle of swing of a vertical hinged plate is given by $\sin\theta = \dfrac{\rho a V^2}{W}$

where V = Velocity of the jet striking the plate, a = Area of the jet, and W = Weight of the plate.

6. Differentiate between : (*i*) the force exerted by a jet of water on a fixed vertical plate and moving vertical plate, and (*ii*) the force exerted by a jet on a single curved moving plate and a series of curved moving plate.

7. Prove that the work done per second on a series of moving curved vanes by a jet of water striking at one of the tips of the vane is given by,

$$\text{Work done/sec} = \rho a V_1 \left[V_{w_1} \pm V_{w_2}\right] \times u.$$

8. Find an expression for the efficiency of a series of moving curved vanes when a jet of water strikes the vanes at one of its tips. Prove that maximum efficiency is when $u = V$ and the value of maximum efficiency is 50%.

9. Show that for a curved radial vane, the work done per second is given by, $\rho a V_1 \left[V_{w_1} u_1 \pm V_{w_2} u_2 \right]$.
10. Find an expression for the propelling force and the work done per second on a tank which is provided with an orifice through which jet of water is coming out and tank is free to move.
11. Show that the efficiency of a free jet striking normally on a series of flat plates mounted on the periphery of a wheel can never exceed 50%.
12. Show that the force exerted by a jet of water on moving inclined plate in the direction of jet is given by

$$F_x = \rho a (V - u)^2 \sin^2\theta$$

where a = area of jet,
θ = inclination of the plate with the jet, and
V = velocity of jet. *(J.N.T.U., Hyderabad, S 2002)*

(B) NUMERICAL PROBLEMS

1. Find the force exerted by a jet of water of diameter 100 mm on a stationary flat plate, when the jet strikes the plate normally with a velocity of 30 m/s. [**Ans.** 7068.6 N]
2. A jet of water of diameter 50 mm moving with a velocity of 20 m/s strikes a fixed plate in such a way that the angle between the jet and the plate is 60°. Find the force exerted by the jet on the pate (*i*) in the direction normal to the plate, and (*ii*) in the direction of the jet. [**Ans.** (*i*) 680.13 N, (*ii*) 589 N]
3. A jet of water of diameter 100 mm moving with a velocity of 30 m/s strikes a curved fixed symmetrical plate at the centre. Find the force exerted by the jet of water in the direction of the jet, if the jet is deflected through an angle of 120° at the outlet of the curved plate. [**Ans.** 10602.7 N]
4. A jet of water of the diameter 100 mm moving with a velocity of 20 m/s strikes a curved fixed plate tangentially at one end at an angle of 30° to the horizontal. The jet leaves the plate at an angle of 20° to the horizontal. Find the force exerted by the jet on the plate in the horizontal and vertical directions. [**Ans.** 5672.34 N, 496.3 N]
5. A jet of water of 30 mm diameter, moving with a velocity of 15 m/s, strikes a hinged square plate of weight 245.25 N at the centre of the plate. The plate is of uniform thickness. Find the angle through which the plate will swing. [**Ans.** $\theta = 40° 25.6'$]
6. A plate is acted upon at its centre by a jet of water of diameter 20 mm with a velocity of 20 m/s. The plate is hinged and is deflected through an angle of 15°. Find the weight of the plate. If the plate is not allowed to swing, what will be the force required at the lower edge of the plate to keep the plate in vertical position. [**Ans.** 485.5 N, 62.8 N]
7. A jet of water of diameter 150 mm strikes a flat plate normally with a velocity of 12 m/s. The plate is moving with a velocity of 6 m/s in the direction of the jet and away from the jet. Find : (*i*) the force exerted by the jet on the plate, (*ii*) work done by the jet on the plate per second, (*iii*) power of the jet, and (*iv*) efficiency of the jet. [**Ans.** (*i*) 636.3 N, (*ii*) 3817.6 Nm/s, (*iii*) 3.82 kW, (*iv*) 25%]
8. If in the problem 7, the jet strikes the plate in such a way that the normal on the plate makes an angle of 30° to the axis of the jet, find : (*i*) The normal force exerted on the plate, (*ii*) power, and (*iii*) efficiency of the jet. [**Ans.** (*i*) 551 N, (*ii*) 2.86 kW, (*iii*) 18.74%]
9. A jet of water of diameter 100 mm strikes a curved plate at its centre with a velocity of 15 m/s. The curved plate is moving with a velocity of 7 m/s in the direction of the jet. The jet is deflected through an angle of 150°. Assuming the plate smooth find : (*i*) force exerted on the plate in the direction of the jet, (*ii*) power of the jet, and (*iii*) efficiency. [**Ans.** (*i*) 938 N (*ii*) 6.56 kW, (*iii*) 49.53%]
10. A jet of water having a velocity of 30 m/s strikes a curved vane, which is moving with a velocity of 15 m/s. The jet makes an angle of 30° with the direction of motion of vane at inlet and leaves at an angle of 120° to the direction of motion of vane at outlet. Calculate : (*i*) Vane angles, if the water enters and leaves the vane without shock, (*ii*) Work done per second per unit weight of water striking the vanes per second. [**Ans.** (*i*) 53° 47.7′, 15° 41′, (*ii*) 44.15 Nm/N]

11. A jet of water of diameter 50 mm, having a velocity of 30 m/s strikes a curved vane which is moving with a velocity of 15 m/s in the direction of the jet. The jet leaves the vane at an angle of 60° to the direction of motion of vanes at outlet. Determine : (*i*) the force exerted by the jet on the vane in the direction of motion, (*ii*) work done per second by the jet. [**Ans.** (*i*) 662.5 N, (*ii*) 9937.5 Nm/s]

12. A jet of water having a velocity of 20 m/s strikes a curved vane which is moving with a velocity of 9 m/s. The vane is symmetrical and is so shaped that the jet is deflected through 120°. Find the angle of the jet at inlet of the vane so that there is no shock. What is the absolute velocity of the jet at outlet in magnitude and direction and the work done per second per unit weight of water strikings ? Assume the vane to be smooth. [**Ans.** 17°, 5.95 m/s, $\beta = 79° 6'$, 18.57 Nm/N]

13. A jet of water, having a velocity of 15 m/s, strikes a curved vane which is moving with a velocity of 6 m/s in the same direction as that of the jet at inlet. The vane is so shaped that the jet is deflected through 135°. The diameter of the jet is 150 mm. Assuming the vane to be smooth, find : (*i*) the force exerted by the jet on the vane in the direction of motion, (*ii*) power of the vane, and (*iii*) efficiency of the vane. [**Ans.** (*i*) 2443.5 N, (*ii*) 14.65 kW, (*iii*) 49.16%]

14. If in the above problem, the jet of water instead of striking a single plate, strikes a series of curved vanes, find : (*i*) force exerted by the jet on the vanes in the direction the motion, (*ii*) power of the vane, and (*iii*) efficiency of the vane. [**Ans.** (*i*) 4072.5 N, (*ii*) 24.43 kW, (*iii*) 81.9%]

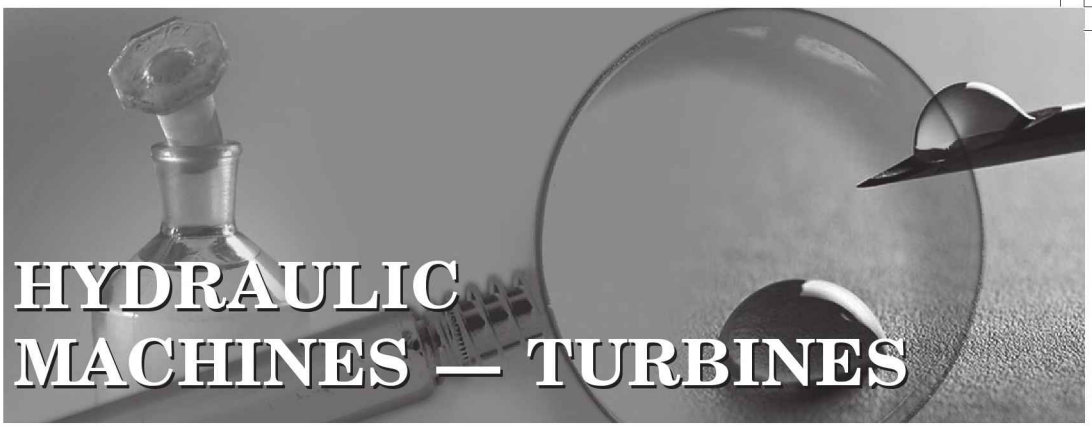
15. A jet of water having a velocity of 30 m/s, strikes a series of radial curved vanes mounted on a wheel which is rotating at 300 r.p.m. The jet makes an angle of 30° with the tangent to wheel at inlet and leaves the wheel with a velocity of 4 m/s at an angle of 120° to the tangent to the wheel at outlet. Water is flowing from outward in a radial direction. The outer and inner radii of the wheel are 0.6 m and 0.3 m respectively. Determine : (*i*) vane angles at inlet and outlet, (*ii*) work done per second per kg of water, and (*iii*) efficiency of the wheel. [**Ans.** (*i*) 42° 10.7′, 27°17.8′, (*ii*) 52.92, (*iii*) 56.5%]

16. The head of water from the centre of the orifice fitted to a tank is maintained at 6 m of water. The diameter of the orifice is 150 mm. The tank is fitted with frictionless wheels at the bottom and the tank is moving with a velocity of 4 m/s due to the reaction of the jet coming out from the orifice. Determine : (*i*) propelling force on the tank, (*ii*) work done per second, and (*iii*) efficiency of propulsion [**Ans.** (*i*) 2847.3 N, (*ii*) 11389 Nm/s, (*iii*) $\eta = 39.36\%$]

17. The water in a jet propelled boat is drawn mid-ship and is discharged at the back with an absolute velocity of 30 m/s. The cross-sectional area of the jet at the back is 0.04 m^2 and the boat is moving in sea-water with a speed of 30 km/hour. Determine : (*i*) propelling force of the boat, (*ii*) power, and (*iii*) efficiency of the jet propulsion. [**Ans.** (*i*) 45995.6 N, (*ii*) 383.14 kW, (*iii*) 34.02%]

18. The water in a jet propelled boat is drawn through inlet openings facing the direction of motion of the ship. The boat is moving in sea-water with a speed of 40 km/hr. The absolute velocity of the jet of the water discharged at the back is 40 m/s and the area of the jet of water is 0.04 m^2. Find the propelling force and efficiency of propulsion. [**Ans.** 81775.3 N, $\eta = 35.71\%$]

18 CHAPTER



HYDRAULIC MACHINES — TURBINES

▶ 18.1 INTRODUCTION

Hydraulic machines are defined as those machines which convert either hydraulic energy (energy possessed by water) into mechanical energy (which is further converted into electrical energy) or mechanical energy into hydraulic energy. The hydraulic machines, which convert the hydraulic energy into mechanical energy, are called *turbines* while the hydraulic machines which convert the mechanical energy into hydraulic energy are called *pumps*. Thus the study of hydraulic machines consists of study of turbines and pumps. Turbines consists of mainly study of Pelton turbine, Francis Turbine and Kaplan Turbine while pumps consist of study of centrifugal pump and reciprocating pumps.

▶ 18.2 TURBINES

Turbines are defined as the hydraulic machines which convert hydraulic energy into mechanical energy. This mechanical energy is used in running an electric generator which is directly coupled to the shaft of the turbine. Thus the mechanical energy is converted into electrical energy. The electric power which is obtained from the hydraulic energy (energy of water) is known as *Hydroelectric power*. At present the generation of hydroelectric power is the cheapest as compared by the power generated by other sources such as oil, coal etc.

▶ 18.3 GENERAL LAYOUT OF A HYDROELECTRIC POWER PLANT

Fig. 18.1 shows a general layout of a hydroelectric power plant which consists of :

(*i*) A dam constructed across a river to store water.

(*ii*) Pipes of large diameters called penstocks, which carry water under pressure from the storage reservoir to the turbines. These pipes are made of steel or reinforced concrete.

(*iii*) Turbines having different types of vanes fitted to the wheels.

(*iv*) Tail race, which is a channel which carries water away from the turbines after the water has worked on the turbines. The surface of water in the tail race channel is also known as tail race.

▶ 18.4 DEFINITIONS OF HEADS AND EFFICIENCIES OF A TURBINE

1. Gross Head. The difference between the head race level and tail race level when no water is flowing is known as Gross Head. It is denoted by 'H_g' in Fig. 18.1.

2. Net Head. It is also called effective head and is defined as the head available at the inlet of the turbine. When water is flowing from head race to the turbine, a loss of head due to friction between the water and penstocks occurs. Though there are other losses also such as loss due to bend, pipe fittings, loss at the entrance of penstock etc., yet they are having small magnitude as compared to head loss due to friction. If 'h_f'is the head loss due to friction between penstocks and water then net heat on turbine is given by

$$H = H_g - h_f \qquad ...(18.1)$$

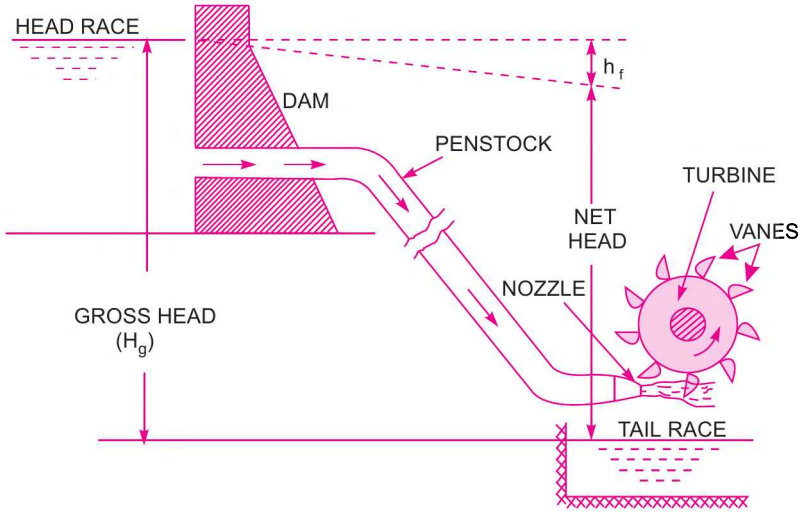


Fig. 18.1 *Layout of a hydroelectric power plant.*

where H_g = Gross head, $h_f = \dfrac{4 \times f \times L \times V^2}{D \times 2g}$,

in which V = Velocity of flow in penstock,

L = Length of penstock,

D = Diameter of penstock.

3. Efficiencies of a Turbine. The following are the important efficiencies of a turbine.

(*a*) Hydraulic Efficiency, η_h (*b*) Mechanical Efficiency, η_m

(*c*) Volumetric Efficiency, η_v and (*d*) Overall Efficiency, η_o

(*a*) **Hydraulic Efficiency (η_h).** It is defined as the ratio of power given by water to the runner of a turbine (runner is a rotating part of a turbine and on the runner vanes are fixed) to the power supplied by the water at the inlet of the turbine. The power at the inlet of the turbine is more and this power goes on decreasing as the water flows over the vanes of the turbine due to hydraulic losses as the vanes are not smooth. Hence, the power delivered to the runner of the turbine will be less than the power available at the inlet of the turbine. Thus, mathematically, the hydraulic efficiency of a turbine is written as

$$\eta_h = \frac{\text{Power delivered to runner}}{\text{Power supplied at inlet}} = \frac{\text{R.P.}}{\text{W.P.}} \qquad ...(18.2)$$

where R.P. = Power delivered to runner *i.e.*, runner power

$$= \frac{W}{g}\frac{\left[V_{w_1} \pm V_{w_2}\right] \times u}{1000} \text{ kW} \qquad \text{...for Pelton Turbine}$$

$$= \frac{W}{g}\frac{\left[V_{w_1}u_1 \pm V_{w_2}u_2\right]}{1000} \text{ kW} \qquad \text{...for a radial flow turbine}$$

W.P. = Power supplied at inlet of turbine and also called water power

$$= \frac{W \times H}{1000} \text{ kW} \qquad ...(18.3)$$

where W = Weight of water striking the vanes of the turbine per second
$= \rho g \times Q$ in which Q = Volume of water/s,
V_{w_1} = Velocity of whirl at inlet,
V_{w_2} = Velocity of whirl at outlet,
u = Tangential velocity of vane,
u_1 = Tangential velocity of vane at inlet for radial vane,
u_2 = Tangential velocity of vane at outlet for radial vane,
H = Net head on the turbine.

Power supplied at the inlet of turbine in S.I.units is known as water power. It is given by

$$\text{W.P.} = \frac{\rho \times g \times Q \times H}{1000} \text{ kW} \qquad ...(18.3A)$$

For water $\rho = 1000 \text{ kg/m}^3$

$$\therefore \quad \text{W.P.} = \frac{1000 \times g \times Q \times H}{1000} = g \times Q \times H \text{ kW} \qquad ...(18.3B)$$

The relation (18.3*B*) is only used when the flowing fluid is water. If the flowing fluid is other than the water, then relation (18.3*A*) is used.

(*b*) **Mechanical Efficiency (η_m).** The power delivered by water to the runner of a turbine is transmitted to the shaft of the turbine. Due to mechanical losses, the power available at the shaft of the turbine is less than the power delivered to the runner of a turbine. The ratio of the power available at the shaft of the turbine (known as S.P. or B.P.) to the power delivered to the runner is defined as mechanical efficiency. Hence, mathematically, it is written as

$$\eta_m = \frac{\text{Power at the shaft of the turbine}}{\text{Power delivered by water to the runner}} = \frac{\text{S.P.}}{\text{R.P.}} \qquad ...(18.4)$$

(*c*) **Volumetric Efficiency (η_v).** The volume of the water striking the runner of a turbine is slightly less than the vloume of the water supplied to the turbine. Some of the volume of the water is discharged to the tail race without striking the runner of the turbine. Thus the ratio of the volume of the water actually striking the runner to the volume of water supplied to the turbine is defined as volumetric efficiency. It is written as

$$\eta_v = \frac{\text{Volume of water actually striking the runner}}{\text{Volume of water supplied to the turbine}} \qquad ...(18.5)$$

(*d*) **Overall Efficiency (η_o).** It is defined as the ratio of power available at the shaft of the turbine to the power supplied by the water at the inlet of the turbine. It is written as :

$$\eta_o = \frac{\text{Volume available at the shaft of the turbine}}{\text{Power supplied at the inlet of the turbine}} = \frac{\text{Shaft power}}{\text{Water power}}$$

$$= \frac{\text{S.P.}}{\text{W.P.}}$$

$$= \frac{\text{S.P.}}{\text{W.P.}} \times \frac{\text{R.P.}}{\text{R.P.}} \qquad \text{(where R.P. = Power delivered to runner)}$$

$$= \frac{\text{S.P.}}{\text{R.P.}} \times \frac{\text{R.P.}}{\text{W.P.}}$$

$$= \eta_m \times \eta_h \qquad \left(\because \text{From equation (18.4)}, \frac{\text{S.P.}}{\text{R.P.}} = \eta_m \text{ and from equation (18.2)}, \frac{\text{R.P.}}{\text{W.P.}} = \eta_h \right) \qquad ...(18.6)$$

If shaft power (S.P.) is taken in kW then water power should also be taken in kW. Shaft power is commonly represented by P. But from equation (18.3*A*),

$$\text{Water power in kW} = \frac{\rho \times g \times Q \times H}{1000}, \text{ where } \rho = 1000 \text{ kg/m}^3$$

$$\therefore \quad \eta_o = \frac{\text{Shaft power in kW}}{\text{Water power in kW}} = \frac{P}{\left(\frac{\rho \times g \times Q \times H}{1000}\right)} \qquad ...(18.6A)$$

where P = Shaft power.

▶ 18.5 CLASSIFICATION OF HYDRAULIC TURBINES

The hydraulic turbines are classified according to the type of energy available at the inlet of the turbine, direction of flow through the vanes, head at the inlet of the turbine and specific speed of the turbines. Thus the following are the important classifications of the turbines :

1. According to the type of energy at inlet :
   (*a*) Impulse turbine, and (*b*) Reaction turbine.
2. According to the direction of flow through runner :
   (*a*) Tangential flow turbine, (*b*) Radial flow turbine,
   (*c*) Axial flow turbine, and (*d*) Mixed flow turbine.
3. According to the head at the inlet of turbine :
   (*a*) High head turbine, (*b*) Medium head turbine, and
   (*c*) Low head turbine.
4. According to the specific speed of the turbine :
   (*a*) Low specific speed turbine, (*b*) Medium specific speed turbine, and
   (*c*) High specific speed turbine.

If at the inlet of the turbine, the energy available is only kinetic energy, the turbine is known as **impulse turbine.** As the water flows over the vanes, the pressure is atmospheric from inlet to outlet of

the turbine. If at the inlet of the turbine, the water possesses kinetic energy as well as pressure energy, the turbine is known as **reaction turbine**. As the waters flows through the runner, the water is under pressure and the pressure energy goes on changing into kinetic energy. The runner is completely enclosed in an air-tight casing and the runner and casing is completely full of water.

If the water flows along the tangent of the runner, the turbine is known as **tangential flow turbine.** If the water flows in the radial direction through the runner, the turbine is called **radial flow turbine**. If the water flows from outwards to inwards, radially, the turbine is known as **inward** radial flow turbine, on the other hand, if water flows radially from inwards to outwards, the turbine is known as **outward** radial flow turbine. If the water flows through the runner along the direction parallel to the axis of rotation of the runner, the turbine is called **axial flow** turbine. If the water flows through the runner in the radial direction but leaves in the direction parallel to axis of rotation of the runner, the turbine is called **mixed flow** turbine.

▶ 18.6 PELTON WHEEL (OR TURBINE)

The Pelton wheel or Pelton turbine is a tangential flow impulse turbine. The water strikes the bucket along the tangent of the runner. The energy available at the inlet of the turbine is only kinetic energy. The pressure at the inlet and outlet of the turbine is atmospheric. This turbine is used for high heads and is named after L.A. Pelton, an American Engineer.

Fig. 18.1 shows the layout of a hydroelectric power plant in which the turbine is Pelton wheel . The water from the reservoir flows through the penstocks at the outlet of which a nozzle is fitted. The nozzle increases the kinetic energy of the water flowing through the penstock. At the outlet of the nozzle, the water comes out in the form of a jet and strikes the buckets (vanes) of the runner. The main parts of the Pelton turbine are :

1. Nozzle and flow regulating arrangement (spear),
2. Runner and buckets,
3. Casing, and
4. Breaking jet.

1. Nozzle and Flow Regulating Arrangement. The amount of water striking the buckets (vanes) of the runner is controlled by providing a spear in the nozzle as shown in Fig. 18.2. The spear is a conical needle which is operated either by a hand wheel or automatically in an axial direction depending upon the size of the unit. When the spear is pushed forward into the nozzle the amount of water striking the runner is reduced. On the other hand, if the spear is pushed back, the amount of water striking the runner increases.

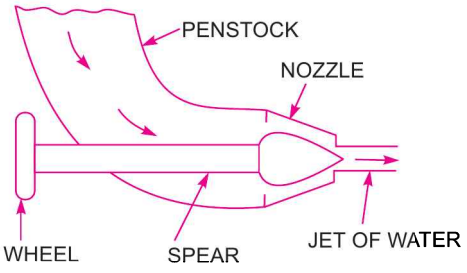

Fig. 18.2 *Nozzle with a spear to regulate flow.*

2. Runner with Buckets. Fig. 18.3 shows the runner of a Pelton wheel. It consists of a circular disc on the periphery of which a number of buckets evenly spaced are fixed. The shape of the buckets is of a double hemispherical cup or bowl. Each bucket is divided into two symmetrical parts by a dividing wall which is known as splitter.

The jet of water strikes on the splitter. The splitter divides the jet into two equal parts and the jet comes out at the outer edge of the bucket. The buckets are shaped in such a way that the jet gets deflected through 160° or 170°. The buckets are made of cast iron, cast steel bronze or stainless steel depending upon the head at the inlet of the turbine.

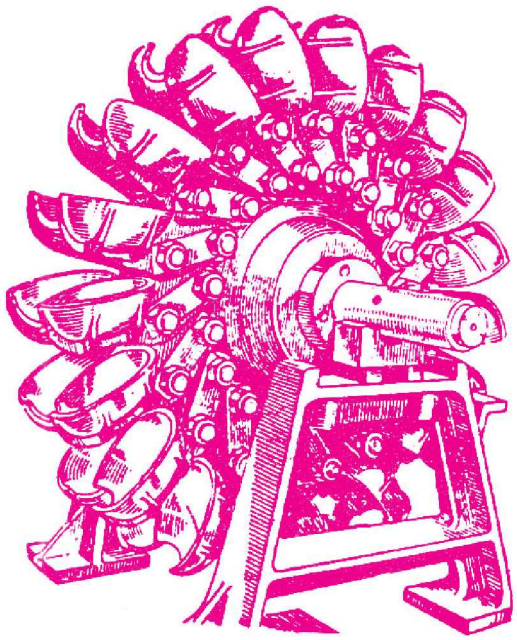

Fig. 18.3 *Runner of a pelton wheel.*

3. Casing. Fig. 18.4 shows a Pelton turbine with a casing. The function of the casing is to prevent the splashing of the water and to discharge water to tail race. It also acts as safeguard against accidents. It is made of cast iron or fabricated steel plates. The casing of the Pelton wheel does not perform any hydraulic function.

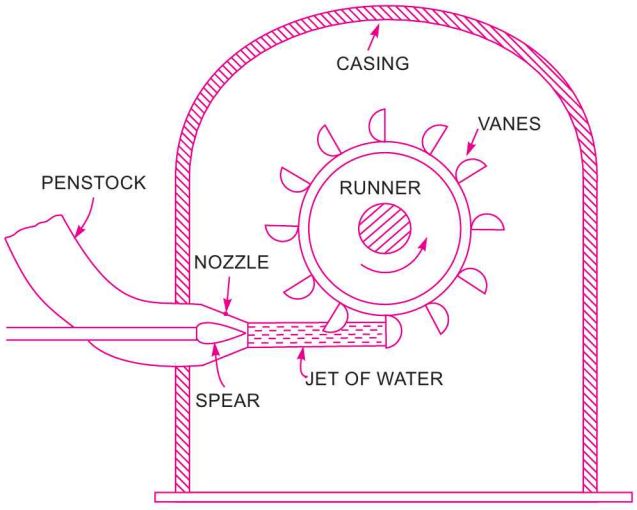

Fig. 18.4 *Pelton turbine.*

4. Breaking Jet. When the nozzle is completely closed by moving the spear in the forward direction, the amount of water striking the runner reduces to zero. But the runner due to inertia goes on revolving for a long time. To stop the runner in a short time, a small nozzle is provided which directs the jet of water on the back of the vanes. This jet of water is called breaking jet.

18.6.1 Velocity Triangles and Work done for Pelton Wheel. Fig. 18.5 shows the shape of the vanes or buckets of the Pelton wheel. The jet of water from the nozzle strikes the bucket at the splitter, which splits up the jet into two parts. These parts of the jet, glides over the inner surfaces and comes out at the outer edge. Fig. 18.5 (*b*) shows the section of the bucket at *Z-Z*. The splitter is the inlet tip and outer edge of the bucket is the outlet tip of the bucket. The inlet velocity triangle is drawn at the splitter and outlet velocity triangle is drawn at the outer edge of the bucket, by the same method as explained in Chapter 17.

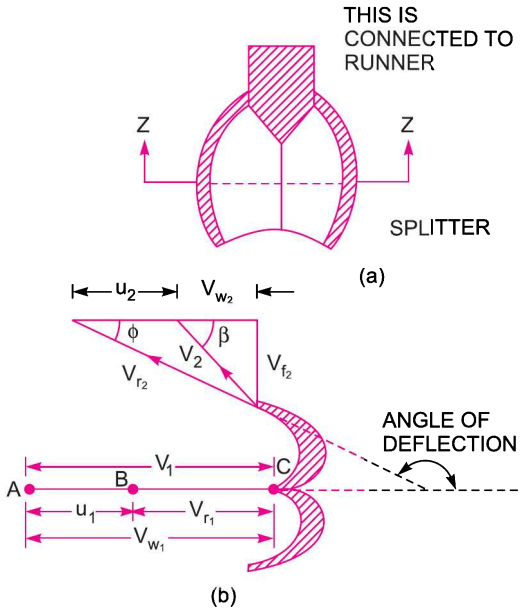

Fig. 18.5 *Shape of bucket.*

Let H = Net head acting on the Pelton wheel
$= H_g - h_f$

where H_g = Gross head and $h_f = \dfrac{4fLV^2}{D^* \times 2g}$

where D^* = Dia. of Penstock, N = Speed of the wheel in r.p.m.,
D = Diameter of the wheel, d = Diameter of the jet.

Then V_1 = Velocity of jet at inlet = $\sqrt{2gH}$ ...(18.7)

$$u = u_1 = u_2 = \frac{\pi DN}{60}.$$

The velocity triangle at inlet will be a straight line where

$$V_{r_1} = V_1 - u_1 = V_1 - u$$

$$V_{w_1} = V_1$$

$$\alpha = 0^\circ \text{ and } \theta = 0^\circ$$

From the velocity triangle at outlet, we have

$$V_{r_2} = V_{r_1} \text{ and } V_{w_2} = V_{r_2} \cos \phi - u_2.$$

The force exerted by the jet of water in the direction of motion is given by equation (17.19) as

$$F_x = \rho a V_1 [V_{w_1} + V_{w_2}] \quad ...(18.8)$$

As the angle β is an acute angle, +ve sign should be taken. Also this is the case of series of vanes, the mass of water striking is $\rho a V_1$ and not $\rho a V_{r_1}$. In equation (18.8), 'a' is the area of the jet which is given as

$$a = \text{Area of jet} = \frac{\pi}{4} d^2.$$

Now work done by the jet on the runner per second

$$= F_x \times u = \rho a V_1 [V_{w_1} + V_{w_2}] \times u \text{ Nm/s} \quad ...(18.9)$$

Power given to the runner by the jet

$$= \frac{\rho a V_1 \left[V_{w_1} + V_{w_2}\right] \times u}{1000} \text{ kW} \quad ...(18.10)$$

Work done/s per unit weight of water striking/s

$$= \frac{\rho a V_1 \left[V_{w_1} + V_{w_2}\right] \times u}{\text{Weight of water striking/s}}$$

$$= \frac{\rho a V_1 \left[V_{w_1} + V_{w_2}\right] \times u}{\rho a V_1 \times g} = \frac{1}{g} \left[V_{w_1} + V_{w_2}\right] \times u \quad ...(18.11)$$

The energy supplied to the jet at inlet is in the form of kinetic energy and is equal to $\frac{1}{2} m V^2$

$\therefore$ K.E. of jet per second $= \frac{1}{2} (\rho a V_1) \times V_1^2$

$\therefore$ **Hydraulic efficiency**, $\eta_h = \frac{\text{Work done per second}}{\text{K.E. of jet per second}}$

$$= \frac{\rho a V_1 \left[V_{w_1} + V_{w_2}\right] \times u}{\frac{1}{2} (\rho a V_1) \times V_1^2} = \frac{2 \left[V_{w_1} + V_{w_2}\right] \times u}{V_1^2} \quad ...(18.12)$$

Now $V_{w_1} = V_1$, $V_{r_1} = V_1 - u_1 = (V_1 - u)$

$\therefore$ $V_{r_2} = (V_1 - u)$

and $V_{w_2} = V_{r_2} \cos \phi - u_2 = V_{r_2} \cos \phi - u = (V_1 - u) \cos \phi - u$

Substituting the values of V_{w_1} and V_{w_2} in equation (18.12),

$$\eta_h = \frac{2 \left[V_1 + (V_1 - u) \cos \phi - u\right] \times u}{V_1^2}$$

$$= \frac{2 \left[V_1 - u + (V_1 - u) \cos \phi\right] \times u}{V_1^2} = \frac{2 (V_1 - u) [1 + \cos \phi] u}{V_1^2}. \quad ...(18.13)$$

The efficiency will be maximum for a given value of V_1 when

$$\frac{d}{du}(\eta_h) = 0 \quad \text{or} \quad \frac{d}{du}\left[\frac{2u(V_1 - u)(1 + \cos\phi)}{V_1^2}\right] = 0$$

or $$\frac{(1+\cos\phi)}{V_1^2}\frac{d}{du}(2uV_1 - 2u^2) = 0 \quad \text{or} \quad \frac{d}{du}[2uV_1 - 2u^2] = 0 \quad \left(\because \frac{1+\cos\phi}{V_1^2} \neq 0\right)$$

or $$2V_1 - 4u = 0 \quad \text{or} \quad u = \frac{V_1}{2} \qquad ...(18.14)$$

Equation (18.14) states that hydraulic efficiency of a Pelton wheel will be maximum when the velocity of the wheel is half the velocity of the jet of water at inlet. The expression for maximum efficiency will be obtained by substituting the value of $u = \frac{V_1}{2}$ in equation (18.13).

$$\therefore \quad \text{Max. } \eta_h = \frac{2\left(V_1 - \frac{V_1}{2}\right)(1+\cos\phi) \times \frac{V_1}{2}}{V_1^2}$$

$$= \frac{2 \times \frac{V_1}{2}(1+\cos\phi)\frac{V_1}{2}}{V_1^2} = \frac{(1+\cos\phi)}{2}. \qquad ...(18.15)$$

18.6.2 Points to be Remembered for Pelton Wheel

(*i*) The velocity of the jet at inlet is given by $V_1 = C_v\sqrt{2gH}$

where C_v = Co-efficient of velocity = 0.98 or 0.99

H = Net head on turbine

(*ii*) The velocity of wheel (u) is given by $u = \phi\sqrt{2gH}$

where ϕ = Speed ratio. The value of speed ratio varies from 0.43 to 0.48.

(*iii*) The angle of deflection of the jet through buckets is taken at 165° if no angle of deflection is given.

(*iv*) The mean diameter or the pitch diameter D of the Pelton wheel is given by

$$u = \frac{\pi DN}{60} \text{ or } D = \frac{60u}{\pi N}.$$

(*v*) **Jet Ratio.** It is defined as the ratio of the pitch diameter (D) of the Pelton wheel to the diameter of the jet (d). It is denoted by 'm' and is given as

$$m = \frac{D}{d} \text{ (= 12 for most cases)} \qquad ...(18.16)$$

(*vi*) Number of buckets on a runner is given by

$$Z = 15 + \frac{D}{2d} = 15 + 0.5\text{ m} \qquad ...(18.17)$$

where m = Jet ratio

(*vii*) **Number of Jets.** It is obtained by dividing the total rate of flow through the turbine by the rate of flow of water through a single jet.

Problem 18.1 *A Pelton wheel has a mean bucket speed of 10 metres per second with a jet of water flowing at the rate of 700 litres/s under a head of 30 metres. The buckets deflect the jet through an angle of 160°. Calculate the power given by water to the runner and the hydraulic efficiency of the turbine. Assume co-efficient of velocity as 0.98.*

Solution. Given :

Speed of bucket, $u = u_1 = u_2 = 10$ m/s

Discharge, $Q = 700$ litres/s $= 0.7$ m^3/s, Head of water, $H = 30$ m

Angle of deflection $= 160°$

$\therefore$ Angle, $\phi = 180° - 160° = 20°$

Co-efficient of velocity, $C_v = 0.98$.

The velocity of jet, $V_1 = C_v\sqrt{2gH} = 0.98\ \sqrt{2 \times 9.81 \times 30} = 23.77$ m/s

$\therefore$ $V_{r_1} = V_1 - u_1 = 23.77 - 10$

$= 13.77$ m/s

$V_{w_1} = V_1 = 23.77$ m/s

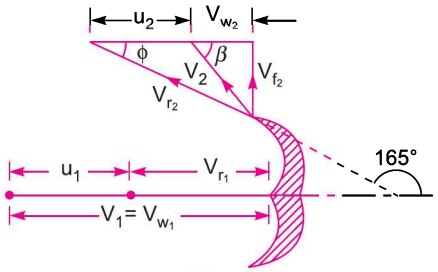

Fig. 18.6

From outlet velocity triangle,

$V_{r_2} = V_{r_1} = 13.77$ m/s

$V_{w_2} = V_{r_2} \cos \phi - u_2$

$= 13.77 \cos 20° - 10.0 = 2.94$ m/s

Work done by the jet per second on the runner is given by equation (18.9) as

$= \rho a V_1 \left[V_{w_1} + V_{w_2}\right] \times u$

$= 1000 \times 0.7 \times [23.77 + 2.94] \times 10$ ($\because$ $aV_1 = Q = 0.7$ m^3/s)

$= 186970$ Nm/s

$\therefore$ Power given to turbine $= \dfrac{186970}{1000} =$ **186.97 kW. Ans.**

The hydraulic efficiency of the turbine is given by equation (18.12) as

$$\eta_h = \frac{2\left[V_{w_1} + V_{w_2}\right] \times u}{V_1^2} = \frac{2[23.77 + 2.94] \times 10}{23.77 \times 23.77}$$

$=$ **0.9454** or **94.54%. Ans.**

Problem 18.2 *A Pelton wheel is to be designed for the following specifications :*
Shaft power = 11,772 kW ; Head = 380 metres ; Speed = 750 r.p.m. ; Overall efficiency = 86% ; Jet diameter is not to exceed one-sixth of the wheel diameter. Determine :

(i) The wheel diameter, (ii) The number of jets required, and
(iii) Diameter of the jet.

Take $K_{v_1} = 0.985$ and $K_{u_1} = 0.45$

Solution. Given :

Shaft power, S.P. $= 11{,}772$ kW

Head , $H = 380$ m

Speed, $N = 750$ r.p.m.

Overall efficiency, $\eta_0 = 86\%$ or 0.86

Ratio of jet dia. to wheel dia. $= \frac{d}{D} = \frac{1}{6}$

Co-efficient of velocity, $K_{v_1} = C_v = 0.985$

Speed ratio, $K_{u_1} = 0.45$

Velocity of jet, $V_1 = C_v\sqrt{2gH} = 0.985\sqrt{2 \times 9.81 \times 380} = 85.05$ m/s

The velocity of wheel, $u = u_1 = u_2$

$= \text{Speed ratio} \times \sqrt{2gH} = 0.45 \times \sqrt{2 \times 9.81 \times 380} = 38.85$ m/s

But $u = \frac{\pi DN}{60} \quad \therefore \quad 38.85 = \frac{\pi DN}{60}$

or $D = \frac{60 \times 38.85}{\pi \times N} = \frac{60 \times 38.85}{\pi \times 750} =$ **0.989 m. Ans.**

But $\frac{d}{D} = \frac{1}{6}$

$\therefore$ Dia. of jet, $d = \frac{1}{6} \times D = \frac{0.989}{6} =$ **0.165 m. Ans.**

Discharge of one jet, $q =$ Area of jet $\times$ Velocity of jet

$= \frac{\pi}{4} d^2 \times V_1 = \frac{\pi}{4}(.165) \times 85.05 \text{ m}^3/\text{s} = 1.818 \text{ m}^3/\text{s}$ ...(*i*)

Now $\eta_o = \frac{\text{S.P.}}{\text{W.P.}} = \frac{11772}{\frac{\rho g \times Q \times H}{1000}}$

$0.86 = \frac{11772 \times 1000}{1000 \times 9.81 \times Q \times 380}$, where Q = Total discharge

$\therefore$ Total discharge, $Q = \frac{11772 \times 1000}{1000 \times 9.81 \times 380 \times 0.86} = 3.672 \text{ m}^3/\text{s}$

$\therefore$ Number of jets $= \frac{\text{Total discharge}}{\text{Discharge of one jet}} = \frac{Q}{q} = \frac{3.672}{1.818} =$ **2 jets. Ans.**

Problem 18.3 *The penstock supplies water from a reservoir to the Pelton wheel with a gross head of 500 m. One third of the gross head is lost in friction in the penstock. The rate of flow of water through the nozzle fitted at the end of the penstock is 2.0 m^3/s. The angle of deflection of the jet is 165°. Determine the power given by the water to the runner and also hydraulic efficiency of the Pelton wheel. Take speed ratio = 0.45 and C_v = 1.0.*

Solution. Given :

Gross head, $H_g = 500$ m

Head lost in friction, $h_f = \frac{H_g}{3} = \frac{500}{3} = 166.7$ m

$\therefore$ Net head, $H = H_g - h_f = 500 - 166.7 = 333.30$ m

Discharge, $Q = 2.0$ m^3/s

Angle of deflection $= 165°$

$\therefore$ Angle, $\phi = 180° - 165° = 15°$

Speed ratio $= 0.45$

Co-efficient of velocity, $C_v = 1.0$

Velocity of jet, $V_1 = C_v\sqrt{2gH} = 1.0 \times \sqrt{2 \times 9.81 \times 333.3} = 80.86$ m/s

Velocity of wheel, $u =$ Speed ratio $\times \sqrt{2gH}$

or $u = u_1 = u_2 = 0.45 \times \sqrt{2 \times 9.81 \times 333.3} = 36.387$ m/s

$\therefore$ $V_{r_1} = V_1 - u_1 = 80.86 - 36.387$

$= 44.473$ m/s

Also $V_{w_1} = V_1 = 80.86$ m/s

From outlet velocity triangle, we have

$V_{r_2} = V_{r_1} = 44.473$

$V_{r_2} \cos \phi = u_2 + V_{w_2}$

or $44.473 \cos 15° = 36.387 + V_{w_2}$

or $V_{w_2} = 44.473 \cos 15° - 36.387 = 6.57$ m/s.

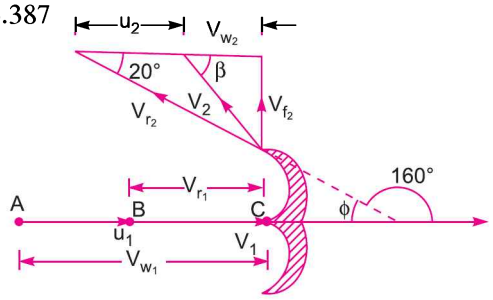

Fig. 18.7

Work done by the jet on the runner per second is given by equation (18.9) as

$$\rho a V_1 [V_{w_1} + V_{w_2}] \times u = \rho Q [V_{w_1} + V_{w_2}] \times u \qquad (\because \ aV_1 = Q)$$

$$= 1000 \times 2.0 \times [80.86 + 6.57] \times 36.387 = 6362630 \text{ Nm/s}$$

$\therefore$ Power given by the water to the runner in kW

$$= \frac{\text{Work done per second}}{1000} = \frac{6362630}{1000} = \mathbf{6362.63 \text{ kW. Ans.}}$$

Hydraulic efficiency of the turbine is given by equation (18.12) as

$$\eta_h = \frac{2\left[V_{w_1} + V_{w_2}\right] \times u}{V_1^2} = \frac{2[80.86 + 6.57] \times 36.387}{80.86 \times 80.86}$$

$= \mathbf{0.9731}$ or $\mathbf{97.31\%}$**. Ans.**

Problem 18.4 *A Pelton wheel is having a mean bucket diameter of 1 m and is running at 1000 r.p.m. The net head on the Pelton wheel is 700 m. If the side clearance angle is 15° and discharge through nozzle is 0.1 m^3/s, find :*

(i) Power available at the nozzle, and (ii) Hydraulic efficiency of the turbine.

Solution. Given :

Diameter of wheel, $D = 1.0$ m

Speed of wheel, $N = 1000$ r.p.m.

$\therefore$ Tangential velocity of the wheel, $u = \frac{\pi DN}{60} = \frac{\pi \times 1.0 \times 1000}{60} = 52.36$ m/s

Net head on turbine $H = 700$ m

Side clearance angle, $\phi = 15°$

Discharge, $Q = 0.1\ m^3/s$

Velocity of jet at inlet, $V_1 = C_v\sqrt{2gH} = 1 \times \sqrt{2 \times 9.81 \times 700}$

($\because$ Value of C_v is not given. Take it = 1.0)

or $V_1 = 117.19$ m/s

(*i*) Power available at the nozzle is given by equation (18.3) as

$$\text{W.P.} = \frac{W \times H}{1000} = \frac{\rho \times g \times Q \times H}{1000}$$

$$= \frac{1000 \times 9.81 \times 0.1 \times 700}{1000} = \textbf{686.7 kW. Ans.}$$

(*ii*) Hydraulic efficiency is given by equation (18.13) as

$$\eta_h = \frac{2(V_1 - u)(1 + \cos\phi)\, u}{V_1^2}$$

$$= \frac{2(117.19 - 52.36)(1 + \cos 15^\circ) \times 52.36}{117.19 \times 117.19}$$

$$= \frac{2 \times 64.83 \times 1.966 \times 52.36}{117.19 \times 117.19} = 0.9718 = \textbf{97.18 \%. Ans.}$$

Problem 18.5 *A Pelton wheel is working under a gross head of 400 m. The water is supplied through penstock of diameter 1 m and length 4 km from reservoir to the Pelton wheel. The co-efficient of friction for the penstock is given as .008. The jet of water of diameter 150 mm strikes the buckets of the wheel and gets deflected through an angle of 165°. The relative velocity of water at outlet is reduced by 15% due to friction between inside surface of the bucket and water. If the velocity of the buckets is 0.45 times the jet velocity at inlet and mechanical efficiency as 85% determine :*

(i) Power given to the runner, (ii) Shaft power,

(iii) Hydraulic efficiency and overall efficiency.

Solution. Given :

Gross head, $H_g = 400$ m

Diameter of penstock, $D = 1.0$ m

Length of penstock, $L = 4$ km $= 4 \times 1000 = 4000$ m

Co-efficient of friction, $f = .008$

Diameter of jet, $d = 150$ mm $= 0.15$ m

Angle of deflection $= 165°$

$\therefore$ Angle, $\phi = 180° - 165° = 15°$

Relative velocity at outlet, $V_{r_2} = 0.85\ V_{r_1}$

Velocity of bucket, $u = 0.45 \times$ Jet velocity

Mechanical efficiency, $\eta_m = 85\% = 0.85$

Let V^* = Velocity of water in penstock, and

V_1 = Velocity of jet of water.

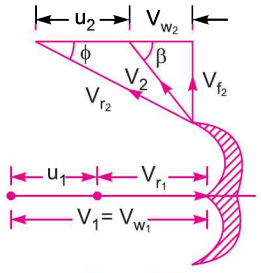

Fig. 18.8

Using continuity equation, we have

Area of penstock × V^* = Area of jet × V_1

or $$\frac{\pi}{4}D^2 \times V^* = \frac{\pi}{4}d^2 \times V_1$$

$$\therefore \quad V^* = \frac{d^2}{D^2} \times V_1 = \frac{0.15^2}{1.0^2} \times V_1 = .0225\ V_1 \qquad ...(i)$$

Applying Bernoulli's equation to the free surface of water in the reservoir and outlet of the nozzle, we get

$$H_g = \text{Head lost due to friction} + \frac{V_1^2}{2g}$$

or $$400 = \frac{4fLV^{*2}}{D \times 2g} + \frac{V_1^2}{2g} = \frac{4 \times .008 \times 4000 \times V^{*2}}{1.0 \times 2 \times 9.81} + \frac{V_1^2}{2g}$$

Substituting the value of V^* from equation (i), we get

$$400 = \frac{4 \times .008 \times 4000}{2 \times 9.81} \times (0.0225\ V_1)^2 + \frac{V_1^2}{2g}$$

$$= .0033\ V_1^2 + .051\ V_1^2 \text{ or } 400 = .0543\ V_1^2$$

$$\therefore \quad V_1 = \sqrt{\frac{400}{.0543}} = 85.83 \text{ m/s.}$$

Now velocity of bucket, $u_1 = 0.45\ V_1 = 0.45 \times 85.83 = 38.62$ m/s

From inlet velocity triangle, $V_{r_1} = V_1 - u_1 = 85.83 - 38.62 = 47.21$ m/s

$$V_{w_1} = V_1 = 85.83 \text{ m/s}$$

From outlet velocity triangle, $V_{r_2} = 0.85 \times V_{r_1} = 0.85 \times 47.21 = 40.13$ m/s

$$V_{w_2} = V_{r_2} \cos \phi - u_2 = 40.13 \cos 15° - 38.62$$

$$= 0.143 \text{ m/s} \qquad (\because \quad u = u_1 = u_2 = 38.62)$$

Discharge through nozzle is given as

$$Q = \text{Area of jet} \times \text{Velocity of jet} = a \times V_1$$

$$= \frac{\pi}{4}d^2 \times V_1 = \frac{\pi}{4}(.15)^2 \times 85.83 = 1.516 \text{ m}^3\text{/s}$$

Work done on the wheel per second is given by equation (18.9) as

$$= \rho a V_1 [V_{w_1} + V_{w_2}] \times u = \rho Q \left[V_{w_1} + V_{w_2}\right] \times u$$

$$= 1000 \times 1.516\ [85.83 + .143] \times 38.62 = 5033540 \text{ Nm/s}$$

(i) Power given to the runner in kW

$$= \frac{\text{Work done per second}}{1000} = \frac{5033540}{1000} = \mathbf{5033.54\ kW.\ Ans.}$$

(*ii*) Using equation (18.4) for mechanical efficiency,

$$\eta_m = \frac{\text{Power at the shaft}}{\text{Power given to the runner}} = \frac{\text{S.P.}}{5033.54}$$

$\therefore$ S.P. $= \eta_m \times 5033.54 = 0.85 \times 5033.54 =$ **4278.5 kW. Ans.**

(*iii*) Hydraulic efficiency is given by equation (18.12) as

$$\eta_h = \frac{2\left[V_{w_1} + V_{w_2}\right] \times u}{V_1^2}$$

$$= \frac{2\,[85.83 + .143] \times 38.62}{85.83 \times 85.83} = 0.9014 = \textbf{90.14\%. Ans.}$$

Overall efficiency is given by equation (18.6) as

$$\eta_0 = \eta_m \times \eta_h = 0.85 \times .9014 = 0.7662 \text{ or } \textbf{76.62\%. Ans.}$$

Problem 18.6 *A Pelton wheel nozzle, for which $C_v = 0.97$, is 400 m below the water surface of a lake. The jet diameter is 80 mm, the pipe diameter is 0.6 m, its length is 4 km and $f = 0.032$ in the formula $h_f = \dfrac{fLV^2}{2g \times D}$. The buckets, deflect the jet through 165° and they run at 0.48 times the jet speed, bucket friction reducing the relative velocity at outlet by 15% of the relative velocity at inlet. Mechanical efficiency = 90%. Find the flow rate and the shaft power developed by the turbine.*

Solution. Given :

$C_v = 0.97$

Gross head, $H_g = 400$ m

Dia. of jet, $d = 800 \text{ mm} = \dfrac{80}{1000}$ m

$= .08$ m

Dia. of pipe, $D = 0.6$ m

Length of pipe $L = 4 \text{ km} = 4000$ m

$f = .032$

Angle, $\phi = 180° - 165° = 15°$

Bucket speed, $u = 0.48$ times jet speed

Relative velocity at outlet $= 0.85$ times relative velocity at inlet

or $V_{r_2} = 0.85\ V_{r_1}$

Mechanical efficiency, $\eta_m = 0.90$.

Find. (*i*) Flow rate, and (*ii*) Shaft power, S.P.

Let V = Velocity of water in pipe, and

V_1 = Velocity of jet of water.

From continuity equation, we have

Area of pipe $\times V$ = Area of jet $\times V_1$

or $$\frac{\pi}{4}D^2 \times V = \frac{\pi}{4}d^2 \times V_1$$

$$= \frac{d^2}{D^2} \times V_1 = \left(\frac{.08}{0.60}\right)^2 \times V_1 = 0.0177\ V_1 \qquad ...(i)$$

Applying Bernoulli's equation to the free surface of water in the reservoir and the outlet of the nozzle, we get

Head at reservoir = Kinetic head of jet of water + Head lost due to friction in pipe + Head lost in nozzle

$$= \frac{V_1^2}{2g} + \frac{fLV^2}{D \times 2g} + \text{Head lost in nozzle} \qquad ...(ii)$$

Let V* = Theoretical velocity at the outlet of nozzle, V_1 = Actual velocity of jet of water

Then $$\frac{V_1}{V^*} = C_v \text{ or } V^* = \frac{V_1}{C_v}.$$

Now head lost in nozzle = Head corresponding to V^* – Head corresponding to V_1

$$= \frac{V^{*2}}{2g} - \frac{V_1^2}{2g} = \left(\frac{V_1}{C_v}\right)^2 \times \frac{1}{2g} - \frac{V_1^2}{2g} = \frac{V_1^2}{2g}\left(\frac{1}{C_v^2} - 1\right)$$

Substituting this value in equation (*ii*), we get

Head at reservoir $$= \frac{V_1^2}{2g} + \frac{fLV^2}{2g \times D} + \frac{V_1^2}{2g}\left(\frac{1}{C_v^2} - 1\right)$$

or $$400 = \frac{V_1^2}{2g} + \frac{0.032 \times 4000 \times V^2}{0.6 \times 2 \times 9.81} + \frac{V_1^2}{2g} \times \frac{1}{C_v^2} - \frac{V_1^2}{2g}$$

$$= \frac{0.032 \times 4000 \times (.0177 V_1)^2}{0.6 \times 2 \times 9.81} + \frac{V_1^2}{2 \times 9.81} \times \frac{1}{.97^2}$$

$$= .0034\ V_1^2 + .054\ V_1^2 \qquad (\because\ V = .0177\ V_1)$$

$$= 0.0574\ V_1^2$$

$\therefore$ $$V_1 = \sqrt{\frac{400}{.0574}} = 83.47 \text{ m/s}$$

Now velocity of bucket, $u_1 = 0.48 \times V_1 = 0.48 \times 83.47 = 40.06$ m/s

Refer to Fig. 18.8 (*a*), we have from inlet velocity triangle

$$V_{r_1} = V_1 - u_1 = 83.47 - 40.06 = 43.41 \text{ m/s}$$

$$V_{w_1} = V_1 = 83.47$$

From outlet velocity triangle,

$$V_{r_2} = 0.85\ V_{r_1} = 0.85 \times 43.41 = 36.898 \text{ m/s}$$

$$V_{w_2} = u_2 - V_{r_2} \cos \phi$$

$$= 40.06 - 36.898 \times \cos 15°$$

$$(\because\ u_1 = u_2 = 40.06)$$

$$= 4.42$$

Flow rate, Q = Area of jet × Velocity of jet

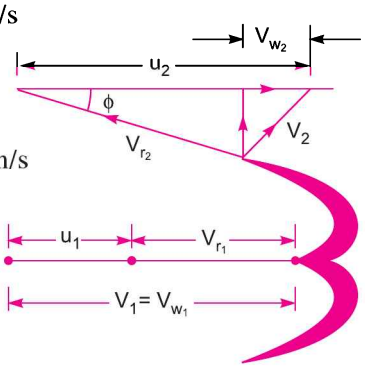

Fig. 18.8 (*a*)

$$= \frac{\pi}{4} d^2 \times V_1 = \frac{\pi}{4}(.08)^2 \times 83.47 = \mathbf{0.419\ m^3/s.\ Ans.}$$

Now using equation (18.4), $\eta_m = \dfrac{\text{S.P.}}{\text{Power given to the runner}}$

$\therefore$ S.P. $= \eta_m \times$ Power given to the runner

where power given to the runner in kW

$$= \frac{\text{Work done per second}}{1000}$$

Work done per second $= \dfrac{W}{g}\left[V_{w_1} - V_{w_2}\right] \times u$

(Here –ve sign is taken as V_{w_1} and V_{w_2} are in the same direction)

$$= \frac{\rho \times g \times Q}{g}[V_{w_1} - V_{w_2}] \times u_1 \qquad \{\because \quad u = u_1\}$$

$$= \frac{1000 \times 9.81 \times .419}{9.81}\ [83.47 - 4.42] \times 40.06 = 1326865\ \text{Nm/s}$$

$\therefore$ Power given to the runner $= \dfrac{1326865}{1000} = 1326.865$ kW

$\therefore$ S.P. $= \eta_m \times$ Power given to runner

$= 0.90 \times 1326.865 =$ **1194.18 kW. Ans.**

Problem 18.7 *A 137 mm diameter jet of water issuing from a nozzle impinges on the buckets of a Pelton wheel and the jet is deflected through an angle of 165° by the buckets. The head available at the nozzle is 400 m. Assuming co-efficient of velocity as 0.97, speed ratio as 0.46, and reduction in relative velocity while passing through buckets as 15%, find :*

(i) The force exerted by the jet on buckets in tangential direction,

(ii) The power developed.

Solution. Given :

Dia. of jet, $d = 137$ mm $= 0.137$ m

$\therefore$ Area of jet, $a = \dfrac{\pi}{4} \times 0.137 = 0.01474\ \text{m}^2$

Angle of deflection $= 165°$

$\therefore$ Angle, $\phi = 180° - 165° = 15°$

Head of water, $H = 400$ m

Co-efficient of velocity, $C_v = 0.97$

Speed ratio $= 0.46$

Relative velocity at outlet $= 0.85 \times$ relative velocity at inlet

or $V_{r_2} = 0.85\ V_{r_1}$

Now velocity of jet, $V_1 = C_v\sqrt{2gH} = 0.97\sqrt{2 \times 9.81 \times 400} = 85.93$ m/s

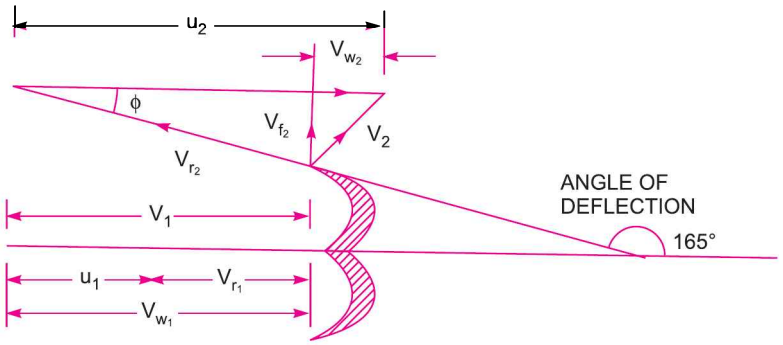

Fig. 18.8 (*b*)

Speed ratio $= \dfrac{u_1}{\sqrt{2gH}}$ or $0.46 = \dfrac{u_1}{\sqrt{2 \times 9.81 \times 400}}$

$\therefore \quad u_1 = 0.46 \times \sqrt{2 \times 9.81 \times 400} = 40.75$ m/s

Hence $V_{r_1} = V_1 - u_1 = 85.93 - 40.75 = 45.18$ m/s

and $V_{r_2} = 0.85\ V_{r_1} = 0.85 \times 45.18 = 38.40$ m/s

For Pelton turbine, $u_1 = u_2 = u = 40.75$ m/s

$V_{r_2} \cos \phi = 38.40 \times \cos 15° = 37.092$

Here $V_{r_2} \cos \phi$ is less than u_2. Hence velocity triangle at outlet will be as shown in Fig. 18.8 (*b*)

$\therefore \quad V_{w_2} = u_2 - V_{r_2} \cos \phi = 40.75 - 37.092 = 3.658$ m/s.

(*i*) Force exerted by jet on buckets in tangential direction is given by,

$$F_x = \rho a V_1 [V_{w_1} - V_{w_2}]$$

(Here –ve sign is taken as V_{w_1} and V_{w_2} are in the same direction)

$\therefore \quad F_x = 1000 \times 0.01474 \times 85.93\ (85.93 - 3.658)$ N = **104206 N. Ans.**

(*ii*) Power developed is given by,

$$\text{Power} = \frac{F_x \times u}{1000} \text{ kW} = \frac{104206 \times 40.75}{1000} = \textbf{4246.4 kW. Ans.}$$

Problem 18.8 *Two jets strike the buckets of a Pelton wheel, which is having shaft power as 15450 kW. The diameter of each jet is given as 200 mm. If the net head on the turbine is 400 m, find the overall efficiency of the turbine. Take $C_v = 1.0$.*

Solution. Given :

Number of jets $= 2$

Shaft power, S.P. $= 15450$ kW

Diameter of each jet, $d = 200$ mm $= 0.20$ m

$\therefore$ Area of each jet, $a = \dfrac{\pi}{4} d^2 = \dfrac{\pi}{4} (.2)^2 = 0.031416$ m^2

Net head, $H = 400$ m

Co-efficient of velocity, $C_v = 1.0$

Velocity of each jet, $V_1 = C_v\sqrt{2gH} = 1.0 \times \sqrt{2 \times 9.81 \times 400} = 88.58$ m/s

Discharge of each jet $= a \times V_1 = .031416 \times 88.58 = 2.78$ m^3/s

$\therefore$ Total discharge, $Q = 2 \times 2.78 = 5.56$ m^3/s

Power at the inlet of turbine,

$$\text{W.P.} = \frac{\rho \times g \times Q \times H}{1000} \text{ kW}$$

$$= \frac{1000 \times 9.81 \times 5.56 \times 400}{1000} = 21817.44 \text{ kW}$$

$\therefore$ Overall efficiency is given as

$$\eta_o = \frac{\text{S.P.}}{\text{W.P.}} = \frac{15450}{21817.44} = 0.708 = \mathbf{70.8\%}. \textbf{ Ans.}$$

Problem 18.9 *The water available for a Pelton wheel is 4 cumec and the total head from the reservoir to the nozzle is 250 metres. The turbine has two runners with two jets per runner. All the four jets have the same diameters. The pipe line is 3000 metres long. The efficiency of power transmission through the pipe line and the nozzle is 91% and efficiency of each runner is 90%. The velocity co-efficient of each nozzle is 0.975 and co-efficient of friction '4f' for the pipe is 0.0045. Determine :*

(i) The power developed by the turbine, (ii) The diameter of the jet, and

(iii) The diameter of the pipe line.

Solution. Given :

Total discharge, $Q = 4$ cumec $= 4.0$ m^3/s

Total or gross head, $H_g = 250$ m

Total number of jets $= 2 \times 2 = 4$

Length of pipe, $L = 3000$ m

Efficiency of the pipe line and nozzle = 91% or 0.91

Efficiency of runner* or $\eta_h = 90\%$ or 0.90

Co-efficient of velocity, $C_v = 0.975$

Co-efficient of friction, $4f = .0045$

Efficiency of power transmission through pipe lines and nozzle is given by

$$\eta = \frac{H_g - h_f}{H_g} \text{ or } 0.91 = \frac{250 - h_f}{250}$$

where h_f = Head lost due to friction.

$\therefore$ $h_f = 250 - 0.91 \times 250 = 22.5$ m

$\therefore$ Net head on the turbine, $H = H_g - h_f = 250 - 22.50 = 227.5$ m

Velocity of jet, $V_1 = C_v\sqrt{2gH} = 0.975\sqrt{2 \times 9.81 \times 227.5} = 65.14$ m/s.

---

* Efficiency of runner means the ratio of power delivered to the runner to the power at the inlet of turbine *i.e.*, hydraulic efficiency.

(*i*) Power at the inlet of the turbine is given as,

$$\text{W.P.} = \text{Kinetic energy of the jet/s}$$

$$= \frac{\frac{1}{2}mV_1^2}{1000} = \frac{\frac{1}{2}(\rho \times Q)V_1^2}{1000} = \frac{1}{2} \times 1000 \times \frac{4.0 \times 65.14^2}{1000} = 8486.44 \text{ kW}$$

But $$\eta_h = \frac{\text{Power developed by turbine}}{\text{W.P.}}$$

$$\therefore \quad 0.90 = \frac{\text{Power developed by turbine}}{8486.44}$$

$\therefore$ Power developed by turbine $= 0.90 \times 8486.44 =$ **7637.8 kW. Ans.**

(*ii*) Discharge per jet, $$q = \frac{\text{Total discharge}}{\text{No. of jets}} = \frac{4.0}{4.0} = 1.0 \text{ m}^3/\text{s}$$

But $q =$ Area of one jet $\times$ Velocity of jet

$$= \frac{\pi}{4}d^2 \times V_1, \qquad \text{where } d = \text{Diameter of each jet}$$

$$\therefore \quad 1.0 = \frac{\pi}{4}d^2 \times 65.14$$

$$\therefore \quad d = \sqrt{\frac{4 \times 1.0}{\pi \times 65.14}} = \textbf{0.14 m. Ans.}$$

(*iii*) Let $D =$ Diameter of pipe line

Then $$h_f = \frac{4 \times f \times L \times V^{*2}}{D \times 2g}, \qquad \text{where } V^* = \text{Velocity through pipe}$$

$$\therefore \quad V^* = \frac{Q}{\text{Area}} = \frac{Q}{\frac{\pi}{4}D^2} = \frac{4Q}{\pi D^2}$$

And $$h_f = \frac{.0045 \times 3000 \times \left(\frac{4Q}{\pi D^2}\right)^2}{D \times 2g}$$

or $$22.50 = \frac{.0045 \times 3000 \times 16 \times Q^2}{D \times 2 \times 9.81 \times \pi^2 \times D^4} = \frac{.0045 \times 3000 \times 16 \times (4)^2}{D^5 \times 2 \times 9.81 \times \pi^2} = \frac{17.84}{D^5}$$

$$\therefore \quad D^5 = \frac{17.84}{22.50} = 0.7933$$

$\therefore$ $D = (.7933)^{1/5} =$ **0.955 m. Ans.**

Problem 18.10 *The following data is related to a Pelton wheel :*

Head at the base of the nozzle = *80 m*

Diameter of the jet = *100 mm*

Discharge of the nozzle = *0.30 m^3/s*
Power at the shaft = *206 kW*
Power absorbed in mechanical resistance = *4.5 kW*
Determine (i) Power lost in nozzle and (ii) Power lost due to hydraulic resistance in the runner.

Solution. Given :

Head at the base of the nozzle, H_1 = 80 m

Diameter of the jet, d = 100 mm = 0.1 m

$\therefore$ Area of the jet, $a = \frac{\pi}{4} = (0.1)^2 = .007854$

Discharge of the nozzle, Q = 0.30 m^3/s

Shaft power, S.P. = 206 kW

Power absorbed in mechanical resistance = 4.5 kW

Now discharge Q = area of jet × velocity of jet = $a \times V_1$

$$0.30 = .007854 \times V_1$$

$$\therefore \quad V_1 = \frac{0.30}{.007854} = 38.197 \text{ m/s}$$

Power at the base of the nozzle in kW

$$= \frac{\rho \times g \times Q \times H_1}{1000} = \frac{1000 \times 9.81 \times 0.30 \times 80}{1000} = 235.44$$

Power corresponding to kinetic energy of the jet in kW

$$= \frac{1}{2}\frac{(m)\, V_1^2}{1000} = \frac{1}{2}\frac{(\rho \times aV_1)\, V_1^2}{1000} = \frac{1}{2}\frac{\rho \times Q \times V_1^2}{1000}$$

$$= \frac{1}{2} \times 1000 \times \frac{0.3 \times 38.197^2}{1000} = 218.85 \text{ kW}.$$

(*i*) Power at the base of the nozzle

= Power of the jet + Power lost in nozzle

or 235.44 = 218.85 + Power lost in nozzle

$\therefore$ Power lost in nozzle = 235.44 – 218.85 = **16.59 kW. Ans.**

(*ii*) Also power at the base of nozzle = power at the shaft + power lost in nozzle + power lost in runner + power lost due to mechanical resistance

$\therefore$ 235.44 = 206 + 16.59 + Power lost in runner + 4.5

$\therefore$ Power lost in runner = 235.44 – (206 + 16.59 + 4.5) = 235.44 – 227.09 = **8.35 kW. Ans.**

18.6.3 Design of Pelton Wheel. Design of Pelton wheel means the following data is to be determined :

1. Diameter of the jet (d),
2. Diameter of wheel (D),
3. Width of the buckets which is = 5 × d,
4. Depth of the buckets which is = 1.2 × d, and
5. Number of buckets on the wheel.

Size of buckets means the width and depth of the buckets.

Problem 18.11 *A Pelton wheel is to be designed for a head of 60 m when running at 200 r.p.m. The Pelton wheel develops 95.6475 kW shaft power. The velocity of the buckets = 0.45 times the velocity of the jet, overall efficiency = 0.85 and co-efficient of the velocity is equal to 0.98.*

Solution. Given :

Head, $H = 60$ m

Speed $N = 200$ r.p.m

Shaft power, S.P. = 95.6475 kW

Velocity of bucket, $u = 0.45 \times$ Velocity of jet

Overall efficiency, $\eta_o = 0.85$

Co-efficient of velocity, $C_v = 0.98$

Design of Pelton wheel means to find diameter of jet (d), diameter of wheel (D), Width and depth of buckets and number of buckets on the wheel.

(*i*) *Velocity of jet*, $V_1 = C_v \times \sqrt{2gH} = 0.98 \times \sqrt{2 \times 9.81 \times 60} = 33.62$ m/s

$\therefore$ Bucket velocity, $u = u_1 = u_2 = 0.45 \times V_1 = 0.45 \times 33.62 = 15.13$ m/s

But $u = \dfrac{\pi DN}{60}$, where D = Diameter of wheel

$\therefore$ $15.13 = \dfrac{\pi \times D \times 200}{60}$ or $D = \dfrac{60 \times 15.13}{\pi \times 200}$ = **1.44 m. Ans.**

(*ii*) *Diameter of the jet* (d)

Overall efficiency $\eta_o = 0.85$

But $\eta_o = \dfrac{\text{S.P.}}{\text{W.P.}} = \dfrac{95.6475}{\left(\dfrac{\text{W.P.}}{1000}\right)} = \dfrac{95.6475 \times 1000}{\rho \times g \times Q \times H}$ ($\because$ W.P. = ρgQH)

$$= \frac{95.6475 \times 1000}{1000 \times 9.81 \times Q \times 60}$$

$\therefore$ $Q = \dfrac{95.6475 \times 1000}{\eta_o \times 1000 \times 9.81 \times 60} = \dfrac{95.6475 \times 1000}{0.85 \times 1000 \times 9.81 \times 60} = 0.1912$ m^3/s.

But the discharge, Q = Area of jet $\times$ Velocity of jet

$\therefore$ $0.1912 = \dfrac{\pi}{4} d^2 \times V_1 = \dfrac{\pi}{4} d^2 \times 33.62$

$\therefore$ $d = \sqrt{\dfrac{4 \times 0.1912}{\pi \times 33.62}} = 0.085$ m = **85 mm. Ans.**

(*iii*) *Size of buckets*

Width of buckets $= 5 \times d = 5 \times 85 = 425$ mm

Depth of buckets $= 1.2 \times d = 1.2 \times 85 =$ **102 mm. Ans.**

(*iv*) *Number of buckets on the wheel* is given by equation (18.17) as

$$Z = 15 + \frac{D}{2d} = 15 + \frac{1.44}{2 \times .085} = 15 + 8.5 = \textbf{23.5 say 24. Ans.}$$

Problem 18.12 *Determine the power given by the jet of water to the runner of a Pelton wheel which is having tangential velocity as 20 m/s. The net head on the turbine is 50 m and discharge through the jet water is 0.03 m^3/s. The side clearance angle is 15° and take C_v = 0.975.*

Solution. Given :

Tangential velocity of wheel, $u = u_1 = u_2 = 20$ m/s

Net head, $H = 50$ m

Discharge , $Q = 0.03$ m^3/s

Side clearance angle, $\phi = 15°$

Co-efficient of velocity, $C_v = 0.975$

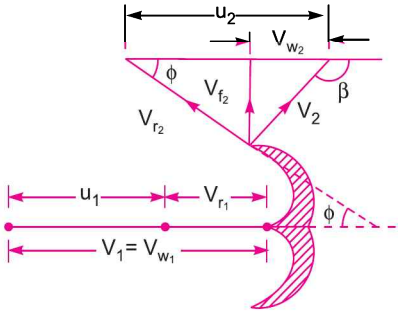

Fig. 18.9

Velocity of the jet, $V_1 = C_v \times \sqrt{2gH}$

$= 0.975 \times \sqrt{2 \times 9.81 \times 50}$

$= 30.54$ m/s

From inlet triangle, $V_{w_1} = V_1 = 30.54$ m/s

$V_{r_1} = V_{w_1} - u_1 = 30.54 - 20.0 = 10.54$ m/s

From outlet velocity triangle, we have

$V_{r_2} = V_{r_1} = 10.54$ m/s

$V_{r_2} \cos \phi = 10.54 \cos 15° = 10.18$ m/s

As $V_{r_2} \cos \phi$ is less than u_2, the velocity triangle at outlet will be as shown in Fig. 18.9.

$\therefore$ $V_{w_2} = u_2 - V_{r_2} \cos \phi = 20 - 10.18 = 9.82$ m/s.

Also as β is an obtuse angle, the work done per second on the runner,

$= \rho a V_1 \left[V_{w_1} - V_{w_2}\right] \times u = \rho Q \left[V_{w_1} - V_{w_2}\right] \times u$

$= 1000 \times .03 \times [30.54 - 9.82] \times 20 = 12432$ Nm/s

$\therefore$ Power given to the runner in kW $= \dfrac{\text{Work done per second}}{1000} = \dfrac{12432}{1000} =$ **12.432 kW. Ans.**

Problem 18.13 *The three-jet Pelton turbine is required to generate 10,000 kW under a net head of 400 m. The blade angle at outlet is 15° and the reduction in the relative velocity while passing over the blade is 5%. If the overall efficiency of the wheel is 80%, C_v = 0.98 and speed ratio = 0.46, then find: (i) the diameter of the jet, (ii) total flow in m^3/s and (iii) the force exerted by a jet on the buckets.*

If the jet ratio is not to be less than 10, find the speed of the wheel for a frequency of 50 hertz/sec and the corresponding wheel diameter.

Solution. Given :

No. of jets $= 3$

Total power, $P = 10000$ kW

Net head, $H = 400$ m

Blade angle at outlet, $\phi = 15°$

Relative velocity at outlet $= 0.95$ of relative velocity at inlet

or $V_{r_2} = 0.95\ V_{r_1}$

Overall efficiency, $\eta_o = 0.80$

Value of $C_v = 0.98$

Speed ratio $= 0.46$

Frequency, $f = 50$ hertz/sec

Now using equation (18.6 *A*), $\eta_o = \dfrac{P}{\left(\dfrac{\rho \times g \times Q \times H}{1000}\right)}$

where Q = Total discharge through three nozzles and $\rho = 1000$ kg/m^3

$$\therefore \quad 0.80 = \frac{10000}{\left(\dfrac{1000 \times 9.81 \times Q \times 400}{1000}\right)}$$

$$\therefore \quad Q = \frac{10000}{0.8 \times 9.81 \times 400} = \textbf{3.18 m}^3\textbf{/s. Ans.}$$

Discharge through one nozzle $= \dfrac{3.18}{3} = 1.06$ m^3/s.

(*i*) **Diameter of the jet (d).**

Discharge through one nozzle = Area of one jet × Velocity

But velocity of jet, $V_1 = C_v \times \sqrt{2gH} = 0.98 \times \sqrt{2 \times 9.81 \times 400} = 87$ m/s

$$\therefore \quad 1.06 = \frac{\pi}{4} d^2 \times 87$$

$$\therefore \quad d = \sqrt{\frac{4 \times 1.06}{\pi \times 87}} = 0.125 \text{ m} = \textbf{125 mm. Ans.}$$

(*ii*) **Total flow in m^3/s** $= 3.18$ m^3/s.

(*iii*) **Force exerted by a jet on the wheel.**

$$\text{Speed ratio} = \frac{u_1}{\sqrt{2gH}}$$

$$\therefore \quad u_1 = \text{Speed ratio} \times \sqrt{2gH} = 0.46 \times \sqrt{2 \times 9.81 \times 400} = 40.75 \text{ m/s}$$

Now $V_{r_1} = V_1 - u_1 = 87 - 40.75 = 46.25$ m/s

and $V_{r_2} = 0.95\ V_{r_1} = 0.95 \times 46.25 = 44.0$ m/s

$V_{w_1} = V_1 = 87$ m/s

$V_{w_2} = V_{r_2} \cos \phi - u_2 = 44 \times \cos 15° - 40.75$ ($\because \quad u_1 = u_2 = 40.75$ m/s)

$= 1.75$ m/s

Force exerted by a single jet on the buckets

$= \rho \times$ discharge through one jet $\times (V_{w_1} + V_{w_2})$

$= 1000 \times 1.06\ (87 + 1.75) = 94075$ N = **94.075 kN. Ans.**

(*iv*) **Jet ratio** $= 10 \text{ or } \frac{D}{d} = 10$

$\therefore$ Dia. of wheel, $D = 10 \times d = 10 \times 0.125 = 1.25$ m

But, $u_1 = \frac{\pi DN}{60}$

$\therefore$ $N = \frac{60 \times u_1}{\pi \times D} = \frac{60 \times 40.75}{\pi \times 1.25} = 620$ r.p.m.

Now using the relation, $N = \frac{60 \times f}{p}$

where f = frequency in hertz per second,

p = pairs of poles, and N = speed.

$\therefore$ $p = \frac{60 \times f}{N} = \frac{60 \times 50}{620} = 4.85$

Take the next whole number *i.e.*, 5. Hence, pairs of poles are 5.

Now corresponding to five pairs of poles, the speed of the turbine will become as given below :

$$N = \frac{60 \times f}{p} = \frac{60 \times 50}{5} = 600 \text{ r.p.m.}$$

But $u = \frac{\pi DN}{60}$

As the peripheral velocity is constant. Hence with the change of speed, diameter of wheel will change.

$\therefore$ $D = \frac{60 \times u}{\pi \times N} = \frac{60 \times 40.75}{\pi \times 600} = 1.3$ m

$\therefore$ Jet ratio becomes $= \frac{D}{d} = \frac{1.30}{0.125} > 10$

Hence the given condition is satisfied.

▶ 18.7 RADIAL FLOW REACTION TURBINES

Radial flow turbines are those tubines in which the water flows in the radial direction. The water may flow radially from outwards to inwards (*i.e.*, towards the axis of rotation) or from inwards to outwards. If the water flows from outwards to inwards through the runner, the turbine is known as inward radial flow turbine. And if the water flows from inwards to outwards, the turbine is known as outward radial flow turbine.

Reaction turbine means that the water at the inlet of the turbine possesses kinetic energy as well as pressure energy. As the water flows through the runner, a part of pressure energy goes on changing into kinetic energy. Thus the water through the runner is under pressure. The runner is completely enclosed in an air-tight casing and casing and the runner is always full of water.

18.7.1 Main Parts of a Radial Flow Reaction Turbine. The main parts of a radial flow reaction turbine are :

1. Casing,
2. Guide mechanism,
3. Runner, and
4. Draft-tube.

1. Casing. As mentioned above that in case of reaction turbine, casing and runner are always full of water. The water from the penstocks enters the casing which is of spiral shape in which area of cross-section of the casing goes on decreasing gradually. The casing completely surrounds the runner of the turbine. The casing as shown in Fig. 18.10 is made of spiral shape, so that the water may enter the runner at constant velocity throughout the circumference of the runner. The casing is made of concrete, cast steel or plate steel.

2. Guide Mechanism. It consists of a stationary circular wheel all round the runner of the turbine. The stationary guide vanes are fixed on the guide mechanism. The guide vanes allow the water to strike the vanes fixed on the runner without shock at inlet. Also by a suitable arrangement, the width between two adjacent vanes of guide mechanism can be altered so that the amount of water striking the runner can be varied.

3. Runner. It is a circular wheel on which a series of radial curved vanes are fixed. The surface of the vanes are made very smooth. The radial curved vanes are so shaped that the water enters and leaves the runner without shock. The runners are made of cast steel, cast iron or stainless steel. They are keyed to the shaft.

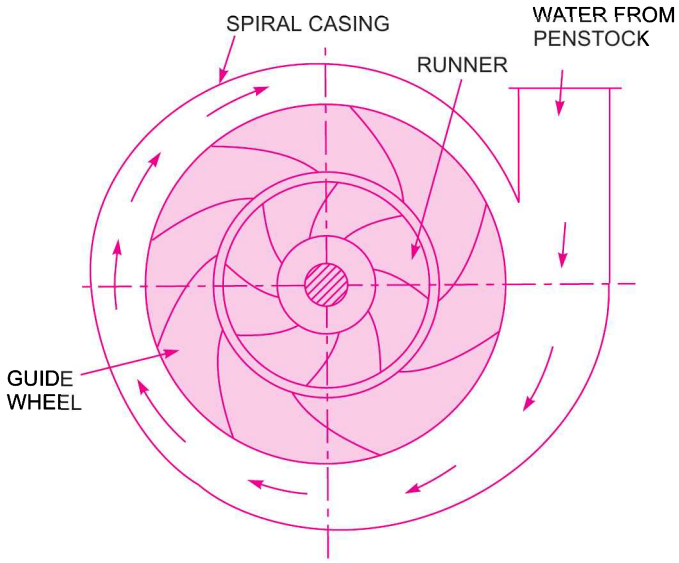

Fig. 18.10 *Main parts of a radial reaction turbines.*

4. Draft-tube. The pressure at the exit of the runner of a reaction turbine is generally less than atmospheric pressure. The water at exit cannot be directly discharged to the tail race. A tube or pipe of gradually increasing area is used for discharging water from the exit of the turbine to the tail race. This tube of increasing area is called draft tube.

18.7.2 Inward Radial Flow Turbine. Fig. 18.11 shows inward radial flow turbine, in which case the water from the casing enters the stationary guiding wheel. The guiding wheel consists of guide vanes which direct the water to enter the runner which consists of moving vanes. The water flows over the moving vanes in the inward radial direction and is discharged at the inner diameter of the runner. The outer diameter of the runner is the inlet and the inner diameter is the outlet.

Velocity Triangles and Work done by Water on Runner. In Chapter 17 (Art. 17.4.6), we have discussed in detail the force exerted by the water on the radial curved vanes fixed on a wheel. From the force exerted on the vanes,the work done by water, the horse power given by the water to the vanes and

efficiency of the vanes can be obtained. Also we have drawn velocity triangles at inlet and outlet of the moving radial vanes in Fig. 17.23. From the velocity triangles, the work done by the water on the runners, horse power and efficiency of the turbine can be obtained.

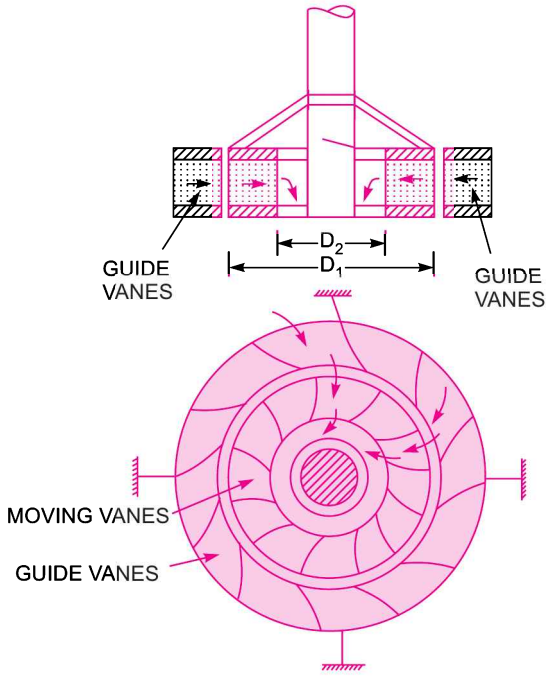

Fig. 18.11 *Inward radial flow turbine.*

The work done per second on the runner by water is given by equation (17.26) as

$$= \rho a V_1 [V_{w_1} u_1 \pm V_{w_2} u_2]$$

$$= \rho Q [V_{w_1} u_1 \pm V_{w_2} u_2] \qquad (\because \quad aV_1 = Q) \quad ...(18.18)$$

The equation (18.18) also represents the energy transfer per second to the runner.

where V_{w_1} = Velocity of whirl at inlet,

V_{w_2} = Velocity of whirl at outlet,

u_1 = Tangential velocity of wheel at inlet

$= \dfrac{\pi D_1 \times N}{60}$, where D_1 = Outer dia. of runner,

u_2 = Tangential velocity of wheel at outlet

$= \dfrac{\pi D_2 \times N}{60}$, where D_2 = Inner dia. of runner, N = Speed of the turbine in .r.p.m.

The work done per second per unit weight of water per second.

$$= \frac{\text{Work done per second}}{\text{Weight of water striking per second}}$$

$$= \frac{\rho Q \left[V_{w_1} u_1 \pm V_{w_2} u_2\right]}{\rho Q \times g} = \frac{1}{g}\left[V_{w_1} u_1 \pm V_{w_2} u_2\right] \qquad ...(18.19)$$

The equation (18.19) represents the energy transfer per unit weight/s to the runner. This equation is known by **Euler's equation** of hydrodynamics machines. This is also known as fundamental equation of hydrodynamic machines. This equation was given by Swiss scientist *L.* Euler.

In equation (18.19), +ve sign is taken if angle β is an acute angle. If β is an obtuse angle then –ve sign is taken. If β = 90°, then $V_{w_2} = 0$ and work done per second per unit weight of water striking/s become as

$$= \frac{1}{g} V_{w_1} u_1 \qquad ...(18.20)$$

Hydraulic efficiency is obtained from equation (18.2) as

$$\eta_h = \frac{\text{R.P.}}{\text{W.P.}} = \frac{\frac{W}{1000g}[V_{w_1} u_1 \pm V_{w_2} u_2]}{\frac{W \times H}{1000}} = \frac{(V_{w_1} u_1 \pm V_{w_2} u_2)}{gH} \qquad ...(18.20A)$$

where R.P. = Runner power *i.e.*, power delivered by water to the runner
W.P. = Water power

If the discharge is radial at outlet, then $V_{w_2} = 0$

$$\eta_h = \frac{V_{w_1} u_1}{gH} \qquad ...(18.20B)$$

18.7.3 Degree of Reaction. Degree of reaction is defined as the ratio of pressure energy change inside a runner to the total energy change inside the runner. It is represented by 'R'. Hence mathematically it can be written as

$$R = \frac{\text{Change of pressure energy inside the runner}}{\text{Change of total energy inside the runner}} \qquad ...(18.20C)$$

The equation (18.19) which is the fundamental equation of hydrodynamic machines, represents the energy transfer per unit weight to the runner. This is also known as the total energy change inside the runner per unit weight.

∴ Change of total energy per unit weight inside the runner

$$= \frac{1}{g}[V_{w_1} u_1 \pm V_{w_2} u_2]$$

Let H_e = Change of total energy per unit weight inside the runner.

Then $$H_e = \frac{1}{g}[V_{w_1} u_1 \pm V_{w_2} u_2] \qquad ...(18.20D)$$

Let us find the values of $V_{w_1} u_1$ and $V_{w_2} u_2$ from inlet and outlet velocity triangles.

Now from inlet velocity triangle, we know that [Refer to Fig. 18.11(*a*)]

$$V_{w_1} = u_1 + V_{r_1 x}, \quad \text{where } V_{r_1 x} = V_{r_1} \cos\theta = \sqrt{V_{r_1}^2 - V_{f_1}^2}$$

$$= u_1 + \sqrt{V_{r_1}^2 - V_{f_1}^2}$$

$$= u_1 + \sqrt{V_{r_1}^2 - (V_1^2 - V_{w_1}^2)} \quad [\because \text{From triangle } ABC,\ V_{f_1}^2 = V_1^2 - V_{w_1}^2]$$

$$\therefore \qquad (V_{w_1} - u_1) = \sqrt{V_{r_1}^2 - (V_1^2 - V_{w_1}^2)}$$

Squaring both sides, we get

$$(V_{w_1} - u_1)^2 = V_{r_1}^2 - (V_1^2 - V_{w_1}^2)$$

or $$V_{w_1}^2 + u_1^2 - 2V_{w_1}u_1 = V_{r_1}^2 - V_1^2 + V_{w_1}^2$$

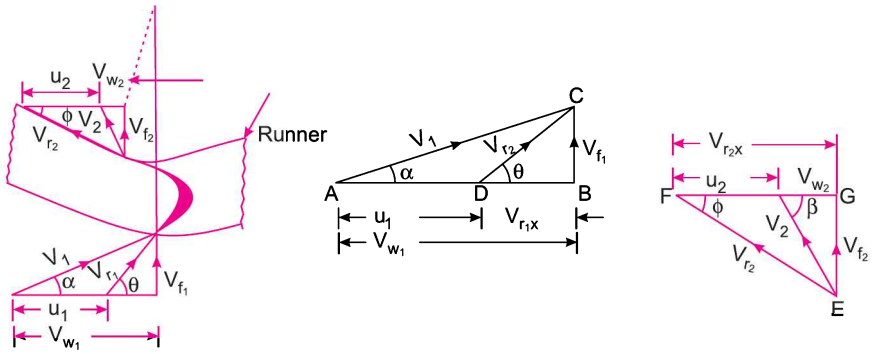

Fig. 18.11 (*a*)

or $$V_{w_1}^2 + u_1^2 - V_{r_1}^2 + V_1^2 - V_{w_1}^2 = 2V_{w_1}u_1$$

or $$u_1^2 - V_{r_1}^2 + V_1^2 = 2V_{w_1}u_1$$

or $$2V_{w_1}u_1 = u_1^2 - V_{r_1}^2 + V_1^2$$

or $$V_{w_1}u_1 = \frac{1}{2}[u_1^2 - V_{r_1}^2 + V_1^2] \quad ...(i)$$

Similarly from outlet triangle, we know that [Refer to Fig. 18.11(*a*)]

$$V_{w_2} = V_{r_2x} - u_2$$

$$= \sqrt{V_{r_2}^2 - V_{f_2}^2} - u_2, \text{ where } V_{r_2x} = V_{r_2}\cos\theta = \sqrt{V_{r_2}^2 - V_{f_2}^2}$$

$$= \sqrt{V_{r_2}^2 - (V_2^2 - V_{w_2}^2)} - u_2 \quad \therefore \quad V_{f_2}^2 = V_2^2 - V_{w_2}^2$$

$\therefore$ $$V_{w_2} + u_2 = \sqrt{V_{r_2}^2 - V_2^2 + V_{w_2}^2}$$

Squaring both sides, we get

$$(V_{w_2} + u_2)^2 = V_{r_2}^2 - V_2^2 + V_{w_2}^2$$

or $$V_{w_2}^2 + u_2^2 + 2V_{w_2}u_2 = V_{r_2}^2 - V_2^2 + V_{w_2}^2$$

or $$2V_{w_2}u_2 = V_{r_2}^2 - V_2^2 + V_{w_2}^2 - V_{w_2}^2 - u_2^2$$

or $$2V_{w_2}u_2 = V_{r_2}^2 - V_2^2 - u_2^2$$

or $$V_{w_2}u_2 = \frac{1}{2}[V_{r_2}^2 - V_2^2 - u_2^2] \quad ...(ii)$$

In the above case of velocity triangles under consideration, the change of total energy per unit weight inside the runner is equal to $\frac{1}{g}[V_{w_1}u_1 + V_{w_2}u_2]$

Substituting the values of $V_{w_1}u_1$ and $V_{w_2}u_2$ from equations (*i*) and (*ii*) into equation (18.20 *D*), we get Change of total energy per unit weight inside the runner as

$$H_e = \frac{1}{g}\left[\frac{1}{2}\left(u_1^2 - V_{r_1}^2 + V_1^2\right) + \frac{1}{2}\left(V_{r_2}^2 - V_2^2 - u_2^2\right)\right]$$

$$= \frac{1}{2g}\left[\left(u_1^2 - u_2^2\right) + \left(V_1^2 - V_2^2\right) + \left(V_{r_2}^2 - V_{r_1}^2\right)\right]$$

$$= \frac{V_1^2 - V_2^2}{2g} + \frac{u_1^2 - u_2^2}{2g} + \frac{V_{r_2}^2 - V_{r_1}^2}{2g} \qquad ...(18.20E)$$

The above equation consists of three terms. The first term represents the change in kinetic energy of the fluid per unit weight and the second term represents the change of energy per unit weight due to centrifugal action. The third term represents the change in static pressure energy per unit weight, as per Bernoulli's equation applied to relative flow through runner passage by reducing the rotating system into stationary system. We know that the energy change due to centrifugal action takes place in the form of pressure energy. [When a container containing a liquid is rotated, then due to centrifugal action there is change of pressure energy *i.e.*, $h = \frac{\Delta p}{\rho g} = \frac{u_2^2 - u_1^2}{2g}\Big]$. Hence, the last two terms in equation (18.20*E*) represents the change in pressure energy inside the runner passage per unit weight.

$\therefore$ Change in pressure energy inside the runner per unit weight $= \frac{u_1^2 - u_2^2}{2g} + \frac{V_{r_2}^2 - V_{r_1}^2}{2g}$ ...(*iii*)

Now the equation (18.20*C*) becomes as

$$R = \frac{\text{Change of pressure energy inside the runner per unit weight}}{\text{Change of total energy inside the runner per unit weight}}$$

$$= \left(\frac{\left(u_1^2 - u_2^2\right)}{2g} + \frac{V_{r_2}^2 - V_{r_1}^2}{2g}\right) \Bigg/ \left[\left(\frac{V_1^2 - V_2^2}{2g}\right) + \left(\frac{u_1^2 - u_2^2}{2g}\right) + \left(\frac{V_{r_2}^2 - V_{r_1}^2}{2g}\right)\right]$$

or $$R = \frac{\left(u_1^2 - u_2^2\right) + \left(V_{r_2}^2 - V_{r_1}^2\right)}{\left(V_1^2 - V_2^2\right) + \left(u_1^2 - u_2^2\right) + \left(V_{r_2}^2 - V_{r_1}^2\right)} \qquad ...(18.20F)$$

or $$R = \frac{\left(V_1^2 - V_2^2\right) + \left(u_1^2 - u_2^2\right) + \left(V_{r_2}^2 - V_{r_1}^2\right) - \left(V_1^2 - V_2^2\right)}{\left(V_1^2 - V_2^2\right) + \left(u_1^2 - u_2^2\right) + \left(V_{r_2}^2 - V_{r_1}^2\right)}$$

$$= 1 - \frac{\left(V_1^2 - V_2^2\right)}{\left(V_1^2 - V_2^2\right) + \left(u_1^2 - u_2^2\right) + \left(V_{r_2}^2 - V_{r_1}^2\right)} \qquad ...(18.20G)$$

From equation (18.20*E*) , we know that

$$H_e = \frac{V_1^2 - V_2^2}{2g} + \frac{u_1^2 - u_2^2}{2g} + \frac{V_{r_2}^2 - V_{r_1}^2}{2g}$$

or $$2gH_e = (V_1^2 - V_2^2) + (u_1^2 - u_2^2) + (V_{r_2}^2 - V_{r_1}^2)$$

Now the equation (18.20*G*) can be written as

$$R = 1 - \frac{\left(V_1^2 - V_2^2\right)}{2g\ H_e} \qquad ...(18.20H)$$

Values of *R* for Pelton turbine and other actual reaction turbines

(*i*) *For a Pelton turbine,*

$$u_1 = u_2 \text{ and } V_{r_2} = V_{r_1}$$

∴ From equation (18.20*G*)

$$R = 1 - \frac{\left(V_1^2 - V_2^2\right)}{\left(V_1^2 - V_2^2\right)} = 1 - 1 = 0$$

(*ii*) *For an actual reaction turbine,* generally, the angle β is 90° so that the loss of kinetic energy at outlet is minimum (*i.e.*, V_2 is minimum).

Hence in outlet velocity triangle, V_{w_2} becomes zero

(*i.e.*, $V_{w_2} = 0$). Also $V_2 = V_{f_2}$ [Refer to Fig. 18.11(*b*)]

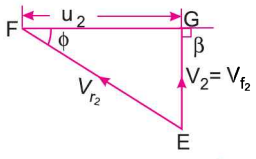

Fig. 18.11 (*b*)

Also there is not much change in velocity of flow. This means $V_{f_1} = V_{f_2}$

From equation (18.20*D*), we know that

$$H_e = \frac{1}{g}[V_{w_1}u_1 + V_{w_2}u_2]$$

$$= \frac{1}{g}V_{w_1}u_1 \qquad \left(\because\ V_{w_2} = 0\right)$$

$$= \frac{1}{g}[V_{f_1}\cot\alpha]\,[V_{f_1}\cot\alpha - V_{f_1}\cot\theta] \qquad \text{[Refer to Fig. 18.11(}a\text{)]}$$

$$[\because\ V_{w_1} = V_{f_1}\cot\alpha \text{ and } u_1 = V_{w_1} - V_{f_1}\cot\theta = V_{f_1}\cot\alpha - V_{f_1}\cot\theta]$$

$$= \frac{1}{g}V_{f_1}^2\cot\alpha\,[\cot\alpha - \cot\theta\,]$$

Now $$V_1^2 - V_2^2 = (V_{f_1}\ \text{cosec}\ \alpha)^2 - V_{f_2}^2 \qquad (\because\ V_2 = V_{f_2})$$

$$= V_{f_1}^2\ \text{cosec}^2\alpha - V_{f_1}^2 \qquad (\because\ V_{f_2} = V_{f_1})$$

or $$V_1^2 - V_2^2 = V_{f_1}^2\ (\text{cosec}^2\alpha - 1)$$

$$= V_{f_1}^2\cot^2\alpha \qquad (\because\ \text{cosec}^2\alpha - 1 = \cot^2\alpha)$$

Substituting the value of H_e and $(V_1^2 - V_2^2)$ in equation (18.20*H*), we get

$$R = 1 - \frac{V_{f_1}^2\cot^2\alpha}{2g \times [\frac{1}{g}V_{f_1}^2\cot\alpha(\cot\alpha - \cot\theta)]}$$

$$= 1 - \frac{\cot\alpha}{2(\cot\alpha - \cot\theta)} \qquad ...(18.20I)$$

18.7.4 Definitions. The following terms are generally used in case of reaction radial flow turbines which are defined as :

(*i*) **Speed Ratio.** The speed ratio is defind as = $\frac{u_1}{\sqrt{2gH}}$

where u_1 = Tangential velocity of wheel at inlet.

(*ii*) **Flow Ratio.** The ratio of the velocity of flow at inlet (V_{f_1}) to the velocity given $\sqrt{2gH}$ is known as flow ratio or it is given as

$$= \frac{V_{f_1}}{\sqrt{2gH}}, \text{ where } H = \text{Head on turbine}$$

(*iii*) **Discharge of the Turbine.** The discharge through a reaction radial flow turbine is given by

$$Q = \pi D_1 B_1 \times V_{f_1} = \pi D_2 \times B_2 \times V_{f_2} \qquad ...(18.21)$$

where D_1 = Diameter of runner at inlet,

B_1 = Width of runner at inlet,

V_{f_1} = Velocity of flow at inlet, and

D_2, B_2, V_{f_2} = Corresponding values at outlet.

If the thickness of vanes are taken into consideration, then the area through which flow takes place is given by $(\pi D_1 - n \times t)$

where n = Number of vanes on runner and t = Thickness of each vane

The discharge Q, then is given by $Q = (\pi D_1 - n \times t)\, B_1 \times V_{f_1}$ ...(18.22)

(*iv*) The head (H) on the turbine is given by $H = \frac{p_1}{\rho \times g} + \frac{V_1^2}{2g}$ ...(18.23)

where p_1 = Pressure at inlet.

(*v*) **Radial Discharge.** This means the angle made by absolute velocity with the tangent on the wheel is 90° and the component of the whirl velocity is zero. Radial discharge at outlet means $\beta = 90°$ and $V_{w_2} = 0$, while radial discharge at outlet means $\alpha = 90°$ and $V_{w_1} = 0$.

(*vi*) If there is no loss of energy when water flows through the vanes then we have

$$H - \frac{V_2^2}{2g} = \frac{1}{g}[V_{w_1} u_1 \pm V_{w_2} u_2]. \qquad ...(18.24)$$

Problem 18.14 *An inward flow reaction turbine has external and internal diameters as 1 m and 0.5 m respectively. The velocity of flow through the runner is constant and is equal to 1.5 m/s. Determine :*

(i) Discharge through the runner, and

(ii) Width of the turbine at outlet if the width of the turbine at inlet = 200 mm.

Solution. Given :

External diameter of turbine, $D_1 = 1$ m

Internal diameter of turbine, $D_2 = 0.5$ m

Velocity of flow at inlet and outlet, $V_{f_1} = V_{f_2} = 1.5$ m/s

Width of turbine at inlet, $B_1 = 200$ mm $= 0.20$ m

Let the width at outlet $= B_2$

Using equation (18.21) for discharge,

$$Q = \pi D_1 B_1 \times V_{f_1} = \pi \times 1 \times 0.20 \times 1.5 = \mathbf{0.9425\ m^3/s.\ Ans.}$$

Also $\pi D_1 B_1 V_{f_1} = \pi D_2 B_2 V_{f_2}$ or $D_1 B_1 = D_2 B_2$ $\left(\because \quad \pi V_{f_1} = \pi V_{f_2}\right)$

$$\therefore \quad B_2 = \frac{D_1 \times B_1}{D_2} = \frac{1 \times 0.20}{0.5} = 0.40 \text{ m} = \mathbf{400\ mm.\ Ans.}$$

Problem 18.15 *An inward flow reaction turbine has external and internal diameters as 0.9 m and 0.45 m respectively. The turbine is running at 200 r.p.m. and width of turbine at inlet is 200 mm. The velocity of flow through the runner is constant and is equal to 1.8 m/s. The guide blades make an angle of 10° to the tangent of the wheel and the discharge at the outlet of the turbine is radial. Draw the inlet and outlet velocity triangles and determine:*

(i) The absolute velocity of water at inlet of runner,
(ii) The velocity of whirl at inlet, (iii) The relative velocity at inlet,
(iv) The runner blade angles, (v) Width of the runner at outlet,
(vi) Mass of water flowing through the runner per second,
(vii) Head at the inlet of the turbine,
(viii) Power developed and hydraulic efficiency of the turbine.

Solution. Given :

External Dia., $D_1 = 0.9$ m
Internal Dia., $D_2 = 0.45$ m
Speed, $N = 200$ r.p.m.
Width at inlet, $B_1 = 200$ mm $= 0.2$ m
Velocity of flow, $V_{f_1} = V_{f_2} = 1.8$ m/s
Guide blade angle, $\alpha = 10°$
Discharge at outlet = Radial
$\therefore$ $\beta = 90°$ and $V_{w_2} = 0$

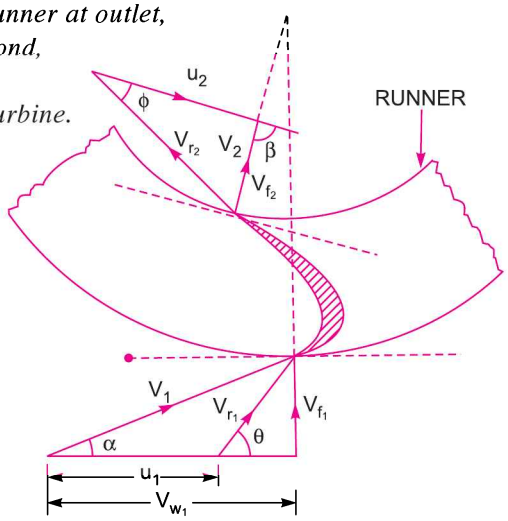

Fig 18.12

Tangential velocity of wheel at inlet and outlet are :

$$u_1 = \frac{\pi D_1 N}{60} = \frac{\pi \times .9 \times 200}{60} = 9.424 \text{ m/s}$$

$$u_2 = \frac{\pi D_2 N}{60} = \frac{\pi \times .45 \times 200}{60} = 4.712 \text{ m/s.}$$

(*i*) *Absolute velocity of water at inlet of the runner i.e.*, V_1

From inlet velocity triangle,

$$V_1 \sin \alpha = V_{f_1}$$

$$\therefore \quad V_1 = \frac{V_{f_1}}{\sin \alpha} = \frac{18}{\sin 10^\circ} = \textbf{10.365 m/s. Ans.}$$

(*ii*) *Velocity of whirl at inlet, i.e.*, V_{w_1}

$$V_{w_1} = V_1 \cos \alpha = 10.365 \times \cos 10° = \textbf{10.207 m/s. Ans.}$$

(*iii*) *Relative velocity at inlet, i.e.*, V_{r_1}

$$V_{r_1} = \sqrt{V_{r_1}^3 + (V_{w_1} - u_1)^2} = \sqrt{1.8^2 + (10.207 - 9.424)^2}$$

$$= \sqrt{3.24 + .613} = \textbf{1.963 m/s. Ans.}$$

(*iv*) *The runner blade angles* means the angle θ and ϕ

Now $$\tan \theta = \frac{V_{f_1}}{(V_{w_1} - u_1)} = \frac{1.8}{(10.207 - 9.424)} = 2.298$$

$\therefore$ $\theta = \tan^{-1} 2.298 = \textbf{66.48°}$ or $\textbf{66° 29'}$. **Ans.**

From outlet velocity triangle, we have

$$\tan \phi = \frac{V_{f_2}}{u_2} = \frac{1.8}{4.712} = \tan 20.9°$$

$\therefore$ $\phi = \mathbf{20.9°}$ or $\mathbf{20° 54.4'}$. **Ans.**

(*v*) *Width of runner at outlet, i.e.*, B_2

From equation (18.21), we have

$$\pi D_1 B_1 V_{f_1} = \pi D_2 B_2 V_{f_2} \text{ or } D_1 B_1 = D_2 B_2 \qquad (\because \ \pi V_{f_1} = \pi V_{f_2} \text{ as } V_{f_1} = V_{f_2})$$

$\therefore$ $$B_2 = \frac{D_1 B_1}{D_2} = \frac{0.90 \times 0.20}{0.45} = 0.40 \text{ m} = \mathbf{400 \text{ mm}}. \text{ Ans.}$$

(*vi*) *Mass of water flowing through the runner per second.*

The discharge, $Q = \pi D_1 B_1 V_{f_1} = \pi \times 0.9 \times 0.20 \times 1.8 = 1.0178 \text{ m}^3/\text{s}.$

$\therefore$ Mass $= \rho \times Q = 1000 \times 1.0178 \text{ kg/s} = \mathbf{1017.8 \text{ kg/s}}$. **Ans.**

(*vii*) *Head at the inlet of turbine, i.e., H.*

Using equation (18.24), we have

$$H - \frac{V_2^2}{2g} = \frac{1}{g}(V_{w_1} u_1 \pm V_{w_2} u_2) = \frac{1}{g}(V_{w_1} u_1) \qquad (\because \text{ Here } V_{w_2} = 0)$$

$$H = \frac{1}{g} V_{w_1} u_1 + \frac{V_2^2}{2g} = \frac{1}{9.81} \times 10.207 \times 9.424 + \frac{1.8^2}{2 \times 9.81} \quad (\because V_2 = V_{f_2})$$

$$= 9.805 + 0.165 = \mathbf{9.97 \text{ m}}. \text{ Ans.}$$

(*viii*) *Power developed, i.e.*, $P = \dfrac{\text{Work done per second on runner}}{1000}$

$$= \frac{\rho Q \left[V_{w_1} u_1\right]}{1000} \qquad \text{[Using equation (18.18)]}$$

$$= 1000 \times \frac{1.0178 \times 10.207 \times 9.424}{1000} = \mathbf{97.9 \text{ kW}}. \text{ Ans.}$$

Hydraulic efficiency is given by equation (18.20*B*) as

$$\eta_h = \frac{V_{w_1} u_1}{gH} = \frac{10.207 \times 9.424}{9.81 \times 9.97} = 0.9834 = \mathbf{98.34\%}. \text{ Ans.}$$

Problem 18.16 *A reaction turbine works at 450 r.p.m. under a head of 120 metres. Its diameter at inlet is 120 cm and the flow area is 0.4 m^2. The angles made by absolute and relative velocities at inlet are 20° and 60° respectively with the tangential velocity. Determine :*

(a) The volume flow rate, (b) The power developed, and

(c) Hydraulic efficiency.

Assume whirl at outlet to be zero.

Solution. Given :

Speed of turbine, $N = 450$ r.p.m.

Head, $H = 120$ m

Diameter at inlet, $D_1 = 120 \text{ cm} = 1.2 \text{ m}$

Flow area, $\pi D_1 \times B_1 = 0.4 \text{ m}^2$

Angle made by absolute velocity at inlet, $\alpha = 20°$

Angle made by the relative velocity at inlet, $\theta = 60°$

Whirl at outlet, $V_{w_2} = 0$

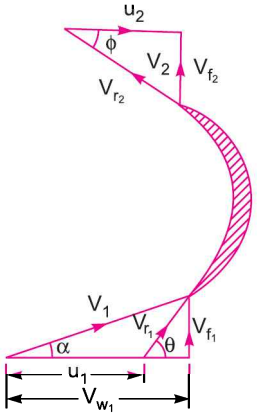

Fig. 18.13

Tangential velocity of the turbine at inlet,

$$u_1 = \frac{\pi D_1 N}{60} = \frac{\pi \times 1.2 \times 450}{60} = 28.27 \text{ m/s}$$

From inlet velocity triangle,

$$\tan \alpha = \frac{V_{f_1}}{V_{w_1}} \text{ or } \tan 20° = \frac{V_{f_1}}{V_{w_1}} \text{ or } \frac{V_{f_1}}{V_{w_1}} = \tan 20° = 0.364$$

$$\therefore \quad V_{f_1} = 0.364\ V_{w_1}$$

Also
$$\tan \theta = \frac{V_{f_1}}{V_{w_1} - u_1} = \frac{0.364\ V_{w_1}}{V_{w_1} - 28.27} \qquad (\because \quad V_{f_1} = 0.364\ V_{w_1})$$

or
$$\frac{0.364\ V_{w_1}}{V_{w_1} - 28.27} = \tan \theta = \tan 60° = 1.732$$

$$\therefore \quad 0.364 V_{w_1} = 1.732(V_{w_1} - 28.27) = 1.732 V_{w_1} - 48.96$$

or
$$(1.732 - 0.364)\ V_{w_1} = 48.96$$

$$\therefore \quad V_{w_1} = \frac{48.96}{(1.732 - 0.364)} = 35.789 = 35.79 \text{ m/s.}$$

From equation (*i*), $V_{f_1} = 0.364 \times V_{w_1} = 0.364 \times 35.79 = 13.027$ m/s.

(*a*) Volume flow rate is given by equation (18.21) as $Q = \pi D_1 B_1 \times V_{f_1}$

But
$$\pi D_1 \times B_1 = 0.4 \text{ m}^2 \qquad \text{(given)}$$

$$Q = 0.4 \times 13.027 = \mathbf{5.211\ m^3/s.\ Ans.}$$

(*b*) Work done per sec on the turbine is given by equation (18.18),

$$= \rho Q\ [V_{w_1} u_1] \qquad (\because \quad V_{w_2} = 2)$$

$$= 1000 \times 5.211\ [35.79 \times 28.27] = 5272402 \text{ Nm/s}$$

$$\therefore \quad \text{Power developed in kW} = \frac{\text{Work done per second}}{1000} = \frac{5272402}{1000} = \mathbf{5272.402\ kW.\ Ans.}$$

(*c*) The hydraulic efficiency is given by equation (18.20*B*) as

$$\eta_h = \frac{V_{w_1} u_1}{gH} = \frac{35.79 \times 28.27}{9.81 \times 120} = 0.8595 = \mathbf{85.95\%.\ Ans.}$$

Problem 18.17 *As inward flow reaction turbine has external and internal diameters as 1.0 m and 0.6 m respectively. The hydraulic efficiency of the turbine is 90% when the head on the turbine is 36 m. The velocity of flow at outlet is 2.5 m/s and discharge at outlet is radial. If the vane angle at outlet is 15° and width of the wheel is 100 mm at inlet and outlet, determine : (i) the guide blade angle, (ii) speed of the turbine, (iii) vane angle of the runner at inlet, (iv) volume flow rate of turbine and (v) power developed.*

Solution. Given :

External diameter, $D_1 = 1.0$ m

Internal diameter, $D_2 = 0.6$ m
Hydraulic efficiency, $\eta_h = 90\% = 0.90$
Head, $H = 36$ m
Velocity of flow at outlet, $V_{f_2} = 2.5$ m/s
Discharge is radial, $V_{w_2} = 0$
Vane angle at outlet, $\phi = 15°$
Width of wheel, $B_1 = B_2 = 100$ mm $= 0.1$ m

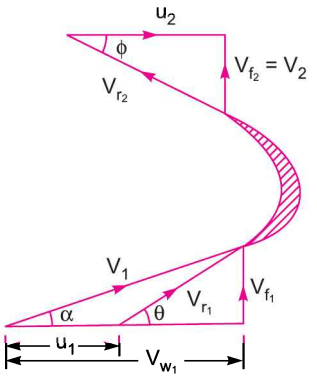

Fig. 18.14

Using equation (18.20 *B*) for hydraulic efficiency as

$$\eta_h = \frac{V_{w_1} u_1}{gH} \text{ or } 0.90 = \frac{V_{w_1} . u_1}{9.81 \times 36}$$

$$\therefore \quad V_{w_1} u_1 = 0.90 \times 9.81 \times 36 = 317.85 \qquad ...(i)$$

From outlet velocity triangle, $\tan \phi = \frac{V_{f_2}}{u_2} = \frac{2.5}{u_2}$

$$\therefore \quad u_2 = \frac{2.5}{\tan \phi} = \frac{2.5}{\tan 15°} = 9.33$$

But $$u_2 = \frac{\pi D_2 N}{60} = \frac{\pi \times 0.6 \times N}{60}$$

$$\therefore \quad 9.33 = \frac{\pi \times 0.6 \times N}{60} \text{ or } N = \frac{60 \times 9.33}{\pi \times 0.6} = \mathbf{296.98.\ Ans.}$$

$$\therefore \quad u_1 = \frac{\pi \times D_1 \times N}{60} = \frac{\pi \times 1.0 \times 296.98}{60} = 15.55 \text{ m/s.}$$

Substituting this value of 'u_1' in equation (*i*),

$$V_{w_1} \times 15.55 = 317.85$$

$$\therefore \quad V_{w_1} = \frac{317.85}{15.55} = 20.44 \text{ m/s}$$

Using equation (18.21), $\pi D_1 B_1 V_{f_1} = \pi D_2 B_2 V_{f_2}$ or $D_1 V_{f_1} = D_2 V_{f_2}$ $(\because \ B_1 = B_2)$

$$\therefore \quad V_{f_1} = \frac{D_2 \times V_{f_2}}{D_1} = \frac{0.6 \times 2.5}{1.0} = 1.5 \text{ m/s.}$$

(*i*) *Guide blade angle* (α).

From inlet velocity triangle, $\tan \alpha = \frac{V_{f_1}}{V_{w_1}} = \frac{1.5}{20.44} = 0.07338$

$$\therefore \quad \alpha = \tan^{-1} 0.07338 = \mathbf{4.19°} \text{ or } \mathbf{4° 11.8'.\ Ans.}$$

(*ii*) *Speed of the turbine,* $N = \mathbf{296.98\ r.p.m.\ Ans.}$

(*iii*) *Same angle of runner at inlet* (θ)

$$\tan\theta = \frac{V_{f_1}}{V_{w_1} - u_1} = \frac{1.5}{(20.44 - 15.55)} = 0.3067$$

$\therefore$ $\theta = \tan^{-1} .3067 = 17.05°$ or **17° 3′. Ans.**

(*iv*) *Volume flow rate of turbine* is given by equation (18.21) as

$$= \pi D_1 B_1 V_{f_1} = \pi \times 1.0 \times 0.1 \times 1.5 = \mathbf{0.4712\ m^3/s.\ Ans.}$$

(*v*) *Power developed* (in kW)

$$= \frac{\text{Work done per second}}{1000} = \frac{\rho Q \left[V_{w_1} u_1\right]}{1000}$$

[Using equation (18.18) and $V_{w_2} = 0$]

$$= 1000 \times \frac{0.4712 \times 20.44 \times 15.55}{1000} = \mathbf{149.76\ kW.\ Ans.}$$

Problem 18.18 *An inward flow reaction turbine has an exit diameter of 1 metre and its breadth at inlet is 250 mm. If the velocity of flow at inlet is 2 metres/s, find the mass of water passing through the turbine per second. Assume 10% of the area of flow is blocked by blade thickness. If the speed of the runner is 210 r.p.m. and guide blades make an angle of 10° to the wheel tangent, draw the inlet velocity triangle, and find :*

(i) the runner vane angle at inlet, (ii) velocity of wheel at inlet,
(iii) the absolute velocity of water leaving the guide vanes, and
(iv) the relative velocity of water entering the runner blade.

Solution. Given :

Exit or External diameter, $D_1 = 1.0$ m

Breadth at inlet, $B_1 = 250$ mm $= 0.25$ m

Velocity of flow at inlet, $V_{f_1} = 2.0$ m/s

Area blocked by vanes $= 10\%$

Speed, $N = 210$ r.p.m.

Guide blade angle, $\alpha = 10°$

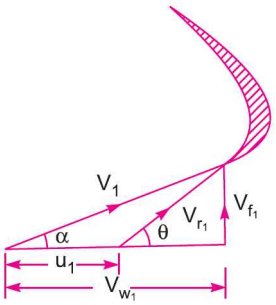

Fig. 18.15

Tangential velocity of wheel at inlet,

$$u_1 = \frac{\pi D_1 N}{60} = \frac{\pi \times 1.0 \times 210}{60} = 10.99 \text{ m/s}$$

$$\text{Area blocked by vane thickness} = \frac{10}{100} \times \pi D_1 B_1 = 0.1\ \pi D_1 B_1$$

$\therefore$ Actual area through which flow takes place,

$$a = \pi D_1 B_1 - 0.1\ \pi D_1 B_1 = 0.9 \pi D_1 B_1$$
$$= 0.9 \times \pi \times 1.0 \times 0.25 = 0.7068\ \text{m}^2$$

$\therefore$ Mass of water passing per second

$$= \rho \times a \times V_{f_1} = 1000 \times .7068 \times 2.0 = \mathbf{1413.6\ kg.\ Ans.}$$

(*i*) *The runner vane angle at inlet* (θ).

From inlet velocity triangle $\tan \alpha = \dfrac{V_{f_1}}{V_{w_1}} = \dfrac{2.0}{V_{w_1}}$

$$\therefore \quad V_{w_1} = \frac{2.0}{\tan \alpha} = \frac{2.0}{\sin 10} = 11.34 \text{ m/s}$$

$$\therefore \quad \tan \theta = \frac{V_{f_1}}{V_{w_1} - u_1} = \frac{2.0}{11.34 - 10.99} = 5.714$$

$$\therefore \quad \theta = \tan^{-1} 5.714 = \mathbf{80.07°} \text{ or } \mathbf{80°4.2'. Ans.}$$

(*ii*) *Velocity of wheel at inlet,* $u_1 = \mathbf{10.99 \text{ m/s. Ans.}}$

(*iii*) *The absolute velocity of water leaving the guide vanes* (V_1) :

From inlet triangle, $\sin \alpha = \dfrac{V_{f_1}}{V_1}$

$$\therefore \quad V_1 = \frac{V_{f_1}}{\sin \alpha} = \frac{2.0}{\sin 10°} = \mathbf{11.517 \text{ m/s. Ans.}}$$

(*iv*) *The relative velocity of water entering the runner blade* (V_{r_1})

$$\sin \theta = \frac{V_{f_1}}{V_{r_1}}$$

$$\therefore \quad V_{r_1} = \frac{V_{f_1}}{\sin \theta} = \frac{2.0}{\sin 80.07°} = \mathbf{2.03 \text{ m/s. Ans.}}$$

Problem 18.19 *The external and internal diameters of an inward flow reaction turbines are 1.20 m and 0.6 m respectively. The head on the turbine is 22 m and velocity of flow through the runner is constant and equal to 2.5 m/s. The guide blade angle is given as 10° and the runner vanes are radial at inlet. If the discharge at outlet is radial, determine :*

(i) The speed of the turbine, (ii) The vane angle at outlet of the runner, and

(iii) Hydraulic efficiency.

Solution. Given :

External diameter, $D_1 = 1.20$ m

Internal diameter, $D_2 = 0.60$ m

Head, $H = 22.0$ m

Velocity of flow, $V_{f_1} = V_{f_2} = 2.5$ m/s

Guide blade angle, $\alpha = 10°$

Runner vanes radial at inlet means, $\theta = 90°$

$$\therefore \quad V_{w_1} = u_1, V_{r_1} = V_{f_1} = 2.5 \text{ m/s}$$

Discharge is radial

$$\therefore \quad V_{w_2} = 0, V_2 = V_{f_2} = 2.5 \text{ m/s}$$

From inlet velocity triangle,

$$\tan \alpha = \frac{V_{f_1}}{u_1}$$

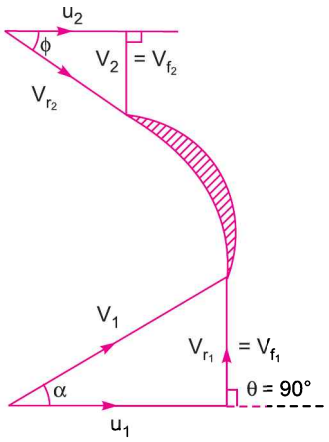

Fig. 18.16

$$\therefore \quad u_1 = \frac{V_{f_1}}{\tan \alpha} = \frac{1.5}{\tan 10^\circ} = 14.178 \text{ m/s}$$

$$\therefore \quad V_{w_1} = u_1 = 14.178 \text{ m/s}$$

(*i*) *The speed of the turbine* (N)

Using $$u_1 = \frac{\pi D_1 \times N}{60}$$

$$\therefore \quad N = \frac{60 \times u_1}{\pi D_1} = \frac{60 \times 14.178}{\pi \times 1.20} = \textbf{225.65 r.p.m. Ans.}$$

(*ii*) *The vane angle at outlet of the runner* (ϕ).

$$u_2 = \frac{\pi D_2 \times N}{60} = \frac{\pi \times 0.6 \times 225.65}{60} = 7.09 \text{ m/s.}$$

From outlet velocity triangle, $\tan \phi = \frac{V_{f_2}}{u_2} = \frac{2.5}{7.09} = 0.3526$

$$\therefore \quad \phi = \tan^{-1} 0.3526 = 19.42^\circ \text{ or } \textbf{19° 25.2′. Ans.}$$

(*iii*) *Hydraulic efficiency* is given by $\eta_h = \frac{V_{w_1} u_1}{gH} = \frac{14.178 \times 14.178}{9.81 \times 22.0} = 0.9314 = \textbf{93.14\%. Ans.}$

Problem 18.20 *233 litres of water per second are supplied to an inward flow reaction turbine. The head available is 11 m. The wheel vanes are radial at inlet and the inlet diameter is twice the outlet diameter. The velocity of flow is constant and equal to 1.83 m/s. The wheel makes 370 r.p.m. Find :*

(a) Guide vane angle, (b) Inlet and outlet diameter of the wheel,

(c) The width of the wheel at inlet and exit. Neglect the thickness of the vanes.

Assume that the discharge is radial and there are no losses in the wheel. Take speed ratio = 0.7.

Solution. Given :

Discharge, $Q = 233 \text{ lit/s} = 0.233 \text{ m}^3/\text{s}$

Head, $H = 11 \text{ m}$

Wheel vanes are radial at inlet. This means angle

$$\theta = 90^\circ \text{ and } V_{r_1} = V_{f_1}$$

Inlet diameter $= 2 \times$ Outlet diameter

$$\therefore \quad D_1 = 2D_2$$

Velocity of flow at inlet and outlet = 1.83 m/s

$$\therefore \quad V_{f_1} = V_{f_2} = 1.83 \text{ m/s}$$

Speed, $N = 370$ r.p.m.

Speed ratio $= 0.7$ or $\frac{u_1}{\sqrt{2gH}} = 0.7$

$$\therefore \quad u_1 = 0.7 \times \sqrt{2gH}$$

$$= 0.7 \times \sqrt{2 \times 9.81 \times 11} = 10.28 \text{ m/s}$$

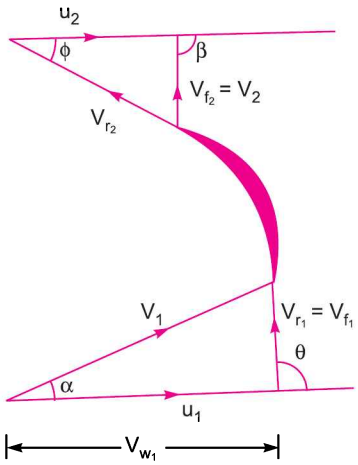

Fig. 18.17

Discharge is radial at outlet. This means angle $\beta = 90^\circ$ and $V_{w_2} = 0$

(*a*) *Guide vane angle* (α)

$$\tan \alpha = \frac{V_{f_1}}{u_1} = \frac{1.83}{10.28} = 0.178$$

$$\therefore \quad \alpha = \tan^{-1} .178 = \mathbf{10° 6'. Ans.}$$

(*b*) *Inlet and outlet diameter of the wheel*

$$u_1 = \frac{\pi D_1 N}{60} = \frac{\pi \times D_1 \times 370}{60}$$

$$\therefore \quad D_1 = \frac{60 \times u_1}{\pi \times 370} = \frac{60 \times 10.28}{\pi \times 370} = .532 \text{ m} = \mathbf{53.2 \text{ cm. Ans.}}$$

$$D_2 = \frac{D_1}{2} = \frac{53.2}{2} = \mathbf{26.6 \text{ cm. Ans.}}$$

(*c*) *Width of wheel at inlet and outlet*

$$Q = \pi D_1 \times B_1 \times V_{f_1} = \pi D_2 \times B_2 \times V_{f_2}$$

But $V_{f_1} = V_{f_2} \quad \therefore \quad D_1 \times B_1 = D_2 \times B_2$

As $D_1 = 2D_2, B_2 = 2B_1$

Now $Q = \pi D_1 \times B_1 \times V_{f_1} = \pi \times .532 \times B_1 \times 1.83$

$$\therefore \quad B_1 = \frac{Q}{\pi \times .532 \times 1.83} = \frac{0.233}{\pi \times .532 \times 1.83} = 0.0762 \text{ m} = \mathbf{7.62 \text{ cm. Ans.}}$$

$$B_2 = 2 \times B_1 = 2 \times 7.62 = \mathbf{15.24 \text{ cm. Ans.}}$$

18.7.5 Outward Radial Flow Reaction Turbine. Fig. 18.18 shows outward radial flow reaction turbine in which the water from casing enters the stationary guide wheel. The guide wheel consists of guide

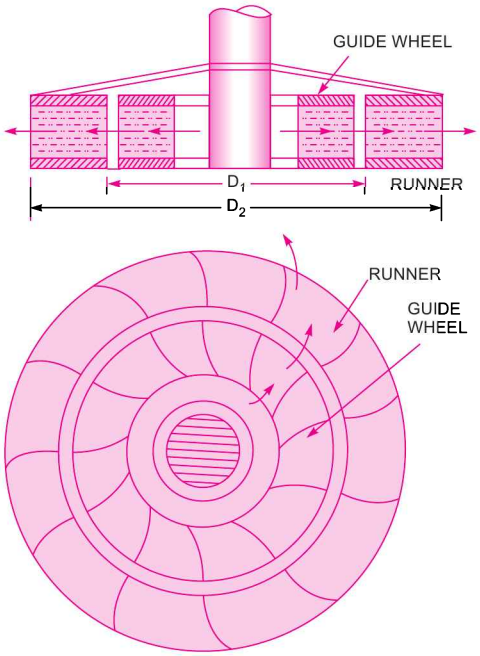

Fig. 18.18 *Outward radial flow turbine.*

vanes which direct water to enter the runner which is around the stationary guide wheel. The water flows through the vanes of the runner in the outward radial direction and is discharged at the outer diameter of the runner. The inner diameter of the runner is inlet and outer diameter is the outlet.

The velocity triangles at inlet and outlet will be drawn by the same procedure as adopted for inward flow turbine. The work done by the water on the runner per second, the horse power developed and hydraulic efficiency will be obtained from the velocity triangles. In this case as inlet of the runner is at the inner diameter of the runner, the tangential velocity at inlet will be less than that of at outlet, *i.e.*,

$$u_1 < u_2 \text{ as } D_1 < D_2.$$

Problem 18.21 *An outward flow reaction turbine has internal and external diameters of the runner as 0.6 m and 1.2 m respectively. The guide blade angle is 15° and velocity of flow through the runner is constant and equal to 4 m/s. If the speed of the turbine is 200 r.p.m., head on the turbine is 10 m and discharge at outlet is radial, determine :*

(i) The runner vane angles at inlet and outlet,

(ii) Work done by the water on the runner per second per unit weight of water striking per second ,

(iii) Hydraulic efficiency, and

(iv) The degree of reaction.

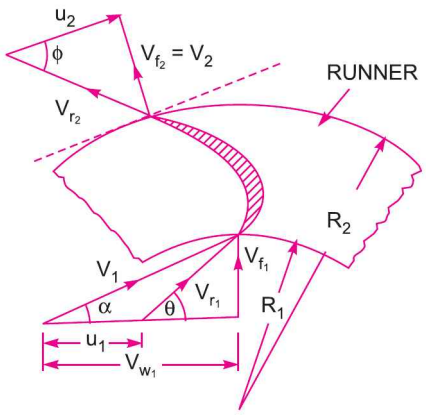

Fig. 18.19

Solution. Given :

Internal diameter,	$D_1 = 0.6$ m
External diameter,	$D_2 = 1.2$ m
Guide blade angle,	$\alpha = 15°$
Velocity of flow,	$V_{f_1} = V_{f_2} = 4$ m/s
Speed,	$N = 200$ r.p.m.
Head,	$H = 10$ m
Discharge at outlet	= Radial
$\therefore$	$V_{w_2} = 0$, $V_{f_2} = V_2$

Tangential velocity of runner at inlet and outlet are :

$$u_1 = \frac{\pi D_1 N}{60} = \frac{\pi \times 0.6 \times 200}{60} = 6.283 \text{ m/s}$$

$$u_2 = \frac{\pi D_2 N}{60} = \frac{\pi \times 1.2 \times 200}{60} = 12.566 \text{ m/s.}$$

From the inlet velocity triangle, $\tan \alpha = \dfrac{V_{f_1}}{V_{w_1}}$

$$\therefore \quad V_{w_1} = \frac{V_{f_1}}{\tan \alpha} = \frac{4.0}{\tan 15^\circ} = 14.928 \text{ m/s.}$$

(*i*) *Runner Vane Angles at inlet and outlet* are θ and ϕ

$$\tan \theta = \frac{V_{f_1}}{V_{w_1} - u_1} = \frac{4.0}{(14.928 - 6.283)} = 0.4627$$

$$\theta = \tan^{-1} .4627 = 24.83 \text{ or } \mathbf{24° 49.8'. Ans.}$$

From outlet velocity triangle, $\tan \phi = \frac{V_{f_2}}{u_2} = \frac{4.0}{12.566} = 0.3183$

$\therefore$ $\phi = \tan^{-1} .3183 =$ **17.65° or 17° 39.4′. Ans.**

(*ii*) *Work done by water per second per unit weight of water striking per second*

$$= \frac{1}{g} V_{w_1} u_1 \qquad (\because \ V_{w_2} = 0)$$

$$= \frac{1}{9.81} \times 14.928 \times 6.283 = \textbf{9.561 Nm/N. Ans.}$$

(*iii*) *Hydraulic efficiency* is given by equation (18.20*B*) as

$$\eta_h = \frac{V_{w_1} u_1}{gH} = \frac{14.928 \times 6.283}{9.81 \times 10} = \textbf{0.9561 or 95.61\%. Ans.}$$

(*iv*) Given : In this question, the velocity of flow is constant through the runner (*i.e.*, $V_{f_1} = V_{f_2}$) and the discharge is radial at outlet (*i.e.*, $\beta = 90°$ or $V_{w_2} = 0$), the degree of reaction (R) is given by equation (18.20*I*) as

$$R = 1 - \frac{\cot \alpha}{2 (\cot \alpha - \cot \theta)}$$

Here $\alpha = 13.928°$ and $\theta = 41.09°$ (calculated)

Substituting the value of α and θ, we get

$$R = 1 - \frac{\cot 13.928°}{2 (\cot 13.928° - \cot 41.09°)} = 1 - \frac{4.032}{2 (4.032 - 1.146)}$$

$$= 1 - 0.698 = 0.302 \simeq \textbf{0.3. Ans.}$$

For Francis turbine, the degree of reaction varies from 0 to 1 *i.e.*, $0 \le R \le 1$.

Problem 18.22 *The internal and external diameters of an outward flow reaction turbine are 2 m and 2.75 m respectively. The turbine is running at 250 r.p.m. and rate of flow of water through the turbine is 5 m^3/s. The width of the runner is constant at inlet and outlet and is equal to 250 mm. The head on the turbine is 150 m. Neglecting thickness of the vanes and taking discharge radial at outlet determine :*

(i) Vane angles at inlet and outlet, and

(ii) Velocity of flow at inlet and outlet.

Solution. Given :

Internal diameter,	$D_1 = 2.0$ m
External diameter,	$D_2 = 2.75$ m
Speed of turbine,	$N = 250$ r.p.m.
Discharge,	$Q = 5$ m^3/s
Width at inlet and outlet,	$B_1 = B_2 = 250$ mm $= 0.25$ m
Head,	$H = 150$ m
Discharge at outlet	= radial

$\therefore$ $V_{w_2} = 0$ and $V_{f_2} = V_2$.

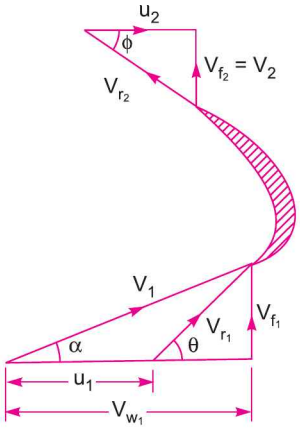

Fig. 18.20

The tangential velocity of the turbine at inlet and outlet,

$$u_1 = \frac{\pi D_1 N}{60} = \frac{\pi \times 2.0 \times 250}{60} = 26.18 \text{ m/s}$$

$$u_2 = \frac{\pi D_2 N}{60} = \frac{\pi \times 2.75 \times 250}{60} = 36.0 \text{ m/s.}$$

The discharge through turbine is given by equation (18.21) as

$$Q = \pi D_1 B_1 V_{f_1} = \pi D_2 B_2 V_{f_2}$$

$$\therefore \quad V_{f_1} = \frac{Q}{\pi D_1 B_1} = \frac{5.0}{\pi \times 2.0 \times .25} = 3.183 \text{ m/s.}$$

And $$V_{f_2} = \frac{Q}{\pi D_2 B_2} = \frac{5.0}{\pi \times 2.75 \times .25} = 2.315 \text{ m/s}$$

Using equation (18.24), $H - \frac{V_2^2}{2g} = \frac{V_{w_1} u_1}{g}$ $\left(\because \ V_{w_2} = 0\right)$

But for radial discharge, $V_2 = V_{f_2} = 2.315$ m/s

$$\therefore \quad 150 - \frac{2.315^2}{2 \times 9.81} = \frac{V_{w_2} \times 26.18}{9.81} \text{ or } 149.73 = \frac{V_{w_1} \times 26.18}{9.81}$$

$$\therefore \quad V_{w_1} = \frac{149.73 \times 9.81}{26.18} = 56.1 \text{ m/s.}$$

(*i*) *Vane angles at inlet and outlet*

From inlet velocity triangle, $\tan \theta = \frac{V_{f_1}}{V_{w_1} - u_1} = \frac{3.183}{56.1 - 26.18} = 0.1064$

$$\therefore \quad \theta = \tan^{-1} .1064 = \mathbf{6.072°} \text{ or } \mathbf{6° \ 4.32'. \ Ans.}$$

From outlet velocity triangle, $\tan \phi = \frac{V_{f_2}}{u_2} = \frac{2.315}{36.0} = 0.0643$

$$\therefore \quad \phi = \tan^{-1} .0643 = \mathbf{3.68°} \text{ or } \mathbf{3° \ 40.8'. \ Ans.}$$

(*ii*) *Velocity of flow at inlet and outlet*

$$V_{f_1} = 3.183 \text{ m/s and } V_{f_2} = \mathbf{2.315 \text{ m/s. Ans.}}$$

▶ 18.8 FRANCIS TURBINE

The inward flow reaction turbine having radial discharge at outlet is known as Francis Turbine, after the name of J.B. Francis, an American engineer who in the beginning designed inward radial flow reaction type of turbine. In the modern Francis turbine, the water enters the runner of the turbine in the radial direction at outlet and leaves in the axial direction at the inlet of the runner. Thus the modern Francis Turbine is a mixed flow type turbine.

The velocity triangle at inlet and outlet of the Francis turbine are drawn in the same way as in case of inward flow reaction turbine. As in case of Francis turbine, the discharge is radial at outlet, the velocity of whirl at outlet (*i.e.*, V_{w_2}) will be zero. Hence the work done by water on the runner per second will be

$$= \rho Q[V_{w_1} u_1]$$

And work done per second per unit weight of water striking/s = $\frac{1}{g}\left[V_{w_1} u_1\right]$

Hydraulic efficiency will be given by, $\eta_h = \frac{V_{w_1} u_1}{gH}$.

18.8.1 Important Relations for Francis Turbines. The following are the important relations for Francis Turbines :

1. The ratio of width of the wheel to its diameter is given as $n = \frac{B_1}{D_1}$. The value of n varies from 0.10 to .40.

2. The flow ratio is given as,

Flow ratio = $\frac{V_{f_1}}{\sqrt{2gH}}$ and varies from 0.15 to 0.30.

3. The speed ratio = $\frac{u_1}{\sqrt{2gH}}$ varies from 0.6 to 0.9.

Problem 18.23 *A Francis turbine with an overall efficiency of 75% is required to produce 148.25 kW power. It is working under a head of 7.62 m. The peripheral velocity = 0.26* $\sqrt{2gH}$ *and the radial velocity of flow at inlet is 0.96* $\sqrt{2gH}$. *The wheel runs at 150 r.p.m. and the hydraulic losses in the turbine are 22% of the available energy. Assuming radial discharge, determine :*

(i) The guide blade angle, *(ii) The wheel vane angle at inlet,*
(iii) Diameter of the wheel at inlet, and *(iv) Width of the wheel at inlet.*

Solution. Given :

Overall efficiency $\eta_o = 75\% = 0.75$

Power produced, S.P. = 148.25 kW

Head, $H = 7.62$ m

Peripheral velocity, $u_1 = 0.26\sqrt{2gH} = 0.26 \times \sqrt{2 \times 9.81 \times 7.62} = 3.179$ m/s

Velocity of flow at inlet, $V_{f_1} = 0.96\sqrt{2gH} = 0.96 \times \sqrt{2 \times 9.81 \times 7.62} = 11.738$ m/s.

Speed, $N = 150$ r.p.m.

Hydraulic losses = 22% of available energy

Discharge at outlet = Radial

$V_{w_2} = 0$ and $V_{f_2} = V_2$

Hydraulic efficiency is given as

$$\eta_h = \frac{\text{Total head at inlet} - \text{Hydraulic loss}}{\text{Head at inlet}}$$

$$= \frac{H - .22\,H}{H} = \frac{0.78\,H}{H} = 0.78$$

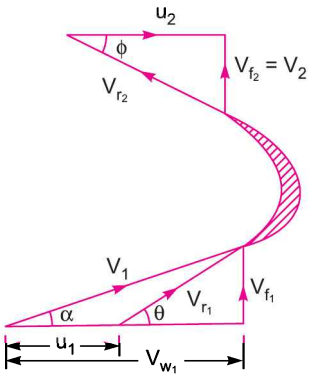

Fig. 18.21

But $$\eta_h = \frac{V_{w_1} u_1}{gH}$$

$$\therefore \quad \frac{V_{w_1} u_1}{gH} = 0.78$$

$$\therefore \quad V_{w_1} = \frac{0.78 \times g \times H}{u_1}$$

$$= \frac{0.78 \times 9.81 \times 7.62}{3.179} = 18.34 \text{ m/s.}$$

(*i*) *The guide blade angle, i.e.*, α. From inlet velocity triangle,

$$\tan \alpha = \frac{V_{f_1}}{V_{w_1}} = \frac{11.738}{18.34} = 0.64$$

$$\therefore \quad \alpha = \tan^{-1} 0.64 = \mathbf{32.619°} \text{ or } \mathbf{32° 37'. Ans.}$$

(*ii*) *The wheel vane angle at inlet, i.e.*, θ

$$\tan \theta = \frac{V_{f_1}}{V_{w_1} - u_1} = \frac{11.738}{18.34 - 3.179} = 0.774$$

$$\therefore \quad \theta = \tan^{-1} .774 = \mathbf{37.74} \text{ or } \mathbf{37° 44.4'. Ans.}$$

(*iii*) *Diameter of wheel at inlet* (D_1).

Using the relation, $$u_1 = \frac{\pi D_1 N}{60}$$

$$D_1 = \frac{60 \times u_1}{\pi \times N} = \frac{60 \times 3.179}{\pi \times 50} = \mathbf{0.4047 \text{ m. Ans.}}$$

(*iv*) *Width of the wheel at inlet* (B_1)

$$\eta_o = \frac{\text{S.P.}}{\text{W.P.}} = \frac{148.25}{\text{W.P.}}$$

But $$\text{W.P.} = \frac{\text{WH}}{1000} = \frac{\rho \times g \times Q \times H}{1000} = \frac{1000 \times 9.81 \times Q \times 7.62}{1000}$$

$$\therefore \quad \eta_o = \frac{148.25}{\frac{1000 \times 9.81 \times Q \times 7.62}{1000}} = \frac{148.25 \times 1000}{1000 \times 9.81 \times Q \times 7.62}$$

or $$Q = \frac{148.25 \times 1000}{1000 \times 9.81 \times 7.62 \times \eta_o} = \frac{148.25 \times 1000}{1000 \times 9.81 \times 7.62 \times 0.75} = 2.644 \text{ m}^3/\text{s}$$

Using equation (18.21), $$Q = \pi D_1 \times B_1 \times V_{f_1}$$

$\therefore \quad 2.644 = \pi \times .4047 \times B_1 \times 11.738$

$\therefore \quad B_1 = \dfrac{2.644}{\pi \times .4047 \times 11.738} = \mathbf{0.177\ m.\ Ans.}$

Problem 18.24 *The following data is given for a Francis Turbine. Net head H = 60 m ; Speed N = 700 r.p.m.; shaft power = 294.3 kW ; η_o = 84% ; η_h = 93%; flow ratio = 0.20 ; breadth ratio n = 0.1; Outer diameter of the runner = 2 × inner diameter of runner. The thickness of vanes occupy 5% of circumferential area of the runner, velocity of flow is constant at inlet and outlet and discharge is radial at outlet. Determine :*

(i) Guide blade angle, *(ii) Runner vane angles at inlet and outlet,*

(iii) Diameters of runner at inlet and outlet, and *(iv) Width of wheel at inlet.*

Solution. Given :

Net head, $H = 60$ m

Speed, $N = 700$ r.p.m.

Shaft power $= 294.3$ kW

Overall efficiency, $\eta_o = 84\% = 0.84$

Hydraulic efficiency, $\eta_h = 93\% = 0.93$

Flow ratio, $\dfrac{V_{f_1}}{\sqrt{2gH}} = 0.20$

$\therefore \quad V_{f_1} = 0.20 \times \sqrt{2gH}$

$= 0.20 \times \sqrt{2 \times 9.81 \times 60} = 6.862$ m/s

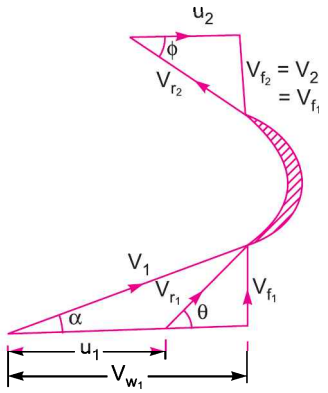

Fig. 18.22

Breadth ratio, $\dfrac{B_1}{D_1} = 0.1$

Outer diameter, $D_1 = 2 \times$ Inner diameter $= 2 \times D_2$

Velocity of flow, $V_{f_1} = V_{f_2} = 6.862$ m/s.

Thickness of vanes $=$ 5% of circumferential area of runner

$\therefore$ Actual area of flow $= 0.95\ \pi D_1 \times B_1$

Discharge at outlet $=$ Radial

$\therefore \quad V_{w_2} = 0$ and $V_{f_2} = V_2$

Using relation, $\eta_o = \dfrac{\text{S.P.}}{\text{W.P.}}$

$0.84 = \dfrac{294.3}{\text{W.P.}}$

$\therefore \quad \text{W.P.} = \dfrac{294.3}{0.84} = 350.357$ kW.

But $\text{W.P.} = \dfrac{WH}{1000} = \dfrac{\rho \times g \times Q \times H}{1000} = \dfrac{1000 \times 9.81 \times Q \times 60}{1000}$

$\therefore \quad \dfrac{1000 \times 9.81 \times Q \times 60}{1000} = 350.357$

$$\therefore \quad Q = \frac{350.357 \times 1000}{60 \times 1000 \times 9.81} = 0.5952 \text{ m}^3/\text{s}.$$

Using equation (18.21), Q = Actual area of flow × Velocity of flow

$$= 0.95\ \pi D_1 \times B_1 \times V_{f_1}$$

$$= 0.95 \times \pi \times D_1 \times 0.1 D_1 \times V_{f_2} \qquad (\because \quad B_1 = 0.1\ D_1)$$

or $$0.5952 = 0.95 \times \pi \times D_1 \times 0.1 \times D_1 \times 6.862 = 2.048\ D_1^2$$

$$\therefore \quad D_1 = \sqrt{\frac{0.5952}{2.048}} = 0.54 \text{ m}$$

But $$\frac{B_1}{D_1} = 0.1$$

$$\therefore \quad B_1 = 0.1 \times D_1 = 0.1 \times .54 = .054 \text{ m} = 54 \text{ mm}$$

Tangential speed of the runner at inlet,

$$u_1 = \frac{\pi D_1 N}{60} = \frac{\pi \times 0.54 \times 700}{60} = 19.79 \text{ m/s}.$$

Using relation for hydraulic efficiency,

$$\eta_h = \frac{V_{w_1} u_1}{gH} \text{ or } 0.93 = \frac{V_{w_1} \times 19.79}{9.81 \times 60}$$

$$\therefore \quad V_{w_1} = \frac{0.93 \times 9.81 \times 60}{19.79} = 27.66 \text{ m/s}.$$

(*i*) *Guide blade angle* (α)

From inlet velocity triangle, $\tan \alpha = \frac{V_{f_1}}{V_{w_1}} = \frac{6.862}{27.66} = 0.248$

$$\therefore \quad \alpha = \tan^{-1} 0.248 = 13.928° \text{ or } \mathbf{13° 55.7'. Ans.}$$

(*ii*) *Runner vane angles at inlet and outlet (θ and ϕ)*

$$\tan \theta = \frac{V_{f_1}}{V_{w_1} - u_1} = \frac{6.862}{27.66 - 19.79} = 0.872$$

$$\therefore \quad \theta = \tan^{-1} 0.872 = 41.09° \text{ or } \mathbf{41° 5.4'. Ans.}$$

From outlet velocity triangle, $\tan \phi = \frac{V_{f_2}}{u_2} = \frac{V_{f_1}}{u_2} = \frac{6.862}{u_2}$ ...(*i*)

But $$u_2 = \frac{\pi D_2 N}{60} = \frac{\pi \times D_1}{2} \times \frac{N}{60} \qquad \left(\because \quad D_2 = \frac{D_1}{2} \text{ given}\right)$$

$$= \pi \times \frac{.54}{2} \times \frac{700}{60} = 9.896 \text{ m/s}.$$

Substituting the value of u_2 in equation (*i*),

$$\tan \phi = \frac{6.862}{9.896} = 0.6934$$

$\therefore$ $\phi = \tan^{-1} .6934° = 34.74$ or **34° 44.4′. Ans.**

(*iii*) *Diameters of runner at inlet and outlet*

$D_1 = 0.54$ m, $D_2 = \mathbf{0.27\ m.}$ **Ans.**

(*iv*) *Width of wheel at inlet*

$B_1 = \mathbf{54\ mm.}$ **Ans.**

Problem 18.24 (A) *For the above problem, find the degree of reaction for the given Francis Turbine.*

Solution. Given :

In this question, the velocity of flow is constant through the runner (*i.e.*, $V_{f_1} = V_{f_2}$) and the discharge is radial at outlet (*i.e.*, $\beta = 90°$ or $V_{w_2} = 0$), the degree of reaction (R) is given by equation (18.20 *I*) as

$$R = 1 - \frac{\cot \alpha}{2(\cot \alpha - \cot \theta)}$$

Here $\alpha = 13.928°$ and $\theta = 41.09°$ (calculated)

Substituting the value of α and θ, we get

$$R = 1 - \frac{\cot 13.928°}{2(\cot 13.928° - \cot 41.09°)} = 1 - \frac{4.032}{2(4.032 - 1.146)}$$

$$= 1 - 0.698 = 0.302 \simeq \mathbf{0.3.}$$ **Ans.**

For Francis Turbine, the degree of reaction varies from 0 to 1 *i.e.*, $0 \le R \le 1$.

Problem 18.25 *(a) Show that the hydraulic efficiency for a Francis turbine having velocity of flow through runner as constant, is given by the relation.*

$$\eta_h = \frac{1}{1 + \dfrac{\frac{1}{2}\tan^2 \alpha}{\left(1 - \dfrac{\tan \alpha}{\tan \theta}\right)}}$$

where α *= Guide blade angle and* θ *= Runner vane angle at inlet.*

The turbine is having radial discharge at outlet.

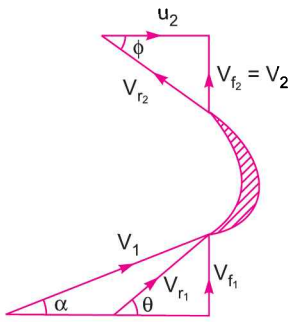

Fig. 18.23

(b) If vanes are radial at inlet, then show $\eta_h = \dfrac{2}{2 + \tan^2 \alpha}$.

Solution. Given :

Velocity of flow = Constant.

$\therefore$ $V_{f_1} = V_{f_2}$

Discharge is radial at outlet.

$\therefore$ $V_{w_2} = 0$ and $V_{f_2} = V_2$

(*a*) From the inlet velocity triangle,

$$\tan\alpha = \frac{V_{f_1}}{V_{w_1}} \quad \therefore \quad V_{f_1} = V_{w_1}\tan\alpha \qquad ...(i)$$

Also $$\tan\theta = \frac{V_{f_1}}{V_{w_1} - u_1}$$

or $$\left(V_{w_1} - u_1\right) = \frac{V_{f_1}}{\tan\theta} = \frac{V_{w_1}\tan\alpha}{\tan\theta} \qquad \left(\because \quad V_{f_1} = V_{w_1}\tan\alpha\right)$$

$$\therefore \qquad u_1 = V_{w_1} - \frac{V_{w_1}\tan\alpha}{\tan\theta} = V_{w_1}\left(1 - \frac{\tan\alpha}{\tan\theta}\right) \qquad ...(ii)$$

Using equation (18.24), we have

$$H - \frac{V_2^2}{2g} = \frac{1}{g}(V_{w_1}u_1) \qquad \left(\because \quad V_{w_2} = 0\right)$$

$$\therefore \qquad H = \frac{1}{g}V_{w_1}u_1 + \frac{V_2^2}{2g} = \frac{1}{g}V_{w_1}u_1 + \frac{V_{f_1}^2}{2g} \qquad \left(\because \quad V_2 = V_{f_2} = V_{f_1}\right)$$

Substituting the values of V_{f_1} and u_1 from equations (*i*) and (*ii*),

$$H = \frac{1}{g}V_{w_1} \times V_{w_1}\left(1 - \frac{\tan\alpha}{\tan\theta}\right) + \frac{\left[V_{w_1}\tan\alpha\right]^2}{2g}$$

$$= \frac{V_{w_1}^2}{g}\left(1 - \frac{\tan\alpha}{\tan\theta}\right) + \frac{V_{w_1}^2}{2g}\tan^2\alpha = \frac{V_{w_1}^2}{g}\left[1 - \frac{\tan\alpha}{\tan\theta} + \frac{\tan^2\alpha}{2}\right].$$

Now, hydraulic efficiency is given by

$$\eta_h = \frac{V_{w_1}u_1}{gH} = \frac{V_{w_1}u_1}{g \times \frac{V_{w_1}^2}{g}\left[1 - \frac{\tan\alpha}{\tan\theta} + \frac{\tan^2\alpha}{2}\right]}$$

$$= \frac{V_{w_1} \times V_{w_1}\left(1 - \frac{\tan\alpha}{\tan\theta}\right)}{V_{w_1}^2\left[1 - \frac{\tan\alpha}{\tan\theta} + \frac{\tan^2\alpha}{2}\right]} \qquad \left[\because \quad u_1 = V_{w_1}\left(1 - \frac{\tan\alpha}{\tan\theta}\right)\right]$$

$$= \frac{\left(1 - \frac{\tan\alpha}{\tan\theta}\right)}{\left[1 - \frac{\tan\alpha}{\tan\theta} + \frac{\tan^2\alpha}{2}\right]} = \frac{1}{1 + \frac{\frac{1}{2}\tan^2\alpha}{\left(1 - \frac{\tan\alpha}{\tan\theta}\right)}}.$$ **Ans.**

(*b*) If vanes are radial at inlet, then $\theta = 90°$

$$\therefore \quad \eta_h = \frac{1}{1+\dfrac{\frac{1}{2}\tan^2\alpha}{\left(1-\dfrac{\tan\alpha}{\tan 90°}\right)}} = \frac{1}{1+\dfrac{\frac{1}{2}\tan^2\alpha}{(1-0)}} = \frac{2}{2+\tan^2\alpha}. \textbf{ Ans.}$$

Problem 18.26 *A Francis turbine working under a head of 30 m has a wheel diameter of 1.2 m at the entrance and 0.6 m at the exit. The vane angle at the entrance is 90° and guide blade angle is 15°. The water at the exit leaves the vanes without any tangential velocity and the velocity of flow in the runner is constant. Neglecting the effect of draft tube and losses in the guide and runner passages, determine the speed of wheel in r.p.m. and vane angle at the exit. State whether the speed calculated is synchronous or not. If not, what speed would you recommend to couple the turbine with an alternator of 50 cycles ?*

Solution. Given :

Head on turbine, $H = 30$ m
Inlet dia., $D_1 = 1.2$ m
Outlet dia., $D_2 = 0.6$ m
Vane angle at inlet, $\theta = 90°$
Guide blade angle, $\alpha = 15°$

The water at exit leaves the vanes without any tangential velocity.

$\therefore \quad V_{w_2} = 0$ and $V_2 = V_{f_2}$

Velocity of flow is constant in runner.

$\therefore \quad V_{f_1} = V_{f_2}$

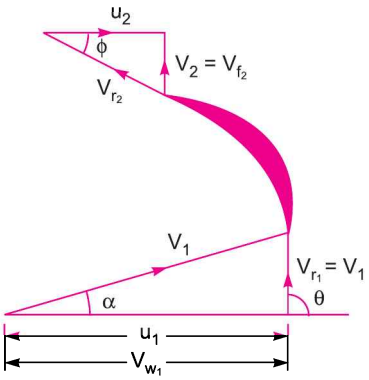

Fig. 18.24

(*i*) *Speed of turbine in r.p.m.*

Using equation (18.24), we have

$$H - \frac{V_2^2}{2g} = \frac{1}{g}\left(V_{w_1}u_1 \pm V_{w_2}u_2\right)$$

$$= \frac{1}{g}\left(V_{w_1} \times u_1\right) \qquad \left(\because \ V_{w_2} = 0\right)$$

$$= \frac{1}{g}u_1 \times u_1 \qquad \left(\because \ V_{w_1} = u_1\right)$$

or $$30 - \frac{V_{f_2}^2}{2g} = \frac{1}{g}u_1^2 \qquad \left(\because \ V_2 = V_{f_2} = V_{f_1}\right) \ ...(i)$$

But from inlet velocity triangle, we have

$$\tan\alpha = \frac{V_{f_1}}{u_1} \text{ or } u_1 = \frac{V_{f_1}}{\tan\alpha} = \frac{V_{f_1}}{\tan 15°} = 3.732\,V_{f_1} \qquad ...(ii)$$

Substituting the values of u_1 in equation (*i*), we get

$$30 - \frac{V_{f_2}^2}{2g} = \frac{1}{g} \times (3.732\ V_{f_1})^2 \text{ or } 30 - \frac{V_{f_1}^2}{2g} = \frac{13.928\,V_{f_2}^2}{g} \qquad \left(\because \ V_{f_2} = V_{f_1}\right)$$

or $$30 = \frac{14.928\, V_{f_1}^2}{g}$$

$$\therefore \quad V_{f_1} = \sqrt{\frac{30 \times 9.81}{14.928}} = 4.44 \text{ m/s.}$$

Substituting the value of V_{f_1} in equation (*ii*), we get

$$u_1 = 3.732 \times 4.44 = 16.57 \text{ m/s}$$

But $$u_1 = \frac{\pi D_1 N}{60} \text{ or } 16.57 = \frac{\pi \times 1.2 \times N}{60}$$

$$\therefore \quad N = \frac{16.57 \times 60}{\pi \times 1.2} = \textbf{263.72 r.p.m. Ans.}$$

(*ii*) *Vane angle at exit* (*i.e.*, ϕ)

$$u_2 = \frac{\pi D_2 \times N}{60} = \frac{\pi \times 0.6 \times 263.72}{60} = 8.285 \text{ m/s}$$

$$V_{f_2} = V_{f_1} = 4.44$$

Now, from velocity triangle at outlet,

$$\tan \phi = \frac{V_{f_2}}{u_2} = \frac{4.44}{8.285} = 0.5359$$

$$\therefore \quad \phi = \textbf{28.187°. Ans.}$$

(*iii*) For a turbine, which is directly coupled to the alternator of 50 cycles, the synchronous speed (N^*) is given by $$f = \frac{p.N^*}{60}$$

where f = Frequency of alternator in cycles/s, p = Number of pair of poles for the alternator.

Assuming the number of pair of poles = 12, we get

$$50 = \frac{12 \times N^*}{60}$$

$$\therefore \quad N^* = \frac{60 \times 50}{12} = 250 \text{ r.p.m.}$$

But the speed of turbine is 263.72. And synchronous speed (N^*) is equal to 250. Hence, the speed of turbine is not synchronous. The speed of turbine should be 250 r.p.m.

▶ 18.9 AXIAL FLOW REACTION TURBINE

If the water flows parallel to the axis of the rotation of the shaft, the turbine is known as axial flow turbine. And if the head at the inlet of the turbine is the sum of pressure energy and kinetic energy and during the flow of water through runner a part of pressure energy is converted into kinetic energy, the turbine is known as reaction turbine.

For the axial flow reaction turbine, the shaft of the turbine is vertical. The lower end of the shaft is made larger which is known as 'hub' or 'boss'. The vanes are fixed on the hub and hence hub acts as a runner for axial flow reaction turbine. The following are the important type of axial flow reaction turbines :

1. Propeller Turbine, and
2. Kaplan Turbine.

When the vanes are fixed to the hub and they are not adjustable, the turbine is known as propeller turbine. But if the vanes on the hub are adjustable, the turbine is known as a *Kaplan Turbine*, after the name of V Kaplan, an Austrian Engineer. This turbine is suitable where a large quantity of water at low head is available. Fig. 18.25 shows the runner of a Kaplan turbine, which consists of a hub fixed to the shaft. On the hub, the adjustable vanes are fixed as shown in Fig. 18.25.

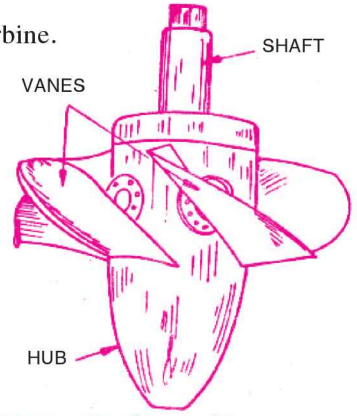

Fig. 18.25 *Kaplan turbine runner.*

The main parts of a Kaplan turbine are :

1. Scroll casing,
2. Guide vanes mechanism,
3. Hub with vanes or runner of the turbine, and
4. Draft tube.

Fig. 18.26 shows all main parts of a Kaplan turbine. The water from penstock enters the scroll casing and then moves to the guide vanes. From the guide vanes, the water turns through 90° and flows axially through the runner as shown in Fig. 18.26. The discharge through the runner is obtained as

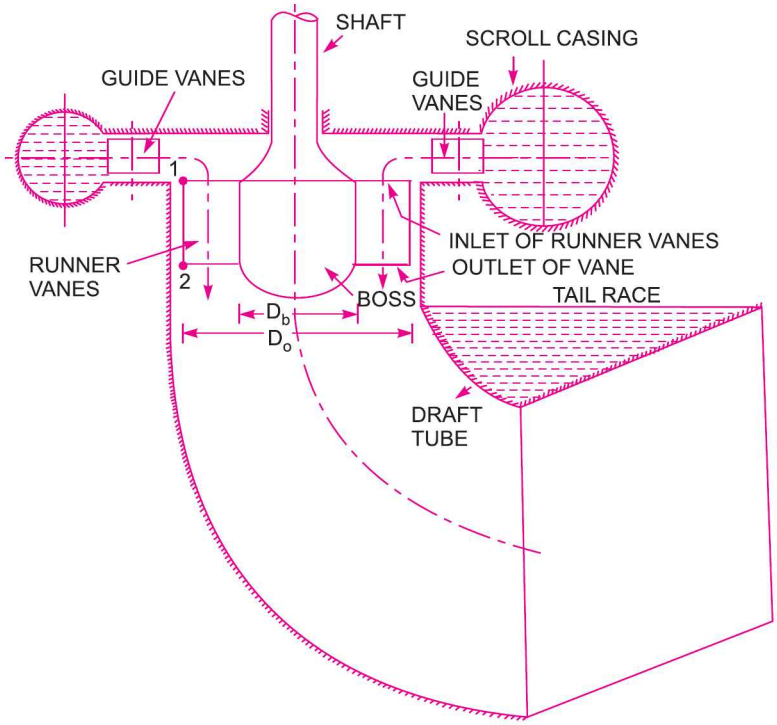

Fig. 18.26 *Main components of Kaplan turbine.*

$$Q = \frac{\pi}{4}\left(D_o^2 - D_b^3\right) \times V_{f_1} \qquad ...(18.25)$$

where D_o = Outer diameter of the runner,

D_b = Diameter of hub, and

V_{f_1} = Velocity of flow at inlet.

The inlet and outlet velocity triangles are drawn at the extreme edge of the runner vane corresponding to the points 1 and 2 as shown in Fig. 18.26.

18.9.1 Some Important Point for Propeller (Kaplan Turbine). The following are the important points for propeller or Kaplan turbine :

1. The peripheral velocity at inlet and outlet are equal

$$\therefore \qquad u_1 = u_2 = \frac{\pi D_o N}{60}, \text{ where } D_o = \text{Outer dia. of runner}$$

2. Velocity of flow at inlet and outlet are equal

$$\therefore \qquad V_{f_1} = V_{f_2}.$$

3. Area of flow at inlet = Area of flow at outlet

$$= \frac{\pi}{4}\left(D_o^2 - D_b^2\right).$$

Problem 18.27 *A Kaplan turbine working under a head of 20 m develops 11772 kW shaft power. The outer diameter of the runner is 3.5 m and hub diameter is 1.75 m. The guide blade angle at the extreme edge of the runner is 35°. The hydraulic and overall efficiencies of the turbines are 88% and 84% respectively. If the velocity of whirl is zero at outlet, determine :*

(i) Runner vane angles at inlet and outlet at the extreme edge of the runner, and

(ii) Speed of the turbine.

Solution. Given :

Head,	$H = 20$ m
Shaft power,	S.P. = 11772 kW
Outer dia. of runner,	$D_o = 3.5$ m
Hub diameter,	$D_b = 1.75$ m
Guide blade angle,	$\alpha = 35°$
Hydraulic efficiency,	$\eta_h = 88\%$
Overall efficiency,	$\eta_o = 84\%$
Velocity of whirl at outlet	$= 0$.

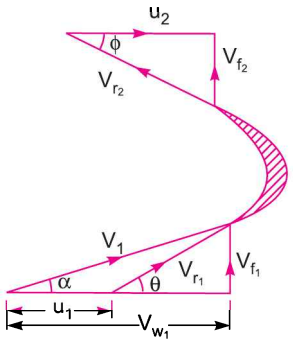

Fig. 18.27

Using the relation, $\eta_o = \dfrac{\text{S.P.}}{\text{W.P.}}$

where $\text{W.P.} = \dfrac{\text{W.P.}}{1000} = \dfrac{\rho \times g \times Q \times H}{1000}$, we get

$$0.84 = \frac{11772}{\dfrac{\rho \times g \times Q \times H}{1000}}$$

$$= \frac{11772 \times 1000}{1000 \times 9.81 \times Q \times 20} \qquad (\because \ \rho = 1000)$$

$$\therefore \quad Q = \frac{11772 \times 1000}{0.84 \times 1000 \times 9.81 \times 20} = 71.428 \text{ m}^3/\text{s}.$$

Using equation (18.25), $Q = \frac{\pi}{4}\left(D_o^2 - D_b^2\right) \times V_{f_1}$

or $$71.428 = \frac{\pi}{4}(3.5^2 - 1.75^2) \times V_{f_1} = \frac{\pi}{4}(12.25 - 3.0625)\ V_{f_1}$$

$$= 7.216\ V_{f_1}$$

$$\therefore \quad V_{f_1} = \frac{71.428}{7.216} = 9.9 \text{ m/s}.$$

From inlet velocity triangle, $\tan \alpha = \frac{V_{f_2}}{V_{w_1}}$

$$\therefore \quad V_{w_1} = \frac{V_{f_1}}{\tan \alpha} = \frac{9.9}{\tan 35^\circ} = \frac{9.9}{.7} = 14.14 \text{ m/s}$$

Using the relation for hydraulic efficiency,

$$\eta_h = \frac{V_{w_1} u_1}{gH} \qquad (\because \ V_{w_2} = 0)$$

$$0.88 = \frac{14.14 \times u_1}{9.81 \times 20}$$

$$\therefore \quad u_1 = \frac{0.88 \times 9.81 \times 20}{14.14} = 12.21 \text{ m/s}.$$

(*i*) Runner vane angles at inlet and outlet at the extreme edge of the runner are given as :

$$\tan \theta = \frac{V_{f_1}}{V_{w_1} - u_1} = \frac{9.9}{(14.14 - 12.21)} = 5.13$$

$$\therefore \quad \theta = \tan^{-1} 5.13 = \mathbf{78.97^\circ} \text{ or } \mathbf{78^\circ\ 58'}. \ \mathbf{Ans.}$$

For Kaplan turbine, $u_1 = u_2 = 12.21$ m/s and $V_{f_1} = V_{f_2} = 9.9$ m/s

$\therefore$ From outlet velocity triangle, $\tan \phi = \frac{V_{f_2}}{u_2} = \frac{9.9}{12.21} = 0.811$

$$\therefore \quad \phi = \tan^{-1}.811 = \mathbf{39.035^\circ} \text{ or } \mathbf{39^\circ\ 2'}. \ \mathbf{Ans.}$$

(*ii*) Speed of turbine is given by $u_1 = u_2 = \frac{\pi D_o N}{60}$

$$12.21 = \frac{\pi \times 3.5 \times N}{60}$$

$$\therefore \quad N = \frac{60 \times 12.21}{\pi \times 3.50} = \mathbf{66.63 \text{ r.p.m.}} \ \mathbf{Ans.}$$

Problem 18.28 *A Kaplan turbine develops 24647.6 kW power at an average head of 39 metres. Assuming a speed ratio of 2, flow ratio of 0.6, diameter of the boss equal to 0.35 times the diameter of the runner and an overall efficiency of 90%, calculate the diameter, speed and specific speed of the turbine.*

Solution. Given :

Shaft power, S.P. = 24647.6 kW

Head, $H = 39$ m

Speed ratio, $u_1\sqrt{2gH} = 2.0$

$\therefore \quad u_1 = 2.0 \times \sqrt{2gH} = 2.0 \times \sqrt{2 \times 9.81 \times 39} = 55.32$ m/s

Flow ratio, $\dfrac{V_{f_1}}{\sqrt{2gH}} = 0.6$

$\therefore \quad V_{f_1} = 0.6 \times \sqrt{2gH} = 0.6 \times \sqrt{2 \times 9.81 \times 39} = 16.59$ m/s

Diameter of boss = 0.35 × Diameter of runner

$\therefore \quad D_b = 0.35 \times D_o$

Overall efficiency, $\eta_o = 90\% = 0.90$

Using the relation, $\eta_o = \dfrac{\text{S.P.}}{\text{W.P.}}$, where W.P. $= \dfrac{\rho \times g \times Q \times H}{1000}$

$\therefore \quad 0.90 = \dfrac{24647.6}{\dfrac{\rho \times g \times Q \times H}{1000}} = \dfrac{24647.6 \times 1000}{1000 \times 9.81 \times Q \times 39}$

$\therefore \quad Q = \dfrac{24647.6 \times 1000}{0.9 \times 1000 \times 9.81 \times 39} = 71.58 \text{ m}^3/\text{s}.$

But from equation (18.25), we have

$$Q = \frac{\pi}{4}\left(D_o^2 - D_b^2\right) \times V_{f_1}$$

$\therefore \quad 71.58 = \dfrac{\pi}{4}\left[D_o^2 - (.35\, D_o)^2\right] \times 16.59 \qquad \left(\because \quad D_b = 0.35\, D_o,\ V_{f_1} = 16.59\right)$

$$= \frac{\pi}{4}\left[D_o^2 - .1225\, D_o^2\right] \times 16.59$$

$$= \frac{\pi}{4} \times .8775\, D_o^2 \times 16.59 = 11.433\, D_o^2$$

(*i*) $\therefore \quad D_o = \sqrt{\dfrac{71.58}{11.433}} =$ **2.5 m. Ans.**

$\therefore \quad D_b = 0.35 \times D_o = 0.35 \times 2.5 =$ **0.875 m. Ans.**

(*ii*) Speed of the turbine is given by $u_1 = \dfrac{\pi D_o N}{60}$

$\therefore \quad 55.32 = \dfrac{\pi \times 2.5 \times N}{60}$

$$\therefore \quad N = \frac{60 \times 55.32}{\pi \times 2.5} = \textbf{422.61 r.p.m. Ans.}$$

(*iii*) Specific speed * is given by $N_s = \frac{N\sqrt{P}}{H^{5/4}}$, where P = Shaft power in kW

$$\therefore \quad N_s = \frac{422.61 \times \sqrt{24647.6}}{(39)^{5/4}} = \frac{422.61 \times 156.99}{97.461} = \textbf{680.76 r.p.m. Ans.}$$

Problem 18.29 *A Kaplan turbine runner is to be designed to develop 9100 kW. The net available head is 5.6 m. If the speed ratio = 2.09, flow ratio = 0.68, overall efficiency = 86% and the diameter of the boss is 1/3 the diameter of the runner. Find the diameter of the runner, its speed and the specific speed of the turbine.*

Solution. Given :

Power, $P = 9100$ kW

Net head, $H = 5.6$ m

Speed ratio $= 2.09$

Flow ratio $= 0.68$

Overall efficiency, $\eta_o = 86\% = 0.86$

Diameter of boss $= \frac{1}{3}$ of diameter of runner

or $$D_b = \frac{1}{3} D_o$$

Now, speed ratio $$= \frac{u_1}{\sqrt{2gH}}$$

$$\therefore \quad u_1 = 2.09 \times \sqrt{2 \times 9.81 \times 5.6} = 21.95 \text{ m/s}$$

Flow ratio $$= \frac{V_{f_1}}{\sqrt{2gH}}$$

$$\therefore \quad V_{f_1} = 0.68 \times \sqrt{2 \times 9.81 \times 5.6} = 7.12 \text{ m/s}$$

The overall efficiency is given by, $\eta_o = \dfrac{P}{\left(\dfrac{\rho \times g.Q.H}{1000}\right)}$

or $$Q = \frac{P \times 1000}{\rho \times g \times H \times \eta_o} = \frac{9100 \times 1000}{1000 \times 9.81 \times 5.6 \times 0.86}$$

$$\left(\because \quad \rho g = 1000 \times 9.81 \text{ N/m}^3\right)$$

$$= 192.5 \text{ m}^3/\text{s}.$$

The discharge through a Kaplan turbine is given by

$$Q = \frac{\pi}{4}[D_o^2 - D_b^2] \times V_{f_1}$$

* For the definition and derivation, please refer to page 920 Arts. 18.11 and 18.11.1.

or $$192.5 = \frac{\pi}{4}\left[D_o^2 - \left(\frac{D_o}{3}\right)^2\right] \times 7.12 \qquad \left(\because\ D_b = \frac{D_o}{3}\right)$$

$$= \frac{\pi}{4}\left[1 - \frac{1}{9}\right] D_o^2 \times 7.12$$

$$\therefore \quad D_o = \sqrt{\frac{4 \times 192.5 \times 9}{\pi \times 8 \times 7.12}} = \mathbf{6.21\ m.\ Ans.}$$

The speed of turbine is given by, $u_1 = \frac{\pi DN}{60}$

$$\therefore \quad N = \frac{60 \times u_1}{\pi \times D} = \frac{60 \times 21.95}{\pi \times 6.21} = \mathbf{67.5\ r.p.m.\ Ans.}$$

The specific speed is given by, $N_s = \frac{N\sqrt{P}}{H^{5/4}} = \frac{67.5 \times \sqrt{9100}}{5.6^{5/4}} = \mathbf{746.\ Ans.}$

Problem 18.30 *The hub diameter of a Kaplan turbine, working under a head of 12 m, is 0.35 times the diameter of the runner. The turbine is running at 100 r.p.m. If the vane angle of the extreme edge of the runner at outlet is 15° and flow ratio is 0.6, find :*

(i) Diameter of the runner, (ii) Diameter of the boss, and

(iii) Discharge through the runner.

The velocity of whirl at outlet is given as zero.

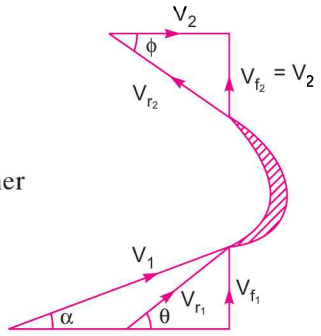

Fig. 18.28

Solution. Given :

Head, $H = 12$ m

Hub diameter, $D_b = 0.35 \times D_o$, where D_o = Dia. of runner

Speed, $N = 100$ r.p.m.

Vane angle at outlet, $\phi = 15°$

Flow ratio $= \frac{V_{f_1}}{\sqrt{2gH}} = 0.6$

$$\therefore \quad V_{f_1} = 0.6 \times \sqrt{2gH} = 0.6 \times \sqrt{2 \times 9.81 \times 12}$$

$$= 9.2 \text{ m/s.}$$

From the outlet velocity triangle, $V_{w_2} = 0$

$$\tan\phi = \frac{V_{f_2}}{u_2} = \frac{V_{f_1}}{u_2} \qquad \left(\because\ V_{f_2} = V_{f_1} = 9.2\right)$$

$$\therefore \quad \tan 15° = \frac{9.2}{u_2}$$

$$\therefore \quad u_2 = \frac{9.2}{\tan 15°} = 34.33 \text{ m/s.}$$

But for Kaplan turbine, $u_1 = u_2 = 34.33$

Now, using the relation, $u_1 = \frac{\pi D_o \times N}{60}$ or $34.33 = \frac{\pi \times D_o \times 100}{60}$

$$D_o = \frac{60 \times 34.33}{\pi \times 100} = \textbf{6.55 m. Ans.}$$

$\therefore$ $D_b = 0.35 \times D_o = 0.35 \times 6.35 = \textbf{2.3 m. Ans.}$

Discharge through turbine is given by equation (18.25) as

$$Q = \frac{\pi}{4}\left[D_o^2 - D_b^2\right] \times V_{f_1} = \frac{\pi}{4}\left[6.55^2 - 2.3^2\right] \times 9.2$$

$$= \frac{\pi}{4}(42.9026 - 5.29) \times 9.2 = \textbf{271.77 m}^3\textbf{/s. Ans.}$$

Problem 18.31 *A Kaplan turbine runner is to be designed to develop 7357.5 kW shaft power. The net available head is 5.50 m. Assume that the speed ratio is 2.09 and flow ratio is 0.68, and the overall efficiency is 60%. The diameter of the boss is* $\frac{1}{3}$*rd of the diameter of the runner. Find the diameter of the runner, its speed and its specific speed.*

Solution. Given :

Shaft power, $P = 7357.5$ kW

Head, $H = 5.50$ m

Speed ratio $= \dfrac{u_1}{\sqrt{2gH}} = 2.09$

$\therefore$ $u_1 = 2.09 \times \sqrt{2 \times 9.81 \times 5.50} = 21.71$ m/s

Flow ratio $= \dfrac{V_{f_1}}{\sqrt{2gH}} = 0.68$

$\therefore$ $V_{f_1} = 2.68 \times \sqrt{2 \times 9.81 \times 5.50} = 7.064$ m/s

Overall efficiency, $\eta_o = 60\% = 0.60$

Diameter of boss, $D_b = \dfrac{1}{3} \times D_o$

Using relation, $\eta_o = \dfrac{\text{Shaft power}}{\text{Water power}} = \dfrac{7357.5}{\dfrac{\rho \times g \times Q \times H}{1000}}$

or $0.60 = \dfrac{7357.5 \times 1000}{\rho \times g \times Q \times H} = \dfrac{7357.5 \times 1000}{1000 \times 9.81 \times Q \times 5.5}$

$\therefore$ $Q = \dfrac{7357.5 \times 1000}{1000 \times 9.81 \times 5.5 \times 0.60} = 227.27$ m^3/s.

Using equation (18.25) for discharge,

$$Q = \frac{\pi}{4}\left(D_o^2 - D_b^2\right) \times V_{f_1}$$

or $$227.27 = \frac{\pi}{4}\left[D_o^2 - \left(\frac{D_o}{3}\right)^2\right] \times 7.064 \qquad \left(\because\ D_b = \frac{D_o}{3}\right)$$

$$= \frac{\pi}{4} \times \frac{8}{9} D_o^2 \times 7.064 = 4.9316\ D_o^2$$

$\therefore$ $$D_o = \sqrt{\frac{227.27}{4.9316}} = \mathbf{6.788\ m.\ Ans.}$$

And $$D_b = \frac{1}{3} \times 6.788 = \mathbf{2.262\ m.\ Ans.}$$

Using the relation, $$u_1 = \frac{\pi D_o \times N}{60}$$

$\therefore$ $$N = \frac{60 \times u_1}{\pi D_o} = \frac{60 \times 21.71}{\pi \times 6.788} = \mathbf{61.08\ r.p.m.\ Ans.}$$

The specific speed (N_s) is given by,

$$N_s = \frac{N\sqrt{P}}{H^{5/4}} = \frac{61.08 \times \sqrt{7357.5}}{5.50^{5/4}} = \mathbf{622\ r.p.m.\ Ans.}$$

Problem 18.32 *In a tidal power plant, a bulb turbine (which is basically an axial flow turbine) operates a 5 MW generator at 150 r.p.m. under a head of 5.5 m. The generator efficiency is 93% and the overall efficiency of the turbine is 88%. The tip diameter of the runner is 4.5 m and hub diameter is 2 m. Assuming hydraulic efficiency of 94% and no exit whirl, determine the runner vane angles at inlet and exit at the mean diameter of the vanes.*

Solution. Given :

Output of generator $= 5$ M* W $= 5 \times 10^6$ W
Speed of turbine, $N = 150$ r.p.m.
Head on turbine, $H = 5.5$ m
Generator efficiency, $\eta_g = 93\%$ or 0.93
Overall efficiency of the turbine, $\eta_o = 88\%$ or 0.88
Tip dia. of runner, $D_o = 4.5$ m
Hub dia. of runner, $D_b = 2$ m
Hydraulic efficiency, $\eta_h = 94\%$ or 0.94

No exit whirl means the velocity of whirl at outlet is zero *i.e.*, $V_{w_2} = 0$. And hence angle $\beta = 90°$ as shown in Fig. 18.29.

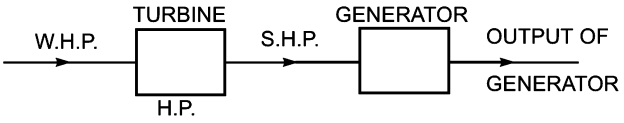

Fig. 18.29

Now, generator efficiency is given by,

$$\eta_g = \frac{\text{Output of generator}}{\text{Input of generator}}$$

$$= \frac{\text{Output of generator}}{\text{Output of turbine}} \quad (\because \text{Output of turbine} = \text{Input of generator})$$

or $$0.93 = \frac{5 \times 10^6}{\text{S.P.}}$$

$\therefore$ $$\text{S.P.} = \frac{5 \times 10^6}{0.93} \text{W} \qquad ...(i)$$

* MW stands for Mega Watt which is equal to 10^6 Watt or 10^6 W.

Now, overall efficiency of turbine is given by, $\eta_o = \dfrac{\text{S.P.}}{\text{W.P.}}$

But W.P. in Watt $= \rho \times Q \times H \times 9.81 = 1000 \times Q \times 5.5 \times 9.81$ W

$\therefore \quad \eta_o = \dfrac{\text{S.P.}}{1000 \times Q \times 5.5 \times 9.81}$

$\therefore \quad \text{S.P.} = \eta_o \times 1000 \times Q \times 5.5 \times 9.81$ ...(*ii*)

Equating the two values of S.P. given by equations (*i*) and (*ii*), we get

$$\frac{5 \times 10^6}{0.93} = 0.88 \times 1000 \times Q \times 5.5 \times 9.81 \qquad (\because \eta_o = 0.88)$$

$$\therefore \quad Q = \frac{5 \times 10^6}{0.93 \times 0.88 \times 1000 \times 5.5 \times 9.81} = 113.23 \text{ m}^3/\text{s}$$

The vane angles are to be calculated at the mean diameter of the runner.

$\therefore$ Mean diameter, $D_m = \dfrac{D_o + D_b}{2} = \dfrac{4.5 + 2.0}{2} = 3.25$ m

Inlet vane velocity corresponding to mean dia. is given by,

$$u_1 = \frac{\pi D_m \times N}{60} = \frac{\pi \times 3.25 \times 150}{60} = 25.52 \text{ m/s}$$

For axial flow turbine, $u_1 = u_2 = 25.52$ m/s and $V_{f_1} = V_{f_2}$

For no whirl velocity at outlet, the hydraulic efficiency is given by,

$$\eta_h = \frac{V_{w_2} \times u_1}{g \times H} \text{ or } 0.94 = \frac{V_{w_1} \times 25.52}{9.81 \times 5.5}$$

$$\therefore \quad V_{w_1} = \frac{0.94 \times 9.81 \times 5.5}{25.52} = 1.987 \text{ m/s}$$

This value of V_{w_1} is less than u_1. Hence, the velocity triangle at inlet will be as shown in Fig. 18.30.

Now, using equation (18.25), we get

$$Q = \frac{\pi}{4}\left(D_o^2 - D_b^2\right) \times V_{f_1}$$

or $$113.23 = \frac{\pi}{4}(4.5^2 - 2^2) \times V_{f_1} = \frac{\pi}{4} \times 16.25 \times V_{f_1}$$

$$\therefore \quad V_{f_1} = \frac{113.23 \times 4}{\pi \times 16.25} = 8.87 \text{ m/s}$$

$$\therefore \quad V_{f_2} = V_{f_1} = 8.87 \text{ m/s.}$$

Let θ = Runner vane angle at inlet and

ϕ = Runner vane angle at outlet.

From inlet velocity triangle,

$$\tan\theta = \frac{V_{f_1}}{(u_1 - V_{w_1})} = \frac{8.87}{25.52 - 1.987}$$

$$= 0.3769$$

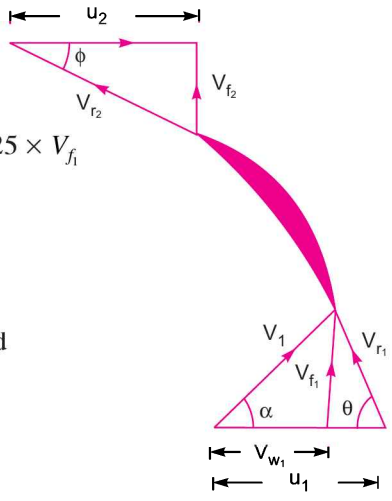

Fig. 18.30

$\therefore \quad \theta = \tan^{-1} 0.3769 = \mathbf{20.65°}$. **Ans.**

Now, from outlet velocity triangle,

$$\tan \phi = \frac{V_{f_2}}{u_2} = \frac{8.87}{25.52} \qquad \left(\because \ V_{f_2} = V_{f_1} \text{ and } u_1 = u_2\right)$$

$$= 0.347$$

$\therefore \quad \phi = \tan^{-1} 0.347 = \mathbf{19.16°}$. **Ans.**

Problem 18.33 *A propeller reaction turbine of runner diameter 4.5 m is running at 40 r.p.m. The guide blade angle at inlet is 145° and runner blade angle at outlet is 25° to the direction of vane. The axial flow area of water through runner is 25 m^2. If the runner blade angle at inlet is radial determine :*

(i) Hydraulic efficiency of the turbine, (ii) Discharge through turbine,

(iii) Power developed by the turbine, and (iv) Specific speed of the turbine.

Solution. Given :

Runner diameter, $D_o = 4.5$ m

Speed, $N = 40$ r.p.m.

Guide blade angle, $\alpha = 145°$

Runner blade angle at outlet, $\phi = 25°$

Flow area, $a = 25$ m^2

Runner blade angle at inlet is radial

$\therefore \quad \theta = 90°$, $V_{r_1} = V_{f_1}$ and $u_1 = V_{w_1}$

For Kaplan turbine, the discharge is given by the product of area of flow and velocity of flow.

As area of flow is constant and hence $V_{f_1} = V_{f_2}$ ($\because$ Q = Area of flow $\times$ V_{f_1} = Area of flow $\times$ V_{f_2})

The tangential speed of turbine at inlet,

$$u_1 = \frac{\pi D_o N}{60} = \frac{\pi \times 4.5 \times 40}{60}$$

$$= 9.42 \text{ m/s}$$

Also $u_2 = u_1 = 9.42$ m/s.

From inlet velocity triangle,

$$\tan (180° - \alpha) = \frac{V_{f_1}}{u_1}$$

or $$\tan (180° - 145°) = \tan 35° = \frac{V_{f_1}}{u_1}$$

$\therefore \quad V_{f_1} = u_1 \tan 35° = 9.42 \tan 35° = 6.59$

Also $V_{w_1} = u_1 = 9.42$ m/s.

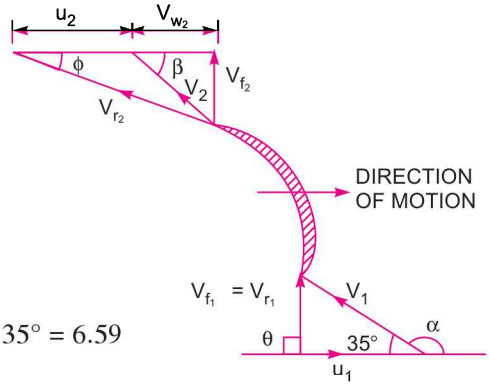

Fig. 18.31

From outlet velocity triangle,

$$\tan \phi = \frac{V_{f_2}}{u_2 + V_{w_2}} \qquad \text{(where } V_{f_2} = V_{f_1} = 6.59 \text{ and } u_2 = u_1 = 9.42\text{)}$$

$\therefore \quad \tan 25° = \dfrac{6.59}{9.42 + V_{w_2}}$

$$\therefore \quad V_{w_2} + 9.42 = \frac{6.59}{\tan 25^\circ} = 14.13$$

$$\therefore \quad V_{w_2} = 14.13 - 9.42 = 4.71 \text{ m/s}$$

$$\therefore \quad V_2 = \sqrt{V_{f_2}^2 + V_{w_2}^2} = \sqrt{6.59^2 + 4.71^2} = \sqrt{43.43 + 22.18} = 8.1 \text{ m/s.}$$

Using equation (18.24),

$$H - \frac{V_2^2}{2g} = \frac{1}{g}\left[V_{w_1}u_1 - V_{w_2}u_2\right].$$

Here –ve sign is taken as the absolute velocity at inlet and outlet (*i.e.*, V_1 and V_2) are in the same direction and hence change of velocity will be with a –ve sign

$$\therefore \quad H - \frac{8.1^2}{2 \times 9.81} = \frac{1}{9.81}\,[9.42 \times 9.42 - 4.71 \times 9.42]$$

$$H - 3.344 = \frac{1}{9.81}\,[88.736 - 44.368] = 4.522 \text{ m}$$

$$\therefore \quad H = 4.522 + 3.344 = 7.866 \text{ m.}$$

(*i*) Hydraulic efficiency is given by equation (18.20*A*) as

$$\eta_h = \frac{V_{w_1}u_1 - V_{w_2}u_2}{g \times H}$$

$$= \frac{(9.42 \times 9.42 - 4.71 \times 9.42)}{9.81 \times 7.866} = 0.575 = \mathbf{57.5\%.\ Ans.}$$

(*ii*) Discharge through turbine is given by,

$$Q = \text{Area of flow} \times \text{Velocity of flow}$$

$$= 25 \times V_{f_1} = 25 \times 6.59 = \mathbf{164.75\ m^3/s.\ Ans.}$$

(*iii*) Power developed by turbine $= \dfrac{\text{Work done per second}}{1000}$

$$= \frac{1}{g}\frac{\left[V_{w_1}u_1 - V_{w_2}u_2\right]}{1000} \times \text{Weight of water}$$

$$= \frac{1}{9.81}\left[\frac{9.42 \times 9.42 - 4.71 \times 9.42}{1000}\right] \times \rho \times g \times Q$$

$$= \frac{1}{9.81}\left[\frac{9.42 \times 9.42 - 4.71 \times 9.42}{1000}\right] \times 1000 \times 9.81 \times 164.75$$

$$= \mathbf{6867\ kW.\ Ans.}$$

(*iv*) Specific speed is given by the relation,

$$N_s = \frac{N\sqrt{P}}{H^{5/4}} = \frac{N\sqrt{6867}}{7.866^{5/4}} = \frac{40 \times \sqrt{6867}}{7.866^{5/4}}$$

$$= \frac{40 \times 82.867}{13.173} = \mathbf{251.62\ r.p.m.\ Ans.}$$

▶ 18.10 DRAFT-TUBE

The draft-tube is a pipe of gradually increasing area which connects the outlet of the runner to the tail race. It is used for discharging water from the exit of the turbine to the tail race. This pipe of gradually increasing area is called a draft-tube. One end of the draft-tube is connected to the outlet of the runnner while the other end is sub-merged below the level of water in the tail race. The draft-tube, in addition to serve a passage for water discharge, has the following two purposes also :

1. It permits a negative head to be established at the outlet of the runner and thereby increase the net head on the turbine. The turbine may be placed above the tail race without any loss of net head and hence turbine may be inspected properly.

2. It converts a large proportion of the kinetic energy $(V_2^2/2g)$ rejected at the outlet of the turbine into useful pressure energy. Without the draft tube, the kinetic energy rejected at the outlet of the turbine will go waste to the tail race.

Hence by using draft-tube, the net head on the turbine increases. The turbine develops more power and also the efficiency of the turbine increases.

If a reaction turbine is not fitted with a draft-tube, the pressure at the outlet of the runner will be equal to atmospheric pressure. The water from the outlet of the runner will discharge freely into the tail race. The net head on the turbine will be less than that of a reaction turbine fitted with a draft-tube. Also without a draft-tube, the kinetic energy $\left(\frac{V_2^2}{2g}\right)$ rejected at the outlet of the runner will go waste to the tail race.

18.10.1 Types of Draft-Tubes. The following are the important types of draft-tubes which are commonly used :

1. Conical draft-tubes,
2. Simple elbow tubes,
3. Moody spreading tubes, and
4. Elbow draft-tubes with circular inlet and rectangular outlet.

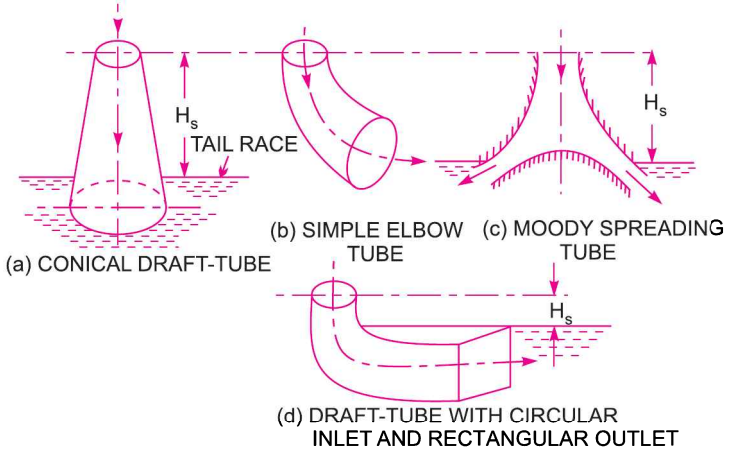

Fig. 18.32 *Types of draft-tubes.*

These different types of draft-tubes are shown in Fig. 18.32. The conical draft-tubes and Moody spreading draft-tubes are most efficient while simple elbow tubes and elbow draft-tubes with circular inlet and rectangular outlet require less space as compared to other draft-tubes.

18.10.2 Draft-Tube Theory. Consider a capital draft-tube as shown in Fig. 18.33.

Let H_s = Vertical height of draft-tube above the tail race,

y = Distance of bottom of draft-tube from tail race.

Applying Bernoulli's equation to inlet (section 1-1) and outlet (section 2-2) of the draft-tube and taking section 2-2 as the datum line,we get

$$\frac{p_1}{\rho g}+\frac{V_1^2}{2g}+(H_s+y)=\frac{p_2}{\rho g}+\frac{V_2^2}{2g}+0+h_f \qquad ...(i)$$

where h_f = loss of energy between sections 1-1 and 2-2.

But $\frac{p_2}{\rho g}$ = Atmospheric pressure head + y

$$=\frac{p_a}{\rho g}+y.$$

Substituting this value of $\frac{p_2}{\rho g}$ in equation (i), we get

$$\frac{p_1}{\rho g}+\frac{V_1^2}{2g}+(H_s+y)=\frac{p_a}{\rho g}+y+\frac{V_2^2}{2g}+h_f$$

or $$\frac{p_1}{\rho g}+\frac{V_1^2}{2g}+H_s=\frac{p_a}{\rho g}+\frac{V_2^2}{2g}+h_f$$

$$\therefore \quad \frac{p_1}{\rho g}=\frac{p_a}{\rho g}+\frac{V_2^2}{2g}+h_f-\frac{V_1^2}{2g}-H_s$$

$$=\frac{p_a}{\rho g}-H_s-\left(\frac{V_1^2}{2g}-\frac{V_2^2}{2g}-h_f\right) \qquad ...(18.26)$$

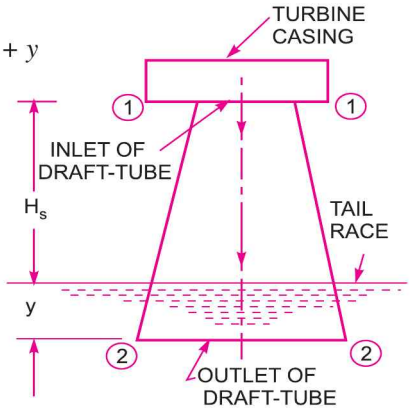

Fig. 18.33 *Draft-tube theory.*

In equation (18.26), $\frac{p_1}{\rho g}$ is less than atmospheric pressure.

18.10.3 Efficiency of Draft-Tube. The efficiency of a draft-tube is defined as the ratio of actual conversion of kinetic head into pressure head in the draft-tube to the kinetic head at the inlet of the draft-tube. Mathematically, it is written as

$$\eta_d=\frac{\text{Actual conversion of kinetic head into pressure head}}{\text{Kinetic head at the inlet of draft-tube}}$$

Let V_1 = Velocity of water at inlet of draft-tube,

V_2 = Velocity of water at outlet of draft-tube, and

h_f = Loss of head in the draft-tube.

Theoretical conversion of kinetic head into pressure head in draft-tube = $\left(\frac{V_1^2}{2g}-\frac{V_2^2}{2g}\right)$.

Actual conversion of kinetic head into pressure head = $\left(\frac{V_1^2}{2g}-\frac{V_2^2}{2g}\right)-h_f$

$$\therefore \qquad \eta_d = \frac{\left(\frac{V_1^2}{2g} - \frac{V_2^2}{2g}\right) - h_f}{\left(\frac{V_1^2}{2g}\right)} \qquad ...(18.27)$$

Problem 18.33 (A) *A water turbine has a velocity of 6 m/s at the entrance to the draft-tube and a velocity of 1.2 m/s at the exit. For friction losses of 0.1 m and a tail water 5 m below the entrance to the draft-tube, find the pressure head at the entrance.*

Solution. Given :

Velocity at inlet, $V_1 = 6$ m/s

Velocity at outlet, $V_2 = 1.2$ m/s

Friction loss, $h_f = 0.1$ m

Vertical height between tail race and inlet of draft-tube = 5 m

Let y = Vertical height between tail race and outlet of draft-tube.

Applying Bernoulli's equation at the inlet and outlet of draft-tube and taking reference line passing through section (2-2), we get

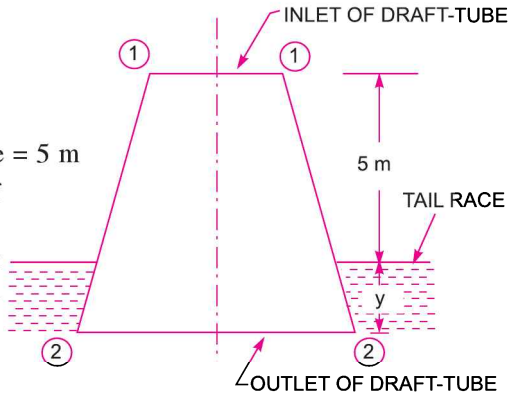

Fig. 18.33 (*a*)

$$\frac{p_1}{\rho g} + \frac{V_1^2}{2g} + Z_1 = \frac{p_2}{\rho g} + \frac{V_2^2}{2g} + Z_2 + h_f$$

where $Z_1 = (5 + y)$; $V_1 = 6$ m/s ; $V_2 = 1.2$ m/s,

$h_f = 0.1$

$$\frac{p_2}{\rho g} = \text{Atmospheric pressure head} + y = \frac{p_a}{\rho g} + y$$

$$Z_2 = 0$$

Substituting the values, we get

$$\frac{p_1}{\rho g} + \frac{6^2}{2 \times 9.81} + (5 + y) = \left(\frac{p_a}{\rho g} + y\right) + \frac{1.2^2}{2 \times 9.81} + 0 + 0.1$$

or $$\frac{p_1}{\rho g} + 1.835 + 5 + y = \frac{p_a}{\rho g} + y + 0.0734 + 0.1$$

or $$\frac{p_1}{\rho g} + 6.835 = \frac{p_a}{\rho g} + 0.1734 \qquad ...(i)$$

If $\frac{p_a}{\rho g}$ (*i.e.*, atmospheric pressure head) is taken zero, then we will get $\frac{p_1}{\rho g}$ as vacuum pressure head at inlet of draft-tube.

But if $\frac{p_a}{\rho g} = 10.3$ m of water, then we will get $\frac{p_1}{\rho g}$ as absolute pressure head at inlet of draft-tube.

Taking $\frac{p_a}{\rho g} = 0$ and substituting this value in equation (*i*), we get

$$\frac{p_1}{\rho g} + 6.835 = 0 + 0.1734$$

$$\therefore \quad \frac{p_1}{\rho g} = -6.835 + 0.1734 = \mathbf{-6.6616\ m.\ Ans.}$$

Negative sign means vacuum pressure head.

Problem 18.34 *A conical draft-tube having diameter at the top as 2.0 m and pressure head at 7 m of water (vacuum), discharges water at the outlet with a velocity of 1.2 m/s at the rate of 25 m^3/s. If atmospheric pressure head is 10.3 m of water and losses between the inlet and outlet of the draft-tubes are negligible, find the length of draft-tube immersed in water. Total length of tube is 5 m.*

Solution. Given :

Diameter at top, $D_1 = 2.0$ m

Pressure head, $\frac{p_1}{\rho g} = 7$ m (Vacuum)

$= 10.3 - 7.0 = 3.3$ m (abs.)

Velocity at outlet, $V_2 = 1.2$ m/s

Discharge, $Q = 25\ m^3/s$

Loss of energy, h_f = Negligible

Let the length of the tube immersed in water = y m.

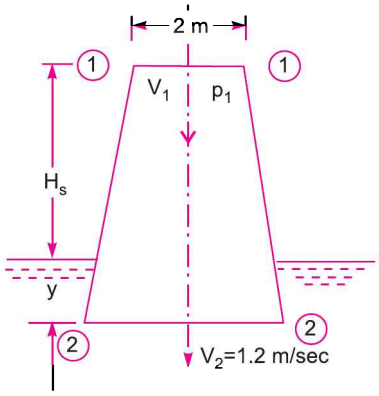

Fig. 18.34

Total length of the tube = 5 m

The velocity at inlet, $V_1 = \frac{\text{Discharge}}{\text{Area at inlet}}$

$$= \frac{Q}{\frac{\pi}{4}D_1^2} = \frac{25}{\frac{\pi}{4}(2.0)^2} = 7.957 \text{ m/s.}$$

Using equation (18.26), we have

$$\frac{p_1}{\rho g} = \frac{p_a}{\rho g} - H_s - \left(\frac{V_1^2}{2g} - \frac{V_2^2}{2g} - h_f\right)$$

$$3.30 = 10.3 - H_s - \left(\frac{7.957^2}{2\times 9.81} - \frac{1.2^2}{2\times 9.81} - 0\right)$$

$$\left(\because \ h_f = 0 \text{ and } \frac{p_a}{\rho g} = 10.3\right)$$

$$= 10.3 - H_s - (3.227 - .0734)$$

or $3.3 = 10.3 - H_s - 3.1536$

$\therefore \quad H_s = 10.3 - 3.1536 - 3.3 = 3.8464$ m

$\therefore \quad y$ = Total length $- H_s = 5 - 3.8464 =$ **1.1536 m. Ans.**

Problem 18.35 *A conical draft-tube having inlet and outlet diameters 1 m and 1.5 m discharges water at outlet with a velocity of 2.5 m/s. The total length of the draft-tube is 6 m and 1.20 m of the length of draft-tube is immersed in water . If the atmospheric pressure head is 10.3 m of water and loss of head due to friction in the draft-tube is equal to 0.2 × velocity head at outlet of the tube, find :*

(i) Pressure head at inlet, and (ii) Efficiency of the draft-tube.

Solution. Given :

Diameter at inlet, $D_1 = 1.0$ m

Diameter at outlet $D_2 = 1.5$ m

Velocity at outlet, $V_2 = 2.5$ m/s

Total length of tube, $H_s + y = 6.0$ m

Length of tube in water, $y = 1.20$ m

$\therefore$ $H_s = 6.0 - 1.20 = 4.80$ m

Atmospheric pressure head, $\frac{p_a}{\rho g} = 10.3$ m

Loss of head due to friction, $h_f = 0.2 \times$ Velocity head at outlet

$$= 0.2 \times \frac{V_2^2}{2g}$$

Discharge through tube, $Q = A_2 V_2 = \frac{\pi}{4} D_2^2 \times 2.5 = \frac{\pi}{4} (1.5)^2 \times 2.5 = 4.4178 \text{ m}^3/\text{s}$

Velocity at inlet, $V_1 = \frac{Q}{A_1} = \frac{4.4178}{\frac{\pi}{4} \times 1^2} = 5.625$ m/s

(*i*) *Pressure head at inlet* $\left(\frac{p_1}{\rho g}\right)$.

Using equation (18.26), $\frac{p_1}{\rho g} = \frac{p_a}{\rho g} - H_s - \left(\frac{V_1^2}{2g} - \frac{V_2^2}{2g} - h_f\right)$

$$= 10.3 - 4.8 - \left(\frac{5.625^2}{2 \times 9.81} - \frac{2.5^2}{2 \times 9.81} - 0.2 \times \frac{V_2^2}{2g}\right)$$

$$= 10.3 - 4.8 - \left(1.6126 - .3185 - \frac{0.2 \times 2.5^2}{2 \times 9.81}\right)$$

$= 10.3 - 4.8 - (1.6126 - .3185 - .0637) = 5.5 - (1.2304) = 4.269$

$\simeq$ **4.27 m (abs.) Ans.**

(*ii*) *Efficiency of Draft-tube* (η_d)

Using equation (18.27), $\eta_d = \frac{\left(\frac{V_1^2}{2g} - \frac{V_2^2}{2g}\right) - h_f}{\frac{V_1^2}{2g}} = \frac{\frac{V_1^2}{2g} - \frac{V_2^2}{2g} - \frac{0.2\, V_2^2}{2g}}{\frac{V_1^2}{2g}}$

$$= \frac{V_1^2 - 1.2\, V_2^2}{V_1^2} = 1 - 1.2 \left(\frac{V_2}{V_1}\right)^2 = 1 - 1.2 \left(\frac{2.5}{5.625}\right)^2 = 1 - 0.237$$

$=$ **0.763** or **76.3%. Ans.**

▶ 18.11 SPECIFIC SPEED

It is defined as the speed of a turbine which is identical in shape, geometrical dimensions, blade angles, gate opening etc., with the actual turbine but of such a size that it will develop unit power when working under unit head. It is denoted by the symbol N_s. The specific speed is used in comparing the different types of turbines as every type of turbine has different specific speed.

In M.K.S. units, unit power is taken as one horse power and unit head as one metre. But in S.I. units, unit power is taken as one kilowatt and unit head as one metre.

18.11.1 Derivation of the Specific Speed. The overall efficiency (η_o) of any turbine is given by,

$$\eta_o = \frac{\text{Shaft power}}{\text{Water power}} = \frac{\text{Power developed}}{\frac{\rho \times g \times Q \times H}{1000}} = \frac{P}{\frac{\rho \times g \times Q \times H}{1000}} \quad ...(i)$$

where H = Head under which the turbine is working,

Q = Discharge through turbine,

P = Power developed or shaft power.

From equation (i), $$P = \eta_o \times \frac{\rho \times g \times Q \times H}{1000}$$

$$\propto Q \times H \text{ (as } \eta_o \text{ and } \rho \text{ are constant)} \quad ...(ii)$$

Now let D = Diameter of actual turbine,

N = Speed of actual turbine,

u = Tangential velocity of the turbine,

N_s = Specific speed of the turbine,

V = Absolute velocity of water.

The absolute velocity, tangential velocity and head on the turbine are related as,

$$u \propto V, \text{ where } V \propto \sqrt{H}$$

$$\propto \sqrt{H} \quad ...(iii)$$

But the tangential velocity u is given by

$$u = \frac{\pi DN}{60}$$

$$\propto DN \quad ...(iv)$$

$\therefore$ From equations (iii) and (iv), we have

$$\sqrt{H} \propto DN \text{ or } D \propto \frac{\sqrt{H}}{N} \quad ...(v)$$

The discharge through turbine is given by

$$Q = \text{Area} \times \text{Velocity}$$

But $$\text{Area} \propto B \times D \quad \text{(where } B = \text{Width)}$$

$$\propto D^2 \quad (\because \ B \propto D)$$

And $$\text{Velocity} \propto \sqrt{H}$$

$\therefore$ $$Q \propto D^2 \times \sqrt{H}$$

$$\propto \left(\frac{\sqrt{H}}{N}\right)^2 \times \sqrt{H} \qquad \left(\because \text{ From equation } (v),\ D \propto \frac{\sqrt{H}}{N}\right)$$

$$\propto \frac{H}{N^2} \times \sqrt{H} \propto \frac{H^{3/2}}{N^2} \qquad ...(vi)$$

Substituting the value of Q in equation (ii), we get

$$P \propto \frac{H^{3/2}}{N^2} \times H \propto \frac{H^{5/2}}{N^2}$$

$$\therefore \qquad P = K\,\frac{H^{5/2}}{N^2}, \text{ where } K = \text{Constant of proportionality.}$$

If $P = 1$, $H = 1$, the speed N = Specific speed N_s. Substituting these values in the above equation, we get

$$1 = \frac{K \times 1^{5/2}}{N_s^2} \qquad \text{or} \qquad N_s^2 = \text{K}$$

$$\therefore \qquad P = N_s^2\,\frac{H^{5/2}}{N^2} \qquad \text{or} \qquad N_s^2 = \frac{N^2 P}{H^{5/2}}$$

$$\therefore \qquad N_s = \sqrt{\frac{N^2 P}{H^{5/2}}} = \frac{N\sqrt{P}}{H^{5/4}} \qquad ...(18.28)$$

In equation (18.28), if P is taken in metric horse power the specific speed is obtained in M.K.S. units. But if P is taken in kilowatts, the specific speed is obtained in S.I. units.

18.11.2 Significance of Specific Speed. Specific speed plays an important role for selecting the type of the turbine. Also the performance of a turbine can be predicted by knowing the specific speed of the turbine. The type of turbine for different specific speed is given in Table 18.1 as :

Table 18.1

S. No.	*Specific speed*		*Types of turbine*
	(M.K.S.)	*(S.I.)*	
1.	10 to 35	8.5 to 30	Pelton wheel with single jet
2.	35 to 60	30 to 51	Pelton wheel with two or more jets
3.	60 to 300	51 to 225	Francis turbine
4.	300 to 1000	255 to 860	Kaplan or Propeller turbine

Problem 18.36 *A turbine develops 7225 kW power under a head of 25 metres at 135 r.p.m. Calculate the specific speed of the turbine and state the type of the turbine.*

Solution. Given :

Power developed, $P = 7225$ kW

Head, $H = 25$ m

Speed, $N = 135$ r.p.m.

Specific speed of the turbine (N_s)

Using equation (18.28),

$$N_s = \frac{N\sqrt{P}}{H^{5/4}} = \frac{135 \times \sqrt{7225}}{25^{5/4}} = \mathbf{205.28.\ Ans.}$$

From Table 18.1, for specific speeds (S.I.) between 51 and 255 the type of turbine is Francis. As the specific speed 205.28 lies in this range and hence type of turbine is Francis. **Ans.**

Problem 18.37 *A turbine is to operate under a head of 25 m at 200 r.p.m. The discharge is 9 cumec. If the efficiency is 90%, determine :*

(i) Specific speed of the machine, (ii) Power generated, and

(iii) Type of turbine.

Solution. Given :

Head, $H = 25$ m

Speed, $N = 200$ r.p.m.

Discharge, $Q = 9$ cumec $= 9\ m^3/s$

Efficiency, $\eta_o = 90\% = 0.90$ (Take the efficiency as overall η)

Now using relation, $$\eta_o = \frac{\text{Power developed}}{\text{Water power}} = \frac{P}{\frac{\rho \times g \times Q \times H}{1000}}$$

$\therefore$ $$P = \eta_o \times \frac{\rho \times g \times Q \times H}{1000}$$

$$= \frac{0.90 \times 9.81 \times 1000 \times 9 \times 25}{1000} = 1986.5 \text{ kW}$$

(*i*) *Specific speed of the machine* (N_s)

Using equation (18.28), $$N_s = \frac{N\sqrt{P}}{H^{5/4}} = \frac{200 \times \sqrt{1986.5}}{25^{5/4}} = \mathbf{159.46\ r.p.m.\ Ans.}$$

(*ii*) *Power generated*

$P =$ **1986.5 kW. Ans.**

(*iii*) As the specific speed lies between 51 and 255, the turbine is a Francis turbine. **Ans.**

Problem 18.38 *A turbine develops 9000 kW when running at a speed of 140 r.p.m. and under a head of 30 m. Determine the specific speed of the turbine.*

Solution. Given :

Power developed, $P = 9000$ kW

Head, $H = 30$ m

Speed , $N = 140$ r.p.m.

The specific speed is given by equation (18.28) as

$$N_s = \frac{N\sqrt{P}}{H^{5/4}} = \frac{140 \times \sqrt{9000}}{30^{5/4}} = \frac{13281.56}{70.21}$$

$$= \mathbf{189.167\ (S.I.\ units).\ Ans.}$$

Problem 18.39 *A Pelton wheel develops 8000 kW under a net head of 130 m at a speed of 200 r.p.m. Assuming the co-efficient of velocity for the nozzle 0.98, hydraulic efficiency 87%, speed ratio 0.46 and jet diameter to wheel diameter ratio $\frac{1}{9}$, determine :*

(i) the discharge required, (ii) the diameter of the wheel,

(iii) the diameter and number of jets required, and (iv) the specific speed.

Mechanical efficiency is 75%.

Solution. Given :

Power developed, $P = 8000$ kW

Net head, $H = 130$ m

Speed, $N = 200$ r.p.m.

Co-efficient of velocity, $C_v = 0.98$

Hydraulic efficiency, $\eta_h = 87\% = 0.87$

Speed ratio, $\dfrac{u_1}{\sqrt{2gH}} = 0.46$

$\therefore \quad u_1 = 0.46 \times \sqrt{2gH} = 0.46 \times \sqrt{2 \times 9.81 \times 130} = 23.23$ m/s.

Jet diameter to wheel diameter $= \dfrac{d}{D} = \dfrac{1}{9}$

Mechanical efficiency, $\eta_m = 75\% = 0.75$

Overall efficiency is given by equation (18.6) as

$$\eta_o = \eta_h \times \eta_m = 0.87 \times 0.75 = 0.6525$$

Also $\eta_o = \dfrac{\text{Power developed}}{\text{Water power}} = \dfrac{8000}{\text{W.P. in kW}}$ or $0.6525 = \dfrac{8000}{\text{W. P. in kW}}$

$\therefore$ W.P. in kW $= \dfrac{8000}{0.6525} = 12260.536$ kW

But W.P. in kW $= \dfrac{\rho \times g \times Q \times H}{1000}$

$= \dfrac{1000 \times 9.81 \times Q \times H}{1000}$ ($\because$ ρg in S.I. $= 1000 \times 9.81$)

$= Q \times H \times 9.81 = Q \times 130 \times 9.81$

$\therefore \quad 12260.536 = Q \times 130 \times 9.81$

$\therefore \quad Q = \dfrac{12260.536}{130 \times 9.81} =$ **9.614 m^3/s. Ans.**

(*i*) *Discharge required*

$Q =$ **9.614 m^3/s. Ans.**

(*ii*) *Diameter of wheel (D)*

Using the relation, $u_1 = \dfrac{\pi DN}{60}$

$\therefore \quad D = \dfrac{60 \times u_1}{\pi \times N} = \dfrac{60 \times 23.23}{\pi \times 200} =$ **2.218 m. Ans.**

(*iii*) *Diameter of jet (d) and number of jets required*

$$\frac{d}{D} = \frac{1}{9}$$

$\therefore \quad d = \dfrac{D}{9} = \dfrac{2.218}{9} = 0.2464$ m = **246.4 mm. Ans.**

$\therefore$ Area of jet, $a = \dfrac{\pi}{4} d^2 = \dfrac{\pi}{4}(.2464)^2 = .04768$ m^2.

Velocity of jet is given by, $V_1 = C_v\sqrt{2gH} = 0.98\sqrt{2\times 9.81\times 130} = 49.49$ m/s

$\therefore$ Discharge through one jet = Area of jet × Velocity of jet = $a \times V_1$

$= .04768 \times 49.49 = 2.359$ m^3/s

$\therefore$ Number of jets $= \dfrac{\text{Total discharge}}{\text{Discharge through one jet}}$

$= \dfrac{Q}{2.359} = \dfrac{9.614}{2.359} = 4.07$ say **4.0. Ans.**

(*iv*) *Specific speed* is given by equation (18.28) as

N_s (S.I. units) $= \dfrac{N\sqrt{P}}{H^{5/4}} = \dfrac{200\times\sqrt{8000}}{130^{5/4}} = \dfrac{17888.54}{438.96} =$ **40.75. Ans.**

Problem 18.40 *A Pelton turbine develops 3000 kW under a head of 300 m. The overall efficiency of the turbine is 83%. If speed ratio = 0.46, C_v = 0.98 and specific speed is 16.5, then find :*

(i) Diameter of the turbine, and (ii) Diameter of the jet.

Solution. Given :

Power, $P = 3000$ kW

Net head, $H = 300$ m

Overall efficiency, $\eta_o = 83\%$ or 0.83

Speed ratio $= 0.46$

Value of C_v, $= 0.98$

Specific speed*, $N_s = 16.5$

Using equation, $N_s = \dfrac{N\sqrt{P}}{H^{5/4}}$ or $N = \dfrac{N_s\, H^{5/4}}{\sqrt{P}} = \dfrac{16.5\times 300^{5/4}}{\sqrt{3000}} = 375$ r.p.m.

The velocity (V) at the outlet of nozzle is given by,

$V = C_v\sqrt{2\times g\times H} = 0.98\sqrt{2\times 9.81\times 300} = 75.1$ m/s

Now speed ratio $= \dfrac{u}{\sqrt{2gH}}$ or u = Speed ratio × $\sqrt{2gH}$

$= 0.46\times\sqrt{2\times 9.81\times 300} = 34.95$ m/s.

(*i*) *Diameter of the turbine (D)*

Using, $u = \dfrac{\pi DN}{60}$ or $D = \dfrac{60\times u}{\pi\times N} = \dfrac{60\times 34.95}{\pi\times 375} =$ **1.78 m. Ans.**

(*ii*) *Diameter of the jet (d)*

Let Q = Discharge through turbine in m^3/s

Using the relation, $\eta_o = \dfrac{P}{\left(\dfrac{\rho\times g\times Q\times H}{1000}\right)}$, where $\rho\times g = 1000\times 9.81$ N/m^3 for water

$\therefore$ $0.83 = \dfrac{3000}{\left(\dfrac{1000\times 9.81\times Q\times 300}{1000}\right)}$

* Specific speed is the speed of the turbine working under a unit head and develops one kilowatt power.

$$\therefore \quad Q = \frac{3000}{9.81 \times 300 \times 0.83} = 1.23 \text{ m}^3/\text{s}$$

But discharge through a Pelton turbine is given by,

$$Q = \text{Area of jet} \times \text{Velocity}$$

or $$1.23 = \frac{\pi}{4} d^2 \times 75.1$$

$$\therefore \quad d = \sqrt{\frac{4 \times 1.23}{\pi \times 75.1}} = 0.142 \text{ m} = \textbf{142 mm. Ans.}$$

Problem 18.41 *Water under a head of 300 m is available for a hydel-plant situated at a distance of 2.35 km from the source. The frictional losses of energy for transporting water is equivalent to 26 (J/N). A number of Pelton wheels are to be installed generating a total output of 18 MW. Determine the number of units to be installed, diameter of Pelton wheel and the jet diameter when the following are available : Wheel speed 650 r.p.m.; ratio of bucket to jet speed 0.46 ; specific speed not to exceed 30 (m, kW, r.p.m.) ; C_v and C_d for the nozzle 0.97 and 0.94 respectively and the overall efficiency of the wheel 87%.*

Solution. Given :

Total head = 300 m

Length = 2.35 km = 2350 m

Frictional losses = 26 (J/N) = 26 (Nm/N) (as J = Nm) = 26 m

$\therefore$ Net head, $H = 300 - 26 = 274$ m

Total output = 18 MW = 18×10^3 kW

$N = 650$ r.p.m.

Ratio of bucket to jet speed = 0.46

$C_v = 0.97$, $C_d = 0.94$

$\eta_o = 87\% = 0.87$

and $N_s = 30$, where H is in m, P in kW and N in r.p.m.

Find : (*i*) Number of units to be installed

(*ii*) Dia. of Pelton wheel (D)

(*iii*) Dia. of jet of water (d)

(*i*) *Number of units to be installed*

Let P = Power output of each unit in kW

Using equation (18.28) as $N_s = \frac{N\sqrt{P}}{H^{5/4}}$ or $30 = \frac{650 \times \sqrt{P}}{274^{5/4}}$ or $\sqrt{P} = \frac{30 \times 274^{5/4}}{650}$

Squaring both sides, we get $P = \frac{30^2 \times 274^{5/2}}{650^2} = 2647.2$ kW

$\therefore$ No. of units $= \frac{\text{Total output in kW}}{\text{Output of one unit in kW}}$

$$= \frac{18 \times 10^3}{2647.2} = 6.799 \simeq \textbf{7 units. Ans.}$$

(*ii*) *Dia. of Pelton wheel (D)*

Velocity of jet is given by, $V_1 = C_v \times \sqrt{2gH}$

$= 0.97 \times \sqrt{2 \times 9.81 \times 274} = 71.12$ (m/s)

But ratio of bucket to jet speed $= 0.46$*

or $$\frac{\text{Speed of bucket}}{\text{Speed of jet}} = 0.46 \text{ or } \frac{u_1}{V_1} = 0.46$$

$$\therefore \quad u_1 = 0.46 \times V_1 = 0.46 \times 71.12 = 32.715 \text{ m/s.}$$

But $$u_1 = \frac{\pi DN}{60}$$

$$\therefore \quad 32.715 = \frac{\pi \times D \times 650}{60} \text{ or } \frac{32.715 \times 60}{\pi \times 650} = D \text{ or } 0.945 \text{ m} = D$$

$\therefore$ Dia. of Pelton wheel $=$ **0.945. Ans.**

(*iii*) *Dia. of jet* (*d*)

We know $$\eta_o = \frac{\text{Total power output}}{\text{Total water power in kW}}$$

or $$0.87 = \frac{18 \times 10^3}{\text{Total water power in kW}}$$

$\therefore$ Total water power in kW $= \dfrac{18 \times 10^3}{0.87} = 20.689 \times 10^3$ kW

$\therefore$ Water power in kW per unit $= \dfrac{\text{Total water power}}{\text{No. of units}} = \dfrac{20.689 \times 10^3}{7} = 2.955 \times 10^3$ kW

But water power in kW per unit is given by equation (18.3 *A*) as,

Water power $$= \frac{\rho \times g \times Q \times H}{1000} \text{ kW}$$

$$\therefore \quad 2.955 \times 10^3 = \frac{\rho \times g \times Q \times H}{1000} = \frac{(1000 \times 9.81) \times Q \times H}{1000}$$

$(\because \rho \times g = 1000 \times 9.81)$

$$= 9.81 \times Q \times 274$$

$$\therefore \quad Q = \frac{2.955 \times 10^3}{9.81 \times 274} = 1.099 \text{ m}^3\text{/s}$$

But discharge (Q) through one unit is also given by

$$Q = C_d \times \frac{\pi}{4} d^2 \times \sqrt{2gH}$$

---

* It is not speed ratio. It is the ratio of bucket speed to jet speed *i.e.*, ratio of u_1 and V_1. Speed ratio is $u_1\sqrt{2gH}$.

or $$1.099 = 0.94 \times \frac{\pi}{4} d^2 \times \sqrt{2 \times 9.81 \times 274}$$

or $$d^2 = \frac{1.099 \times 4}{0.94 \times \pi \times \sqrt{2 \times 9.81 \times 274}} = 0.0203 \text{ m}$$

$\therefore$ $$d = \sqrt{0.0203} = 0.1424 \text{ m} = \mathbf{142.4 \text{ mm. Ans.}}$$

▶ 18.12 UNIT QUANTITIES

In order to predict the behaviour of a turbine working under varying conditions of head, speed, output and gate opening, the results are expressed in terms of quantities which may be obtained when the head on the turbine is reduced to unity. The conditions of the turbine under unit head are such that the efficiency of the turbine remains unaffected. The following are the three important unit quantities which must be studied under unit head :

1. Unit speed, 2. Unit discharge, and 3. Unit power.

18.12.1 Unit Speed. It is defined as the speed of a turbine working under a unit head (*i.e.*, under a head of 1 m). It is denoted by 'N_u'. The expression for unit speed (N_u) is obtained as :

Let N = Speed of a turbine under a head H,

H = Head under which a turbine is working,

u = Tangential velocity.

The tangential velocity, absolute velocity of water and head on the turbine are related as

$$u \propto V, \qquad \text{where } V \propto \sqrt{H}$$

$$\propto \sqrt{H} \qquad ...(i)$$

Also tangential velocity (u) is given by

$$u = \frac{\pi DN}{60}, \qquad \text{where } D = \text{Diameter of turbine.}$$

For a given turbine, the diameter (D) is constant.

$\therefore$ $$u \propto N \text{ or } N \propto u \text{ or } N \propto \sqrt{H} \qquad (\because \text{ From } (i),\ u \propto \sqrt{H})$$

$\therefore$ $$N = K_1 \sqrt{H} \qquad ...(ii)$$

where K_1 is a constant of proportionality.

If head on the turbine becomes unity, the speed becomes unit speed or

when $$H = 1, N = N_u$$

Substituting these values in equation (*ii*), we get

$$N_u = K_1 \sqrt{1.0} = K_1$$

Substituting the value of K_1 in equation (*ii*),

$$N = N_u \sqrt{H} \text{ or } N_u = \frac{N}{\sqrt{H}}. \qquad ...(18.29)$$

18.12.2 Unit Discharge. It is defined as the discharge passing through a turbine, which is working under a unit head (*i.e.*, 1 m). It is denoted by the symbol 'Q_u'. The expression for unit discharge is given as :

Let H = Head of water on the turbine,

Q = Discharge passing through turbine when head is H on the turbine,

a = Area of flow of water.

The discharge passing through a given turbine under a head 'H' is given by,

$$Q = \text{Area of flow} \times \text{Velocity}$$

But for a turbine, area of flow is constant and velocity is proportional to $\sqrt{H}$.

$$\therefore \quad Q \propto \text{Velocity} \propto \sqrt{H}$$

or $$Q = K_2 \sqrt{H} \qquad ...(iii)$$

where K_2 is constant of proportionality.

If $H = 1$, $Q = Q_u$. (By definition)

Substituting these values in equation (*iii*), we get

$$Q_u = K_2 \sqrt{1.0} = K_2.$$

Substituting the value of K_2 in equation (*iii*), we get

$$Q = Q_u \sqrt{H}$$

$$\therefore \quad Q_u = \frac{Q}{\sqrt{H}} \qquad ...(18.30)$$

18.12.3 Unit Power. It is defined as the power developed by a turbine, working under a unit head (*i.e.*, under a head or 1 m). It is denoted by the symbol 'P_u'. The expression for unit power is obtained as :

Let H = Head of water on the turbine,

P = Power developed by the turbine under a head of H,

Q = Discharge through turbine under a head H.

The overall efficiency (η_o) is given as

$$\eta_o = \frac{\text{Power developed}}{\text{Water power}} = \frac{P}{\frac{\rho \times g \times Q \times H}{1000}}$$

$$\therefore \quad P = \eta_o \times \frac{\rho \times g \times Q \times H}{1000}$$

$$\propto Q \times H$$

$$\propto \sqrt{H} \times H \qquad (\because \quad Q \propto \sqrt{H})$$

$$\propto H^{3/2}$$

$$\therefore \quad P = K_3 H^{3/2} \qquad ...(iv)$$

where K_3 is a constant of proportionality.

When $H = 1$ m $\quad P = P_u$

$$\therefore \quad P_u = K_3 (1)^{3/2} = K_3.$$

Substituting the value of K_3 in equation (*iv*), we get

$$P = P_u H^{3/2}$$

$$\therefore \quad P_u = \frac{P}{H^{3/2}}. \qquad ...(18.31)$$

18.12.4 Use of Unit Quantities (N_u, Q_u, P_u). If a turbine is working under different heads, the behaviour of the turbine can be easily known from the values of the unit quantities, *i.e.*, from the values of unit speed, unit discharge and unit power.

Let H_1, H_2, ...are the heads under which a turbine works,
N_1, N_2, ...are the corresponding speeds,
Q_1, Q_2, ...are the discharge, and
P_1, P_2, ...are the power developed by the turbine.

Using equations (18.29), (18.30) and (18.31) respectively,

$$\left.\begin{aligned} N_u &= \frac{N_1}{\sqrt{H_1}} = \frac{N_2}{\sqrt{H_2}} \\ Q_u &= \frac{Q_1}{\sqrt{H_1}} = \frac{Q_2}{\sqrt{H_2}} \\ P_u &= \frac{P_1}{H_1^{3/2}} = \frac{P_2}{H_2^{3/2}} \end{aligned}\right\} \quad ...(18.32)$$

Hence, if the speed, discharge and power developed by a turbine under a head are known, then by using equation (18.32) the speed, discharge and power developed by the same turbine under a different head can be obtained easily.

Problem 18.41 (A) *A turbine develops 9000 kW when running at 10 r.p.m. The head on the turbine is 30 m. If the head on the turbine is reduced to 18 m, determine the speed and power developed by the turbine.*

Solution. Given :

Power developed, $P_1 = 9000$ kW
Speed, $N_1 = 100$ r.p.m.
Head, $H_1 = 30$ m
Let for a head, $H_2 = 18$ m
Speed $= N_2$
Power $= P_2$

Using equation (18.32), $\frac{N_1}{\sqrt{H_1}} = \frac{N_2}{\sqrt{H_2}}$

$$N_2 = \frac{N_1\sqrt{H_2}}{\sqrt{H_1}} = \frac{100\sqrt{18}}{\sqrt{30}} = \frac{100 \times 4.2426}{5.4772} = \mathbf{77.46\ r.p.m.\ Ans.}$$

Also we have $\frac{P_1}{H_1^{3/2}} = \frac{P_2}{H_2^{3/2}}$

$\therefore$ $$P_2 = \frac{P_1 H_2^{3/2}}{H_1^{3/2}} = \frac{9000 \times 18^{3/2}}{30^{3/2}} = \frac{687307.78}{164.316} = \mathbf{4182.84\ kW.\ Ans.}$$

Problem 18.42 *A turbine develops 500 kW power under a head of 100 metres at 200 r.p.m. What would be its normal speed and output under a head of 81 metres ?*

Solution. Given :

Power, $P_1 = 500$ kW
Head, $H_1 = 100$ m

Speed, $N_1 = 200$ r.p.m.
For a head, $H_2 = 81$ m
Let, N_2 = Speed
P_2 = Power
Using equation (18.32) for speed, we have

$$\frac{N_1}{\sqrt{H_1}} = \frac{N_2}{\sqrt{H_2}}$$

$$\therefore \quad N_2 = \sqrt{H_2} \times \frac{N_1}{\sqrt{H_1}} = \sqrt{\frac{H_2}{H_1}} \times N_1 = \sqrt{\frac{81}{100}} \times 200$$

$$= \frac{9}{10} \times 20 = \textbf{180 r.p.m. Ans.}$$

Using equation (18.32) for power, we have

$$\frac{P_1}{H_1^{3/2}} = \frac{P_2}{H_2^{3/2}}$$

$$\therefore \quad P_2 = H_2^{3/2} \times \frac{P_1}{H_1^{3/2}} = \frac{81^{3/2}}{100^{3/2}} \times 500$$

$$= \frac{729}{1000} \times 500 = \textbf{364.5 kW. Ans.}$$

Problem 18.43 *A turbine is to operate under a head of 25 m at 200 r.p.m. The discharge is 9 cumec. If the efficiency is 90%, determine the performance of the turbine under a head of 20 metres.*

Solution. Given :
Head on turbine, $H_1 = 25$ m
Speed, $N_1 = 200$ r.p.m.
Discharge, $Q_1 = 9$ m^3/s
Overall efficiency, $\eta_o = 90\%$ or 0.90.
Performance of the turbine under a head, $H_2 = 20$ m, means to find the speed, discharge and power developed by the turbine when working under the head of 20 m.
Let for the head, $H_2 = 20$ m, Speed = N_2, discharge = Q_2 and power = P_2
Using the relation,

$$\eta_o = \frac{P}{\text{W.P.}} = \frac{p_1}{\frac{\rho \times g \times Q_1 \times H_1}{1000}}$$

$$\therefore \quad P_1 = \frac{\eta_o \times \rho \times g \times Q_1 \times H_1}{1000} = \frac{0.90 \times 1000 \times 9.81 \times 9 \times 25}{1000} = 1986.5 \text{ kW}$$

Using equation (18.32), $\dfrac{N_1}{\sqrt{H_1}} = \dfrac{N_2}{\sqrt{H_2}}$

$$\therefore \quad N_2 = \frac{N_1\sqrt{H_2}}{\sqrt{H_1}} = 200 \times \frac{\sqrt{20}}{\sqrt{25}} = \textbf{178.88 r.p.m. Ans.}$$

Also $$\frac{Q_1}{\sqrt{H_1}} = \frac{Q_2}{\sqrt{H_2}}$$

$\therefore$ $$Q_2 = Q_1 \times \frac{\sqrt{H_2}}{\sqrt{H_1}} = 9.0 \times \sqrt{\frac{20}{25}} = \mathbf{8.05\ m^3/s.\ Ans.}$$

And $$\frac{P_1}{H_1^{3/2}} = \frac{P_2}{H_2^{3/2}}$$

$\therefore$ $$P_2 = \frac{P_1 H_2^{3/2}}{H_1^{3/2}} = P_1 \left(\frac{H_2}{H_1}\right)^{3/2} = 1986.5 \left(\frac{20}{25}\right)^{3/2} = \mathbf{1421.42\ kW.\ Ans.}$$

Problem 18.44 *A Pelton wheel is revolving at a speed of 190 r.p.m. and develops 5150.25 kW when working under a head of 220 m with an overall efficiency of 80%. Determine unit speed, unit discharge and unit power. The speed ratio for the turbine is given as 0.47. Find the speed, discharge and power when this turbine is working under a head of 140 m.*

Solution. Given :

Speed, $N_1 = 190$ r.p.m.
Power, $P_1 = 5150.25$ kW
Head, $H_1 = 220$ m
Overall efficiency, $\eta_o = 80\% = 0.80$
Speed ratio $= 0.47$
New head of water, $H_2 = 140$ m

Overall efficiency is given by $\eta_o = \dfrac{P_1}{\dfrac{\rho \times g \times Q_1 \times H_1}{1000}} = \dfrac{1000 \times P_1}{\rho \times g \times Q_1 \times H_1}$

$\therefore$ $$Q_1 = \frac{1000 \times P_1}{\eta_o \times \rho \times g \times H_1} = \frac{1000 \times 5150.25}{0.80 \times 1000 \times 9.81 \times 220} = 2.983\ \text{m}^3/\text{s}$$

Unit speed is given by equation (18.29),

$$N_u = \frac{N_1}{\sqrt{H_1}} = \frac{190}{\sqrt{220}} = \mathbf{12.81\ r.p.m.\ Ans.}$$

Unit discharge is given by equation (18.30),

$$Q_u = \frac{Q_1}{\sqrt{H_1}} = \frac{2.983}{\sqrt{220}} = \mathbf{0.201\ m^3/s.\ Ans.}$$

Unit power is given by equation (18.31),

$$P_u = \frac{P_1}{H_1^{3/2}} = \frac{5150.25}{220^{3/2}} = \mathbf{1.578\ kW.\ Ans.}$$

When the turbine is working under a new head of 140 m, the speed, discharge and power are given by equation (18.32) as

For speed, $$\frac{N_1}{\sqrt{H_1}} = \frac{N_2}{\sqrt{H_2}}$$

$\therefore$ $$N_2 = \frac{N_1 \sqrt{H_2}}{\sqrt{H_1}} = N_1 \sqrt{\frac{H_2}{H_1}} = 190 \sqrt{\frac{140}{220}} = \mathbf{151.56\ r.p.m.\ Ans.}$$

For discharge, $\frac{Q_1}{\sqrt{H_1}} = \frac{Q_2}{\sqrt{H_2}}$

$\therefore \quad Q_2 = \frac{Q_1\sqrt{H_2}}{\sqrt{H_1}} = Q_1\sqrt{\frac{H_2}{H_1}} = 2.983\sqrt{\frac{140}{220}} = \mathbf{2.379\ m^3/s.\ Ans.}$

For power, $\frac{P_1}{H_1^{3/2}} = \frac{P_2}{H_2^{3/2}}$

$\therefore \quad P_2 = P_1\frac{H_2^{3/2}}{H_1^{3/2}} = P_1\left(\frac{H_2}{H_1}\right)^{3/2} = 5150.25\left(\frac{140}{220}\right)^{3/2} = \mathbf{2614.48\ kW.\ Ans.}$

Problem 18.45 *A Pelton wheel is supplied with water under a head of 35 m at the rate of 40.5 kilo litre/min. The bucket deflects the jet through an angle of 160° and the mean bucket speed is 13 m/s. Calculate the power and hydraulic efficiency of the turbine.*

Solution. Given :

Net head, $H = 35$ m

Discharge, $Q = 40.5$ kilo litre/min

$= 40.5 \times 1000$ litre/min

$= \frac{40.5\times1000}{1000}$ m^3/min $\qquad \left(1\text{ litre} = \frac{1}{1000}\text{m}^3\right)$

$= 40.5$ m^3 / min $= \frac{40.5}{60}$ m^3/s $= 0.675$ m^3/s

Angle of deflection $= 160°$

$\therefore$ Angle, $\phi = 180° - 160° = 20°$

Mean bucket speed, $u = u_1 = u_2 = 13$ m/s

Calculate : (*i*) Power at runner and (*ii*) Hydraulic efficiency.

Taking the value of $C_v = 1.0$

The velocity of jet, $V_1 = C_v\sqrt{2gH} = 1 \times \sqrt{2\times9.81\times35} = 26.2$ m/s

$\therefore \quad V_{r_1} = V_1 - u_1 = 26.2 - 13 = 13.2$ m/s

Also $V_{w_1} = V_1 = 26.2$ m/s

$V_{r_2} = V_{r_1} = 13.2$ m/s

and $V_{w_2} = V_{r_2}\cos\phi - u_2$

$= 13.2 \times \cos 20° - 13 = 12.554 - 13 = -0.446$ m/s

(*i*) *Power at runner*

Using equation (18.9), we get the work done by the jet on the runner per second.

$\therefore$ Work done/s $= \rho \times a \times V_1\left[V_{w_1} + V_{w_2}\right] \times u$

$= \rho \times Q \times \left[V_{w_1} + V_{w_2}\right] \times u \qquad (\because \quad a \times V_1 = Q)$

$$= 1000 \times 0.675\ [26.2 + (-0.446)] \times 13\ \frac{\text{Nm}}{\text{s}} = 225991\ \text{W}$$

($\because$ Nm/s = W)

$$= 225.991\ \text{kW}$$

$\therefore$ Power at runner = **225.991 kW. Ans.**

(*ii*) *Hydraulic efficiency*

Input power in kW is given by equation (18.3*A*).

$\therefore$ Input power $= \dfrac{\rho \times g \times Q \times H}{1000}$, where $\rho = 1000\ \text{kg/m}^3$

$$= \frac{1000 \times 9.81 \times 0.675 \times 35}{1000} = 231.761\ \text{kW}$$

$\therefore$ Hydraulic efficiency $= \dfrac{\text{Power at runner}}{\text{Input power}}$

$$= \frac{225.991}{231.761} = 0.975 = 0.975 \times 100 = \mathbf{97.5\%.\ Ans.}$$

▶ 18.13 CHARACTERISTIC CURVES OF HYDRAULIC TURBINES

Characteristic curves of a hydraulic turbine are the curves, with the help of which the exact behaviour and performance of the turbine under different working conditions, can be known. These curves are plotted from the results of the tests performed on the turbine under different working conditions.

The important parameters which are varied during a test on a turbine are :

1. Speed (N)
2. Head (H)
3. Discharge (Q)
4. Power (P)
5. Overall efficiency (η_o) and
6. Gate opening.

Out of the above six parameters, three parameters namely speed (N), head (H) and discharge (Q) are independent parameters.

Out of the three independent parameters, (N, H, Q) one of the parameter is kept constant (say H) and the variation of the other four parameters with respect to any one of the remaining two independent variables (say N and Q) are plotted and various curves are obtained. These curves are called characteristic curves. The following are the important characteristic curves of a turbine.

1. Main Characteristic Curves or Constant Head Curves.
2. Operating Characteristic Curves or Constant Speed Curves.
3. Muschel Curves or Constant Efficiency Curves.

18.13.1 Main Characteristic Curves or Constant Head Curves. Main characteristic curves are obtained by maintaining a constant head and a constant gate opening (G.O.) on the turbine. The speed of the turbine is varied by changing load on the turbine. For each value of the speed, the corresponding values of the power (P) and discharge (Q) are obtained. Then the overall efficiency (η_o) for each value of the speed is calculated. From these readings the values of unit speed (N_u), unit power (P_u) and unit discharge (O_u) are determined. Taking N_u as abscissa, the values of Q_u, P_u, P and η_o are plotted as shown in Figs. 18.35 and 18.36. By changing the gate opening, the values of Q_u, P_u and η_o and N_u are determined and taking N_u as abscissa, the values of Q_u, P_u and η_o are plotted. Fig. 18.35

shows the main characteristic curves for Pelton wheel and Fig. 18.36 shows the main characteristic curves for reaction (Francis and Kaplan) turbines.

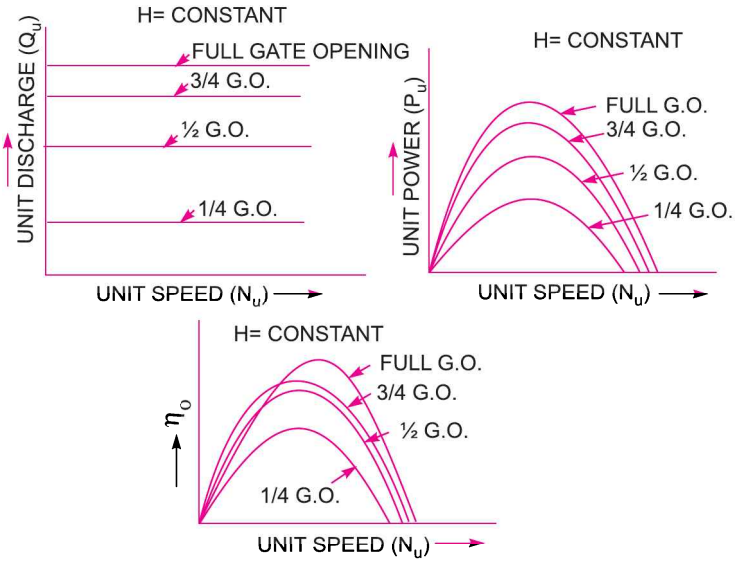

Fig. 18.35 *Main characteristic curves for a Pelton wheel.*

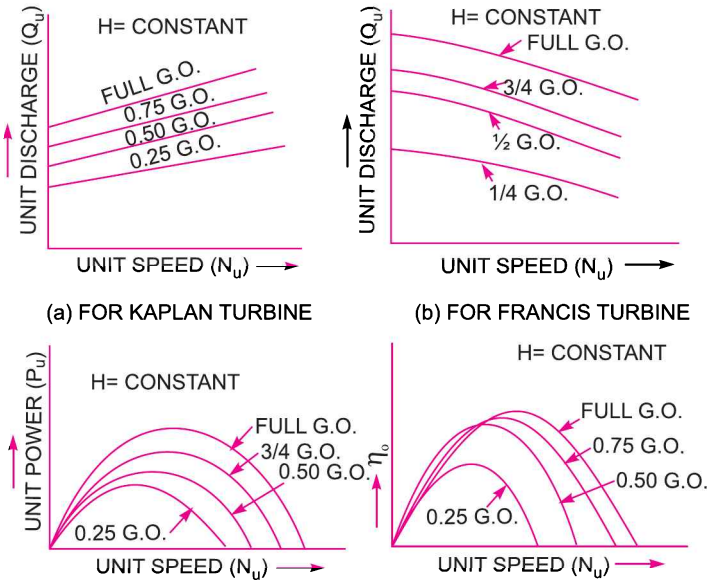

Fig. 18.36 *Main characteristic curves for reaction turbine.*

18.13.2 Operating Characteristic Curves or Constant Speed Curves. Operating characteristic curves are plotted when the speed on the turbine is constant. In case of turbines, the head is generally constant. As mentioned in Art. 18.13, there are three independent parameters namely N, H and Q. For operating characteristics N and H are constant and hence the variation of power and efficiency with respect to discharge Q are plotted. The power curve for turbines shall not pass through

the origin because certain amount of discharge is needed to produce power to overcome initial friction. Hence the power and efficiency curves will be slightly away from the origin on the x-axis, as to overcome initial friction certain amount of discharge will be required. Fig. 18.37 shows the variation of power and efficiency with respect to discharge.

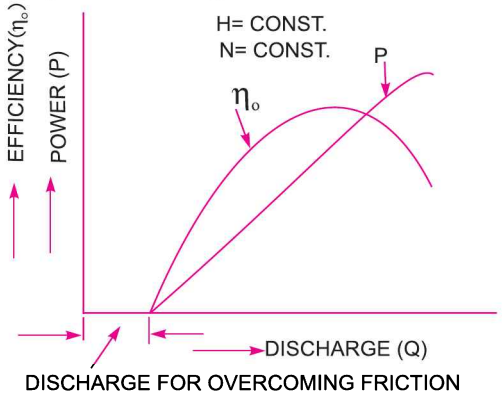

Fig. 18.37 *Operating characteristic curves.*

18.13.3 Constant Efficiency Curves or Muschel Curves or Iso-Efficiency Curves. These curves are obtained from the speed *vs*. efficiency and speed *vs*. discharge curves for different gate openings. For a given efficiency from the N_u *vs*. η_o curves, there are two speeds. From the N_u *vs*. Q_u curves, corresponding to two values of speeds there are two values of discharge. Hence for a given efficiency there are two values of discharge for a particular gate opening. This means for a given efficiency there are two values of speeds and two values of the discharge for a given gate opening. If the efficiency is maximum there is only one value. These two values of speed and two values of discharge corresponding to a particular gate opening are plotted as shown in Fig. 18.38 (*b*). The procedure is repeated for different gate openings and the curves Q *vs*. N are plotted. The points having the same efficiencies are joined. The curves having same efficiency are called iso-efficiency curves. These curves are helpful for determining the zone of constant efficiency and for predicating the performance of the turbine at various efficiencies.

For plotting the iso-efficiency curves, horizontal lines representing the same efficiency are drawn on the η_o ~ speed curves. The points at which these lines cut the efficiency curves at various gate openings are transferred to the corresponding Q ~ speed curves. The points having the same efficiency are then joined by a smooth curves. These smooth curves represents the iso-efficiency curve.

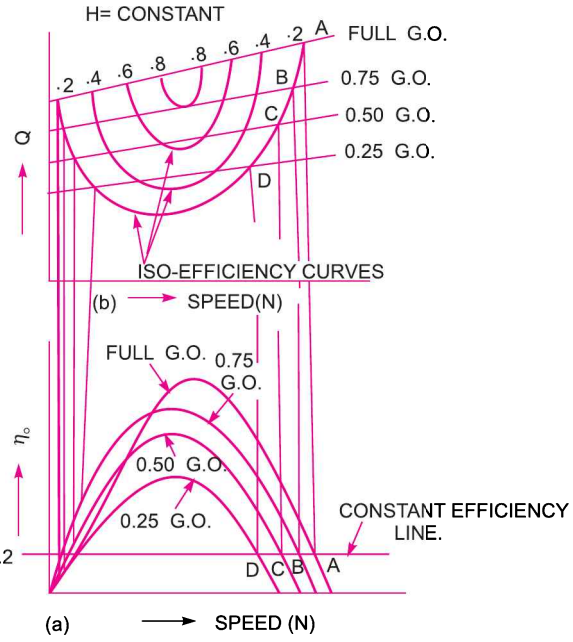

Fig. 18.38 *Constant efficiency curve.*

▶ 18.14 GOVERNING OF TURBINES

The governing of a turbine is defined as the operation by which the speed of the turbine is kept constant under all conditions of working. It is done automatically by means of a governor, which regulates the rate of flow through the turbines according to the changing load conditions on the turbine.

Governing of a turbine is necessary as a turbine is directly coupled to an electric generator, which is required to run at constant speed under all fluctuating load conditions. The frequency of power generation by a generator of constant number of pair of poles under all varying conditions should be constant. This is only possible when the speed of the generator, under all changing load condition, is constant. The speed of the generator will be constant, when the speed of the turbine (which is coupled to the generator) is constant.

When the load on the generator decreases, the speed of the generator increases beyond the normal speed (constant speed). Then the speed of the turbine also increases beyond the normal speed. If the turbine or the generator is to run at constant (normal) speed, the rate of flow of water to the turbine should be decreased till the speed becomes normal. This process by which the speed of the turbine (and hence of generator) is kept constant under varying condition of load is called governing.

Governing of Pelton Turbine (Impulse Turbine)

Governing of Pelton turbine is done by means of oil pressure governor, which consists of the following parts :

1. Oil sump.
2. Gear pump also called oil pump, which is driven by the power obtained from turbine shaft.
3. The Servomotor also called the relay cylinder.
4. The control valve or the distribution valve or relay valve.
5. The centrifugal governor or pendulum which is driven by belt or gear from the turbine shaft.
6. Pipes connecting the oil sump with the control valve and control valve with servomotor and
7. The spear rod or needle.

Fig. 18.39 shows the position of the piston in the relay cylinder, position of control or relay valve and fly-balls of the centrifugal governor, when the turbine is running at the normal speed.

When the load on the generator decreases, the speed of the generator increases. This increases the speed of the turbine beyond the normal speed. The centrifugal governor, which is connected to the turbine main shaft, will be rotating at an increased speed . Due to increase in the speed of the centrifugal governor, the fly-balls move upward due to the increased centrifugal force on them. Due to the upward movement of the fly-balls, the sleeve will also move upward. A horizontal lever, supported over a fulcrum, connects the sleeve and the piston rod of the control valve. As the sleeve moves up, the lever turns about the fulcrum and the piston rod of the control valve moves downward. This closes the valve V_1 and opens the valve V_2 as shown in Fig. 18.39.

The oil, pumped from the oil pump to the control valve or relay valve, under pressure will flow through the valve V_2 to the servomotor (or relay cylinder) and will exert force on the face A of the piston of the relay cylinder. The piston along with piston rod and spear will move towards right. This will decrease the area of flow of water at the outlet of the nozzle. This decrease of area of flow will reduce the rate of flow of water to the turbine which consequently reduces the speed of the turbine. When the speed of the turbine becomes normal, the fly-balls, sleeve, lever and piston rod of control valve come to its normal position as shown in Fig. 18.39.

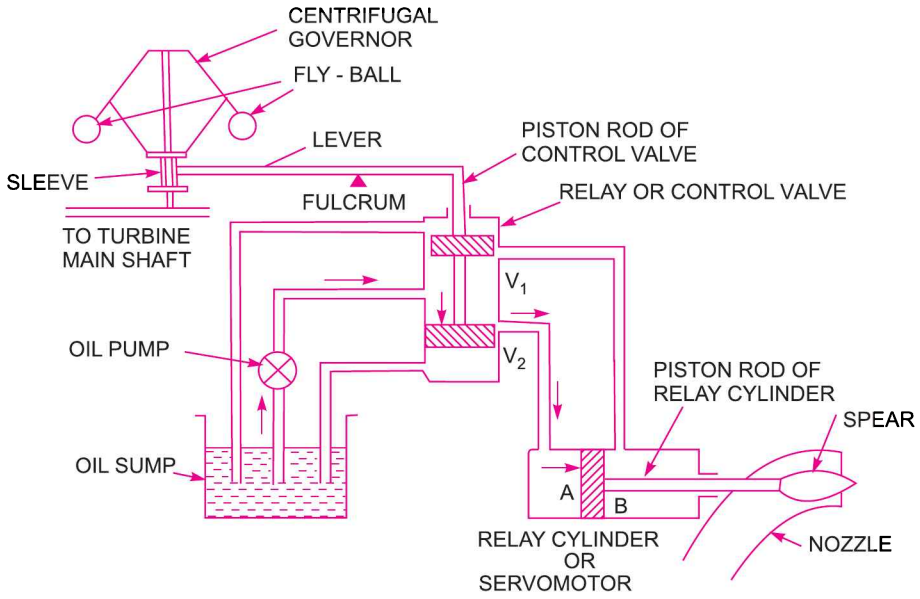

Fig. 18.39. *Governing of Pelton turbine.*

When the load on the generator increases, the speed of the generator and hence of the turbine decreases. The speed of the centrifugal governor also decreases and hence centrifugal force acting on the fly-balls also reduces. This brings the fly-balls in the downward direction. Due to this, the sleeve moves downward and the lever turns about the fulcrum, moving the piston rod of the control valve in the upward direction. This closes the valve V_2 and opens the valve V_1. The oil under pressure from the control valve, will move through valve V_1 to the servomotor and will exert a force on the face B of the piston. This will move the piston along with the piston rod and spear towards left, increasing the area of flow of water at the outlet of the nozzle. This will increase the rate of flow of water to the turbine and consequently, the speed of the turbine will also increase, till the speed of the turbine becomes normal.

HIGHLIGHTS

1. The hydraulic machines, which convert the hydraulic energy into mechanical energy, are called turbines.
2. Gross head is the vertical difference between the head race and tail race levels. Net head or effective head is the head, available at the inlet of the turbine. It is given by

$$H = H_g - h_f$$

where H_g = Gross head, and

h_f = Loss of head due to friction in penstocks

$$= \frac{4f \times L \times V^2}{D \times 2g}$$

where D = Dia. of penstock.

3. The efficiencies of a turbine are : (*i*) Hydraulic efficiency, η_h, (*ii*) Mechanical efficiency, η_m, and (*iii*) Overall efficiency, η_o.
4. Hydraulic efficiency, η_h is given by

$$\eta_h = \frac{\text{Power delivered to runner}}{\text{Power supplied at inlet}} = \frac{\text{R.P.}}{\text{W.P.}}$$

$$= \frac{W}{g}\frac{(V_{w_1}u_1 \pm V_{w_2}u_2)}{1000} \Big/ \frac{(W \times H)}{1000} = \frac{(V_{w_1}u_1 \pm V_{w_2}u_2)}{gH}$$

where W.P. = Water power,
R.P. = Runner power *i.e.*, power available at the runner of the turbine,
S.P. = Shaft power *i.e.*, power at the shaft of the turbine.

5. Mechanical efficiency, η_m is given by $\eta_m = \frac{\text{S.P.}}{\text{R.P.}}$

6. Overall efficiency, η_o is given by $\eta_o = \frac{\text{S.P.}}{\text{W.P.}} = \eta_m \times \eta_h$.

7. If at the inlet of a turbine, the energy available is only kinetic energy, the turbine is known as impulse turbine. But if at the inlet of the turbine, the energy available is kinetic energy as well as pressure energy, the turbine is called reaction turbine.

8. Pelton wheel (or turbine) is a tangential flow impulse turbine and is used for high head. In this turbine,

$$V_1 = C_v\sqrt{2gH}\ , u_1 = u_2 = u.$$

9. For the maximum efficiency of Pelton wheel the condition is $u = \frac{V_1}{2}$

Max. efficiency is given by $\eta_{\max} = \frac{(1+\cos\phi)}{2}$, where ϕ = Vane angle at outlet.

10. The jet ratio (m) is defined as ratio of the pitch diameter (D) of the Pelton wheel to the diameter of the jet (d) or $m = \frac{D}{d}$.

11. Francis turbine is an inward radial flow reaction turbine having discharge radial at outlet, which means the angle made by absolute velocity at outlet is 90°, *i.e.*, $\beta = 90°$. Then $V_{w_2} = 0$ and work done by water on the runner per second per unit weight of water becomes as $= \frac{1}{g}V_{w_1} \times u_1$.

12. Speed ratio is the ratio of the velocity of wheel at inlet to the velocity given by $\sqrt{2gH}$ whereas the flow ratio is the ratio of velocity of flow at inlet to the velocity given by $\sqrt{2gH}$.

13. Kaplan turbine is an axial flow reaction turbine in which the vanes on the hub are adjustable. The peripheral velocity at inlet and outlet are equal, *i.e.*, $u_1 = u_2$.

14. The discharge through a turbine is given by

$$Q = \frac{\pi}{4}d^2 \times \sqrt{2gH} \qquad \text{...For a Pelton wheel}$$

$$= \pi D_1 B_1 \times V_{f_1} \qquad \text{...For a Francis turbine}$$

$$= \frac{\pi}{4}(D_o^2 - D_b^2) \times V_{f_1} \qquad \text{...For a Kaplan turbine.}$$

15. Draft-tube is a pipe of gradually increasing area used for discharging water from the exit of a reaction turbine. They may be conical or simple elbow type. The efficiency of the draft-tube is given by

$$\eta_d = \frac{\left(\frac{V_1}{2g} - \frac{V_2^2}{2g}\right) - h_f}{\left(\frac{V_1^2}{2g}\right)}$$

where V_1 = Velocity of water at the inlet of the draft-tube,
V_2 = Velocity of water at the outlet of the draft-tube,
h_f = Loss of head in draft-tube.

16. Specific speed of a turbine is defined as the speed at which a turbine runs when it is working under a unit head and develops unit power. The expression for specific speed (N_s) is given as

$$N_s = \frac{N\sqrt{P}}{H^{5/4}}$$

where P = shaft power in kW, H = Net head on the turbine.

17. Unit quantities are the quantities (like speed, discharge, power, etc.) which are obtained when the head on the turbine is unity. They are unit speed (N_u), unit power (P_u) and unit discharge (Q_u). They are given as

$$N_u = \frac{N}{\sqrt{H}}, \; Q_u = \frac{Q}{\sqrt{H}}, \; P_u = \frac{P}{H^{3/2}} \; .$$

18. The important characteristic curves of a turbine are :
(*a*) Main characteristic curves or Constant head curves.
(*b*) Operating characteristic curves or Constant speed curves, and
(*c*) Muschel curves or Constant efficiency curves.

19. Governing of a turbine is defined as the operation by which the speed of the turbine is kept constant under all conditions of working. It is done by oil pressure governor.

EXERCISE

(A) THEORETICAL PROBLEMS

1. Define the terms : Hydraulic machines, Turbines and Pumps.

2. Differentiate between the turbines and pumps.

3. (*a*) What do you mean by gross head, net head and efficiency of turbine ? Explain the different types of the efficiency of a turbine.
(*b*) Explain clearly the following terms as they are applied to a Pelton wheel :
(*i*) Gross head ; (*ii*) Net head.

4. How will you classify the turbines ?

5. Differentiate between : (*a*) The impulse and reaction turbines, (*b*) Radial and axial flow turbines, (*c*) Inward and outward radial flow turbine, and (*d*) Kaplan and propeller turbines.

6. Obtain an expression for the work done per second by water on the runner of a Pelton wheel. Hence derive an expression for maximum efficiency of the Pelton wheel giving the relationship between the jet speed and bucket speed.
Draw inlet and outlet velocity triangles for a Pelton turbine and indicate the direction of various velocities.

7. Prove that the work done per second per unit weight of water in a reaction turbine is given as

$$= \frac{1}{g}(V_{w_1} u_1 \pm V_{w_2} u_2)$$

where V_{w_1} and V_{w_2} = Velocities of whirl at inlet and outlet,

u_1 and u_2 = Peripheral velocities at inlet and outlet.

8. Define the terms : speed ratio, flow ratio and jet ratio.
9. (*a*) What is a draft-tube ? Why is it used in a reaction turbine ? Describe with sketch two different types of draft-tubes.
   (*b*) What are the uses of a draft-tube ? Describe with neat sketches different types of draft-tubes. (*J.N.T.U., Hyderabad S 2002*).
10. What is the basis of selection of a turbine at a particular place ?
11. Define the specific speed of a turbine ? Derive an expression for the specific speed. What is the significance of the specific speed?
12. What are unit quantities ? Define the unit quantities for a turbine. Why are they important ?
13. Obtain an expression for unit speed, unit discharge and unit power for a turbine.
14. What do you understand by the characteristic curves of a turbine ? Name the important types of characteristic curves.
15. Define the term 'Governing of a turbine'. Describe with a neat sketch the working of an oil pressure governor.
16. Give the range of specific speed values of the Kaplan, Francis turbines and Pelton wheels.
    What factors decide whether Kaplan, Francis, or a Pelton type turbine would be used in a hydroelectric project ?
17. (*a*) Draw neat sketches of the Pelton turbine and Francis Turbine.
    (*b*) Describe briefly the function of various main components of Pelton turbine with neat sketches.
18. What is cavitation ? How can it be avoided in reaction turbine ?
19. Define the terms 'unit power', 'unit speed ' and 'unit discharge' with reference to a hydraulic turbine. Also derive expressions for these terms.
20. (*a*) Define specific speed of a turbine and derive an expression for the same. Show that Pelton turbine is a low specific speed turbine.
    (*b*) What is specific speed ? State its significance in the study of hydraulic machines.
21. (*a*) By means of a neat sketch explain the governing mechanism of Francis Turbine.
    (*b*) Explain the difference between Kaplan turbine and propeller turbine.
22. Define and explain hydraulic efficiency, mechanical efficiency and overall efficiency of a turbine.
23. Define the terms : specific speed of a turbine, unit speed, unit power and unit rate of flow of a turbine. Derive the expressions for specific speed and unit speed.
24. (*a*) What is meant by the speed ratio of a Pelton wheel ?
    (*b*) What is a draft-tube ? What are its functions ?
    (*c*) Differentiate between an inward and an outward flow reaction turbine.

(B) NUMERICAL PROBLEMS

1. A Pelton wheel has a mean bucket speed of 35 m/s with a jet of water flowing at the rate of 1 m^3/s under a head of 270 m. The buckets deflect the jet through an angle of 170° . Calculate the power delivered to the runner and the hydraulic efficiency of the turbine. Assume co-efficient of velocity as 0.98.
   [**Ans.** 2523.8 kW, 95.3%]
2. A Pelton wheel is to be designed for the following specifications. Power = 735.75 kW, S.P. Head = 200 m, Speed = 800 r.p.m. , η_o = 0.86 and jet diameter is not to exceed one-tenth the wheel diameter.
   Determine : (*i*) Wheel diameter, (*ii*) The number of jets required, and (*iii*) Diameter of the jet. Take C_v = 0.98 and speed ratio = 0.45. [**Ans.** (*i*) 0.673 m, (*ii*) 2, (*iii*) 67.3 mm]

3. A Pelton wheel is having a mean bucket diameter of 0.8 m and is running at 1000 r.p.m. The net head on the Pelton wheel is 400 m. If the side clearance angle is 15° and discharge through nozzle is 150 litres/s, find : (*i*) Power available at the nozzle, and (*ii*) Hydraulic efficiency of the turbine.

[**Ans.** (*i*) 588.6 kW, (*ii*) 98%]

4. Two jets strike at buckets of a Pelton wheel, which is having shaft power as 14,715 kW. The diameter of each jet is given as 150 mm. If the net head on the turbine is 500 m, find the overall efficiency of the turbine. Take $C_v = 1.0$. [**Ans.** 85.7%]

5. The following data is related to the Pelton wheel :

Head at the base of the nozzle = 110 m,
Diameter of the jet = 7.5 cm,
Discharge of the nozzle = 200 litres/s,
Shaft power = 191.295 kW
Power absorbed in mechanical resistance = 3.675 kW.

Determine : (*i*) Power lost in nozzle and, (*ii*) Power lost due to hydraulic resistance in the runner.

[**Ans.** (*i*) 10.874 kW, (*ii*) 9.97 kW]

6. Design a Pelton wheel for a head of 80 m and speed 300 r.p.m. The Pelton wheel develops 103 kW S.P. Take $C_v = 0.98$, speed ratio = 0.45 and overall efficiency = 0.80.

[**Ans.** $D = 1.135$ m, $d = 72.6$ mm, size = 36.3×8.7, $Z = 23$]

7. An inward flow reaction turbine has external and internal diameters as 1.2 m and 0.6 m respectively. The velocity of flow through the runner is constant and is equal to 1.8 m/s. Determine : (*i*) Discharge through the runner, and (*ii*) Width at outlet if the width at inlet = 200 mm. [**Ans.** (*i*) 1.357 m^3/s, (*ii*) 400 mm]

8. A reaction turbine works at 500 r.p.m. under a head of 100 m. The diameter of turbine at inlet is 100 cm and flow area is 0.35 m^2. The angles made by absolute and relative velocities at inlet are 15° and 60° respectively with the tangential velocity. Determine :
(*i*) The volume flow rate, (*ii*) The power developed, and (*iii*) Efficiency. Assume whirl at outlet to be zero.

[**Ans.** (*i*) 2.905 m^3/s, (*ii*) 2355.35 kW, (*iii*) 82.6%]

9. An inward flow reaction turbine has an external diameter of 1 m and its breadth at inlet is 200 mm. If the velocity of flow at inlet is 1.5 m/s, find the mass of water passing through the turbine per second. Assume 15% of the area of flow is blocked by blade thickness. If the speed of the runner is 200 r.p.m. and guide blades make an angle of 15° to the wheel tangent, draw the inlet velocity triangle and find : (*i*) The runner vane angle at inlet (*ii*) Velocity of wheel at inlet, (*iii*) The absolute velocity of water leaving the guide vanes, and (*iv*) The relative velocity of water entering the runner blade.

[**Ans.** 1602.2 kg/s, (*i*) 76.19, (*ii*) 10.47 m/s, (*iii*) 11.59 m/s, (*iv*) 3.087 m/s]

10. An outward flow reaction turbine has internal and external diameters of the runner as 0.5 m and 1.0 m respectively. The guide blade angle is 15° and velocity of flow through the runner is constant and equal to 3 m/s. If the speed of the turbine is 250 r.p.m., head on turbine is 10 m and discharge at outlet is radial, determine : (*i*) The runner vane angles at inlet and outlet, (*ii*) Work done by the water on the runner per second per unit weight of water striking per second and (*iii*) Hydraulic efficiency.

[**Ans.** (*i*) 32° 48′, 12° 55′, (*ii*) 7.47 m, (*iii*) 7.47%]

11. A Francis turbine with an overall efficiency of 70% is required to produce 147.15 kW. It is working under a head of 8 m. The peripheral velocity = $0.30\sqrt{2gH}$ and the radial velocity of flow at inlet is $0.96\sqrt{2gH}$. The wheel runs at 200 r.p.m. and the hydraulic losses in the turbine are 20% of the available energy. Assume radial discharge, determine : (*i*) The guide blade angle, (*ii*) The wheel vane angle at inlet, (*iii*) Diameter of the wheel at inlet, and (*iv*) Width of wheel at inlet.

[**Ans.** (*i*) 35° 45′,(*ii*) 42° 54′, (*iii*) 35.9 cm, (*iv*) 19.75 cm]

12. The following data is given for a Francis turbine : Net head = 70 m, speed = 600 r.p.m., shaft power = 367.875 kW, $\eta_o = 85\%$, $\eta_h = 95\%$, flow ratio = 0.25, breadth ratio = 0.1, outer diameter of the runner = 2 × inner diameter of runner. The thickness of vanes occupy 10% of the circumferential area of the

runner. Velocity of flow is constant at inlet and outlet and discharge is radial at outlet. Determine : (*i*) Guide blade angle, (*ii*) Runner vane angles at inlet and outlet, (*iii*) Diameters of runner at inlet and outlet, and (*iv*) Width of wheel at inlet.

[**Ans.** (*i*) 12° 20′, (*ii*) 18° 57′, 50° 17′, (*iii*) .49,.245 m, (*iv*) 49 mm]

13. A Kaplan turbine working under a head of 15 m develops 7357.5 kW shaft power. The outer diameter of the runner is 4 m and hub diameter is 2 m. The guide blade angle at the extreme edge of the runner is 30°. The hydraulic and overall efficiencies of the turbine are 90% and 85% respectively. If the velocity of whirl is zero at outlet, detemine : (*i*) runner vane angles at inlet and outlet at the extreme edge of the runner and (*ii*) speed of the turbine. [**Ans.** (*i*) 103° 10′, 26° 58.5′, (*ii*) 58.5]

14. A Kaplan turbine runner is to be designed to develop 7357.5 kW S.P. The net available head is 10 m. Assume that the speed ratio is 1.8 and flow ratio is 0.6. If the overall efficiency is 70% and diameter of the boss is 0.4 times the diameter of the runner, find the diameter of the runner, its speed and specific speed.

[**Ans.** 4.39 m, 109.63 r.p.m., 528.82]

15. A conical draft-tube having inlet and outlet diameters 0.8 m and 1.2 m discharges water at outlet with a velocity of 3 m/s. The total length of the draft-tube is 8 m and 2 m of the length of draft-tube is immersed in water. If the atmospheric pressure head is 10.3 m of water and loss of head due to friction in the draft-tube is equal to 0.25 times the velocity head at outlet of the tube, find : (*i*) Pressure head at inlet, and (*ii*) Efficiency of the draft-tube. [**Ans.** (*i*) 2.551 m (abs.), (*ii*) 75.3%]

16. A turbine is to operate under a head of 30 m at 300 r.p.m. The discharge is 10 m^3/s. If the efficiency is 90%, determine : (*i*) specific speed of the machine, (*ii*) power generated, and (*iii*) types of the turbine.

[**Ans.** (*i*) 219.9, (*ii*) 2648.7 kW (*iii*) Francis]

17. A turbine develops 7357.5 kW S.P. when running at 200 r.p.m. The head on the turbine is 40 m. If the head on the turbine is reduced to 25 m, determine the speed and power developed by the turbine.

[**Ans.** 158.11, 3635.34 kW]

18. A Pelton wheel is revolving at a speed of 200 r.p.m. and develops 5886 kW S.P. when working under a head of 200 m with an overall efficiency of 80%. Determine unit speed, unit discharge and unit power . The speed ratio for the turbine is given as 0.48. Find the speed, discharge and power when this turbine is working under a head of 150 m.

[**Ans.** 14.14, 0.265 m^3/s, 2.08 kW and 173.2 r.p.m., 3.247 m^3/s, 3823 kW]

19. A Kaplan turbine working under a head of 29 m develops 1287.5 kW S.P. If the speed ratio is equal to 2.1, flow ratio = 0.62, diameter of boss = 0.34 times the diameter of the runner and overall efficiency of the turbine = 89%, find the diameter of the runner and the speed of turbine. [**Ans.** 0.705 m, 1162.3]

20. A Kaplan turbine working under a head of 25 m develops 16000 kW shaft power. The outer diameter of the runner is 4 m and hub diameter is 2 m . The guide blade angle is 35°. The hydraulic and overall efficiency are 90% and 85% respectively. If the velocity of whirl is zero at outlet, determine runner vane angles at inlet and outlet, and speed of turbine. [**Ans.** 35° 27′, 88° 36′, 9.236]

21. A Kaplan turbine develops 9000 kW under a net head of 7.5 m. Mechanical efficiency of the wheel is 86%. The speed ratio based on the outer diameter is 2.2 and the flow ratio is 0.66. Diameter of the boss is 0.35 times the external diameter of the wheel. Determine the diameter of the runner and the specific speed of the runner. (*J.N.T.U., Hyderabad, S 2002*)

[**Hint.** Given : S.P. = 9000 kW; $H = 7.5$ m ; $\eta_m = 86\% = 0.86$; Speed ratio = 2.2 ;
flow ratio = 0.66 ; Dia. of boss = 0.35 × External dia. of wheel *i.e.*, $D_b = 0.35\, D_o$.

$$\frac{u_1}{\sqrt{2gH}} = 2.2 \quad \therefore \quad u_1 = 2.2 \times \sqrt{2gH} = 2.2 \times \sqrt{2 \times 9.81 \times 7.5} = 26.68 \text{ m/s}$$

$$\frac{V_{f_1}}{\sqrt{2gH}} = 0.66 \therefore V_{f_1} = 0.66 \times \sqrt{2gH} = 0.66 \times \sqrt{2 \times 9.81 \times 7.5} = 8 \text{ m/s}$$

Note. In this question either data is incomplete or instead of mechanical efficiency it should be overall efficiency. The question is solved taking the given efficiency as overall efficiency.

Now $\eta_o = 0.86$ But $\eta_o = \dfrac{\text{S.P.}}{\text{W.P.}}$ $\therefore$ $\text{W.P.} = \dfrac{\text{S.P.}}{\eta_o} = \dfrac{9000}{0.86}$ kW

But $\text{W.P.} = \dfrac{\rho \times Q \times g \times H}{1000}$ kW $= \dfrac{1000 \times Q \times 9.81 \times 7.5}{1000} = Q \times 9.81 \times 7.5$ kW

$\therefore Q \times 9.81 \times 7.5 = \dfrac{9000}{0.86}$ or $Q = \dfrac{9000}{0.86} \times \dfrac{1}{9.81 \times 7.5} = 142.237$ m^3/s

But $\text{Q} = \dfrac{\pi}{4}\left[D_o^2 - D_b^2\right] \times V_{f_1}$ $\therefore$ $142.237 = \dfrac{\pi}{4}\left[D_o^2 - D_b^2\right] \times V_{f_1} = \dfrac{\pi}{4}[D_o^2 - (0.35D_o)^2] \times 8$

or $142.237 = \dfrac{\pi}{4} \times 0.8775\, D_o^2 \times 8$ or $D_o = \sqrt{\dfrac{142.237 \times 4}{\pi \times 0.8775 \times 8}} = 5.079$ m $\simeq$ **5 m.**

Specific speed of turbine, $N_s = \dfrac{N\sqrt{\text{S.P.}}}{H^{5/4}}$, where N is obtained from u_1

$\therefore$ $u_1 = \dfrac{\pi D_o N}{60}$ or $26.68 = \dfrac{\pi \times 5 \times N}{60}$ or $N = \dfrac{26.68 \times 60}{\pi \times 5} = 101.91$ r.p.m.

$\therefore$ $N_s = \dfrac{101.91 \times \sqrt{9000}}{7.5^{1.25}} =$ **778.95]**

19 CHAPTER

CENTRIFUGAL PUMPS

▶ 19.1 INTRODUCTION

The hydraulic machines which convert the mechanical energy into hydraulic energy are called pumps. The hydraulic energy is in the form of pressure energy. If the mechanical energy is converted into pressure energy by means of centrifugal force acting on the fluid, the hydraulic machine is called centrifugal pump.

The centrifugal pump acts as a reverse of an inward radial flow reaction turbine. This means that the flow in centrifugal pumps is in the radial outward directions. The centrifugal pump works on the principle of forced vortex flow which means that when a certain mass of liquid is rotated by an external torque, the rise in pressure head of the rotating liquid takes place. The rise in pressure head at any point of the rotating liquid is proportional to the square of tangential velocity of the liquid at that point $\left(i.e.,\text{ rise in pressure head } = \frac{V^2}{2g} \text{ or } \frac{\omega^2 r^2}{2g}\right)$. Thus at the outlet of the impeller, where radius is more, the rise in pressure head will be more and the liquid will be discharged at the outlet with a high pressure head. Due to this high pressure head, the liquid can be lifted to a high level.

▶ 19.2 MAIN PARTS OF A CENTRIFUGAL PUMP

The following are the main parts of a centrifugal pump :

1. Impeller.
2. Casing.
3. Suction pipe with a foot valve and a strainer.
4. Delivery pipe.

All the main parts of the centrifugal pump are shown in Fig. 19.1.

1. Impeller. The rotating part of a centrifugal pump is called 'impeller'. It consists of a series of backward curved vanes. The impeller is mounted on a shaft which is connected to the shaft of an electric motor.

2. Casing. The casing of a centrifugal pump is similar to the casing of a reaction turbine. It is an air-tight passage surrounding the impeller and is designed in such a way that the kinetic energy of the water discharged at the outlet of the impeller is converted into pressure energy before the water leaves the casing and enters the delivery pipe. The following three types of the casings are commonly adopted :

(*a*) Volute casing as shown in Fig. 19.1.
(*b*) Vortex casing as shown in Fig. 19.2 (*a*).
(*c*) Casing with guide blades as shown in Fig. 19.2 (*b*).

(*a*) **Volute Casing.** Fig 19.1 shows the volute casing, which surrounds the impeller. It is of spiral type in which area of flow increases gradually. The increase in area of flow decreases the velocity of flow. The decrease in velocity increases the pressure of the water flowing through the casing. It has been observed that in case of volute casing, the efficiency of the pump increases slightly as a large amount of energy is lost due to the formation of eddies in this type of casing.

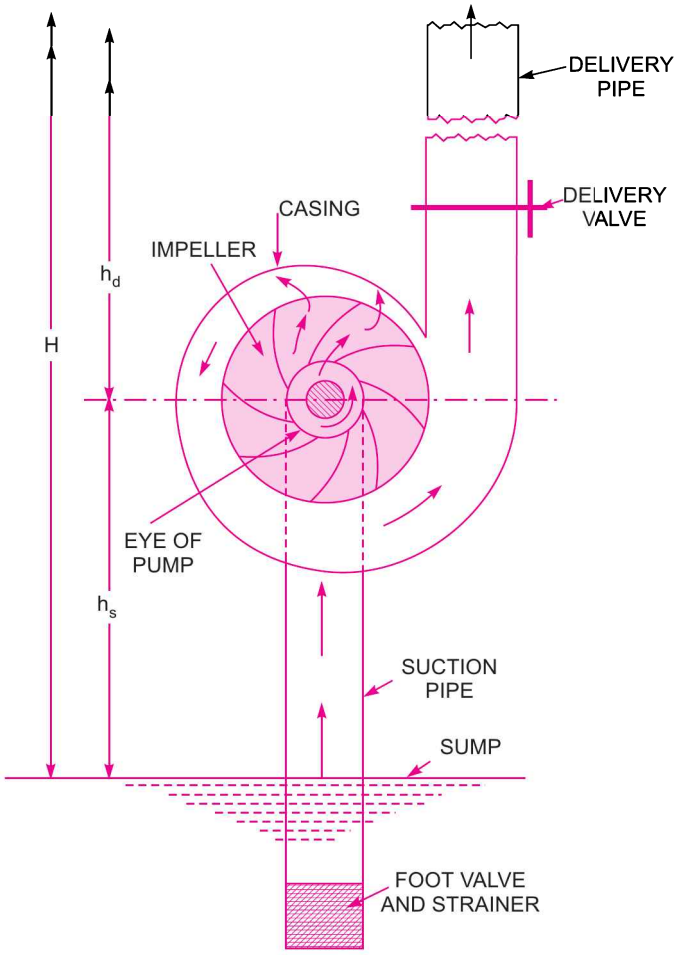

Fig. 19.1 *Main parts of a centrifugal pump.*

(*b*) **Vortex Casing.** If a circular chamber is introduced between the casing and the impeller as shown in Fig. 19.2 (*a*), the casing is known as Vortex Casing. By introducing the circular chamber, the loss of energy due to the formation of eddies is reduced to a considerable extent. Thus the efficiency of the pump is more than the efficiency when only volute casing is provided.

(*c*) **Casing with Guide Blades.** This casing is shown in Fig. 19.2 (*b*) in which the impeller is surrounded by a series of guide blades mounted on a ring which is known as diffuser. The guide vanes are designed in such a way that the water from the impeller enters the guide vanes without stock.

Also the area of the guide vanes increases, thus reducing the velocity of flow through guide vanes and consequently increasing the pressure of water. The water from the guide vanes then passes through the surrounding casing which is in most of the cases concentric with the impeller as shown in Fig. 19.2 (*b*).

3. Suction Pipe with a Foot valve and a Strainer. A pipe whose one end is connected to the inlet of the pump and other end dips into water in a sump is known as suction pipe. A foot valve which is a non-return valve or one-way type of valve is fitted at the lower end of the suction pipe. The foot valve opens only in the upward direction. A strainer is also fitted at the lower end of the suction pipe.

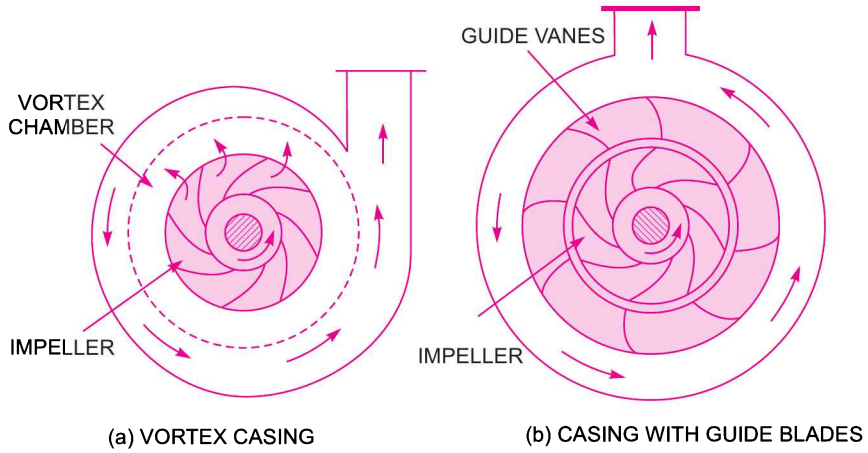

Fig. 19.2 *Different types of casing.*

4. Delivery Pipe. A pipe whose one end is connected to the outlet of the pump and other end delivers the water at a required height is known as delivery pipe.

▶ 19.3 WORK DONE BY THE CENTRIFUGAL PUMP (OR BY IMPELLER) ON WATER

In case of the centrifugal pump, work is done by the impeller on the water. The expression for the work done by the impeller on the water is obtained by drawing velocity triangles at inlet and outlet of the impeller in the same way as for a turbine. The water enters the impeller radially at inlet for best efficiency of the pump, which means the absolute velocity of water at inlet makes an angle of 90° with the direction of motion of the impeller at inlet. Hence angle $\alpha = 90°$ and $V_{w_1} = 0$. For drawing the velocity triangles, the same notations are used as that for turbines. Fig. 19.3 shows the velocity triangles at the inlet and outlet tips of the vanes fixed to an impeller.

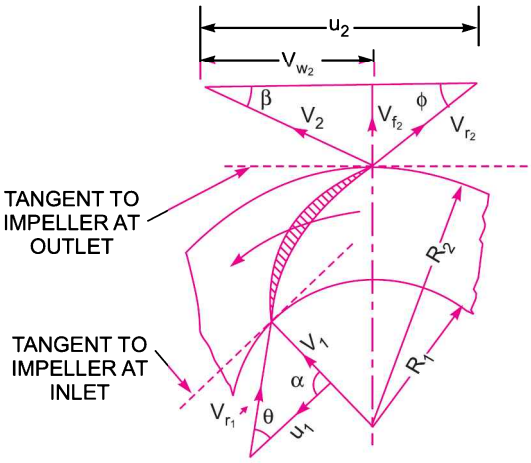

Fig. 19.3 *Velocity triangles at inlet and outlet.*

Let N = Speed of the impeller in r.p.m.,

D_1 = Diameter of impeller at inlet,

u_1 = Tangential velocity of impeller at inlet,

$$= \frac{\pi D_1 N}{60}$$

D_2 = Diameter of impeller at outlet,

u_2 = Tangential velocity of impeller at outlet

$$= \frac{\pi D_2 N}{60}$$

V_1 = Absolute velocity of water at inlet,

V_{r_1} = Relative velocity of water at inlet,

α = Angle made by absolute velocity (V_1) at inlet with the direction of motion of vane,

θ = Angle made by relative velocity (V_{r_1}) at inlet with the direction of motion of vane, and V_2, V_{r_2}, β and ϕ are the corresponding values at outlet.

As the water enters the impeller radially which means the absolute velocity of water at inlet is in the radial direction and hence angle $\alpha = 90°$ and $V_{w_1} = 0$.

A centrifugal pump is the reverse of a radially inward flow reaction turbine. But in case of a radially inward flow reaction turbine, the work done by the water on the runner per second per unit weight of the water striking per second is given by equation (18.19) as

$$= \frac{1}{g}[V_{w_1}u_1 - V_{w_2}u_2]$$

$\therefore$ Work done by the impeller on the water per second per unit weight of water striking per second

$$= - [\text{Work done in case of turbine}]$$

$$= -\left[\frac{1}{g}\left(V_{w_1}u_1 - V_{w_2}u_2\right)\right] = \frac{1}{g}\left[V_{w_2}u_2 - V_{w_1}u_1\right]$$

$$= \frac{1}{g}V_{w_2}u_2 \qquad (\because \quad V_{w_1} = 0 \text{ here}) \quad ...(19.1)$$

Work done by impeller on water per second

$$= \frac{W}{g}.V_{w_2}u_2 \qquad ...(19.2)$$

where W = Weight of water = $\rho \times g \times Q$

where Q = Volume of water

and Q = Area × Velocity of flow = $\pi D_1 B_1 \times V_{f_1}$

$$= \pi D_2 B_2 \times V_{f_2} \qquad ...(19.2A)$$

where B_1 and B_2 are width of impeller at inlet and outlet and V_{f_1} and V_{f_2} are velocities of flow at inlet and outlet.

Equation (19.1) gives the head imparted to the water by the impeller or energy given by impeller to water per unit weight per second.

▶ 19.4 DEFINITIONS OF HEADS AND EFFICIENCIES OF A CENTRIFUGAL PUMP

1. Suction Head (h_s). It is the vertical height of the centre line of the centrifugal pump above the water surface in the tank or pump from which water is to be lifted as shown in Fig. 19.1. This height is also called suction lift and is denoted by 'h_s'.

2. Delivery Head (h_d). The vertical distance between the centre line of the pump and the water surface in the tank to which water is delivered is known as delivery head. This is denoted by 'h_d'.

3. Static Head (H_s). The sum of suction head and delivery head is known as static head. This is represented by 'H_s' and is written as

$$H_s = h_s + h_d. \qquad ...(19.3)$$

4. Manometric Head (H_m). The manometric head is defined as the head against which a centrifugal pump has to work. It is denoted by 'H_m'. It is given by the following expressions :

(*a*) H_m = Head imparted by the impeller to the water – Loss of head in the pump

$$= \frac{V_{w_2} u_2}{g} - \text{Loss of head in impeller and casing} \qquad ...(19.4)$$

$$= \frac{V_{w_2} u_2}{g} \quad ...\text{if loss of pump is zero} \qquad ...(19.5)$$

(*b*) H_m = Total head at outlet of the pump – Total head at the inlet of the pump

$$= \left(\frac{P_o}{\rho g} + \frac{V_o^2}{2g} + Z_o\right) - \left(\frac{p_i}{\rho g} + \frac{V_i^2}{2g} + Z_i\right) \qquad ...(19.6)$$

where $\frac{p_o}{\rho g}$ = Pressure head at outlet of the pump = h_d

$\frac{V_o^2}{2g}$ = Velocity head at outlet of the pump

= Velocity head in delivery pipe = $\frac{V_d^2}{2g}$

Z_o = Vertical height of the outlet of the pump from datum line, and

$\frac{p_i}{\rho g}, \frac{V_i^2}{2g}, Z_i$ = Corresponding values of pressure head, velocity head and datum head at the inlet of the pump,

i.e., $h_s, \frac{V_s^2}{2g}$ and Z_s respectively.

(*c*) $$H_m = h_s + h_d + h_{f_s} + h_{f_d} + \frac{V_d^2}{2g} \qquad ...(19.7)$$

where h_s = Suction head, h_d = Delivery head,

h_{f_s} = Frictional head loss in suction pipe, h_{f_d} = Frictional head loss in delivery pipe, and

V_d = Velocity of water in delivery pipe.

5. Efficiencies of a Centrifugal Pump. In case of a centrifugal pump, the power is transmitted from the shaft of the electric motor to the shaft of the pump and then to the impeller. From the impeller, the power is given to the water. Thus power is decreasing from the shaft of the pump to the impeller and then to the water. The following are the important efficiencies of a centrifugal pump :

(*a*) Manometric efficiency, η_{man} (*b*) Mechanical efficiency, η_m and

(*c*) Overall efficiency, η_o.

(*a*) **Manometric Efficiency (η_{man}).** The ratio of the manometric head to the head imparted by the impeller to the water is known as manometric efficiency. Mathematically, it is written as

$$\eta_{man} = \frac{\text{Manometric head}}{\text{Head imparted by impeller to water}}$$

$$= \frac{H_m}{\left(\frac{V_{w_2} u_2}{g}\right)} = \frac{gH_m}{V_{w_2} u_2} \qquad ...(19.8)$$

The power at the impeller of the pump is more than the power given to the water at outlet of the pump. The ratio of the power given to water at outlet of the pump to the power available at the impeller, is known as manometric efficiency.

The power given to water at outlet of the pump = $\frac{WH_m}{1000}$ kW

The power at the impeller $= \frac{\text{Work done by impeller per second}}{1000}$ kW

$$= \frac{W}{g} \times \frac{V_{w_2} \times u_2}{1000} \text{kW}$$

$$\eta_{man} = \frac{\frac{W \times H_m}{1000}}{\frac{W}{g} \times \frac{V_{w_2} \times u_2}{1000}} = \frac{g \times H_m}{V_{w_2} \times u_2}.$$

(*b*) **Mechanical Efficiency (η_m).** The power at the shaft of the centrifugal pump is more than the power available at the impeller of the pump. The ratio of the power available at the impeller to the power at the shaft of the centrifugal pump is known as mechanical efficiency. It is written as

$$\eta_m = \frac{\text{Power at the impeller}}{\text{Power at the shaft}}$$

The power at the impeller in kW $= \frac{\text{Work done by impeller per second}}{1000}$

$$= \frac{W}{g} \times \frac{V_{w_2} u_2}{1000} \qquad \text{[Using equation (19.2)]}$$

$$\eta_m = \frac{\frac{W}{g}\left(\frac{V_{w_2} u_2}{1000}\right)}{\text{S.P.}} \qquad ...(19.9)$$

where S.P. = Shaft power.

(*c*) **Overall Efficiency (η_o).** It is defined as ratio of power output of the pump to the power input to the pump. The power output of the pump in kW

$$= \frac{\text{Weight of water lifted} \times H_m}{1000} = \frac{WH_m}{1000}$$

Power input to the pump = Power supplied by the electric motor

= S.P. of the pump.

$\therefore$ $$\eta_o = \frac{\left(\frac{WH_m}{1000}\right)}{\text{S.P.}} \qquad ...(19.10)$$

Also $$\eta_o = \eta_{man} \times \eta_m. \qquad ...(19.11)$$

Problem 19.1 *The internal and external diameters of the impeller of a centrifugal pump are 200 mm and 400 mm respectively. The pump is running at 1200 r.p.m. The vane angles of the impeller at inlet and outlet are 20° and 30° respectively. The water enters the impeller radially and velocity of flow is constant. Determine the work done by the impeller per unit weight of water.*

Solution. Given :

Internal diameter of impeller, $D_1 = 200$ mm $= 0.20$ m

External diameter of impeller, $D_2 = 400$ mm $= 0.40$ m

Speed, $N = 1200$ r.p.m.

Vane angle at inlet, $\theta = 20°$

Vane angle at outlet, $\phi = 30°$

Water enters radially* means, $\alpha = 90°$ and $V_{w_1} = 0$

Velocity of flow, $V_{f_1} = V_{f_2}$

Tangential velocity of impeller at inlet and outlet are,

$$u_1 = \frac{\pi D_1 N}{60} = \frac{\pi \times 0.20 \times 1200}{60} = 12.56 \text{ m/s}$$

and $$u_2 = \frac{\pi D_2 N}{60} = \frac{\pi \times 0.4 \times 1200}{60} = 25.13 \text{ m/s}.$$

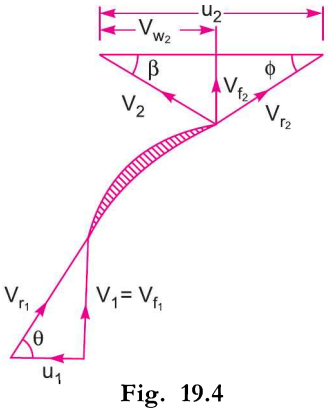

Fig. 19.4

From inlet velocity triangle, $\tan\theta = \frac{V_{f_1}}{u_1} = \frac{V_{f_1}}{12.56}$

$\therefore \quad V_{f_1} = 12.56 \tan\theta = 12.56 \times \tan 20° = 4.57$ m/s

$\therefore \quad V_{f_2} = V_{f_1} = 4.57$ m/s.

From outlet velocity triangle, $\tan\phi = \frac{V_{f_2}}{u_2 - V_{w_2}} = \frac{4.57}{25.13 - V_{w_2}}$

or $$25.13 - V_{w_2} = \frac{4.57}{\tan\phi} = \frac{4.57}{\tan 30°} = 7.915$$

$\therefore \quad V_{w_2} = 25.13 - 7.915 = 17.215$ m/s.

The work done by impeller per kg of water per second is given by equation (19.1) as

$$= \frac{1}{g} V_{w_2} u_2 = \frac{17.215 \times 25.13}{9.81} = \mathbf{44.1 \text{ Nm/N. Ans.}}$$

Problem 19.2 *A centrifugal pump is to discharge 0.118 m^3/s at a speed of 1450 r.p.m. against a head of 25 m. The impeller diameter is 250 mm, its width at outlet is 50 mm and manometric efficiency is 75%. Determine the vane angle at the outer periphery of the impeller.*

Solution. Given :

Discharge, $Q = 0.118$ m^3/s

Speed, $N = 1450$ r.p.m.

Head, $H_m = 25$ m

Diameter at outlet, $D_2 = 250$ mm $= 0.25$ m

Width at outlet, $B_2 = 50$ mm $= 0.05$ m

Manometric efficiency, $\eta_{man} = 75\% = 0.75$.

Let vane angle at outlet $= \phi$

Tangential velocity of impeller at outlet,

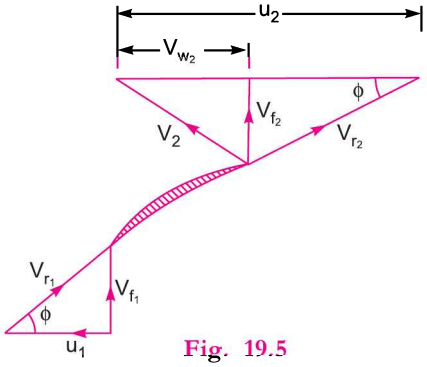

Fig. 19.5

* If in the problem, this condition is not given even then the water is assumed to be entering radially unless stated otherwise

$$u_2 = \frac{\pi D_2 N}{60} = \frac{\pi \times 0.25 \times 1450}{60} = 18.98 \text{ m/s}$$

Discharge is given by $Q = \pi D_2 B_2 \times V_{f_2}$

$$\therefore \quad V_{f_2} = \frac{Q}{\pi D_2 B_2} = \frac{0.118}{\pi \times 0.25 \times .05} = 3.0 \text{ m/s.}$$

Using equation (19.8), $\eta_{man} = \dfrac{gH_m}{V_{w_2} u_2} = \dfrac{9.81 \times 25}{V_{w_2} \times 18.98}$

$$\therefore \quad V_{w_2} = \frac{9.81 \times 25}{\eta_{man} \times 18.98} = \frac{9.81 \times 25}{0.75 \times 18.98} = 17.23.$$

From outlet velocity triangle, we have

$$\tan \phi = \frac{V_{f_2}}{(u_2 - V_{w_2})} = \frac{3.0}{(18.98 - 17.23)} = 1.7143$$

$$\therefore \quad \phi = \tan^{-1} 1.7143 = 59.74° \text{ or } \mathbf{59° 44'. Ans.}$$

Problem 19.3 *A centrifugal pump delivers water against a net head of 14.5 metres and a design speed of 1000 r.p.m. The vanes are curved back to an angle of 30° with the periphery. The impeller diameter is 300 mm and outlet width is 50 mm. Determine the discharge of the pump if manometric efficiency is 95%.*

Solution. Given :

Net head, $H_m = 14.5$ m

Speed, $N = 1000$ r.p.m.

Vane angle at outlet, $\phi = 30°$

Impeller diameter means the diameter of the impeller at outlet

$\therefore$ Diameter, $D_2 = 300$ mm $= 0.30$ m

Outlet width, $B_2 = 50$ mm $= 0.05$ m

Manometric efficiency, $\eta_{man} = 95\% = 0.95$

Tangential velocity of impeller at outlet,

$$u_2 = \frac{\pi D_2 N}{60} = \frac{\pi \times 0.30 \times 1000}{60} = 15.70 \text{ m/s.}$$

Now using equation (19.8), $\eta_{man} = \dfrac{gH_m}{V_{w_2} \times u_2}$

$$\therefore \quad 0.95 = \frac{9.81 \times 14.5}{V_{w_2} \times 15.70}$$

$$\therefore \quad V_{w_2} = \frac{0.95 \times 14.5}{0.95 \times 15.70} = 9.54 \text{ m/s.}$$

Refer to Fig. 19.5. From outlet velocity triangle, we have

$$\tan \phi = \frac{V_{f_2}}{(u_2 - V_{w_2})} \text{ or } \tan 30° = \frac{V_{f_2}}{(15.70 - 9.54)} = \frac{V_{f_2}}{6.16}$$

$$\therefore \quad V_{f_2} = 6.16 \times \tan 30° = 3.556 \text{ m/s.}$$

$\therefore$ Discharge, $Q = \pi D_2 B_2 \times V_{f_2}$

$= \pi \times 0.30 \times 0.05 \times 3.556 \text{ m}^3/\text{s} = \mathbf{0.1675 \text{ m}^3/\text{s}}$. **Ans.**

Problem 19.4 *A centrifugal pump having outer diameter equal to two times the inner diameter and running at 1000 r.p.m. works against a total head of 40 m. The velocity of flow through the impeller is constant and equal to 2.5 m/s. The vanes are set back at an angle of 40° at outlet. If the outer diameter of the impeller is 500 mm and width at outlet is 50 mm, determine* :

(*i*) *Vane angle at inlet,* (*ii*) *Work done by impeller on water per second, and*

(*iii*) *Manometric efficiency.*

Solution. Given :

Speed, $N = 1000$ r.p.m.

Head, $H_m = 40$ m

Velocity of flow, $V_{f_1} = V_{f_2} = 2.5$ m/s

Vane angle at outlet, $\phi = 40°$

Outer dia. of impeller, $D_2 = 500$ mm $= 0.50$ m

Inner dia. of impeller, $D_1 = \frac{D_2}{2} = \frac{0.50}{2} = 0.25$ m

Width at outlet, $B_2 = 50$ mm $= 0.05$ m

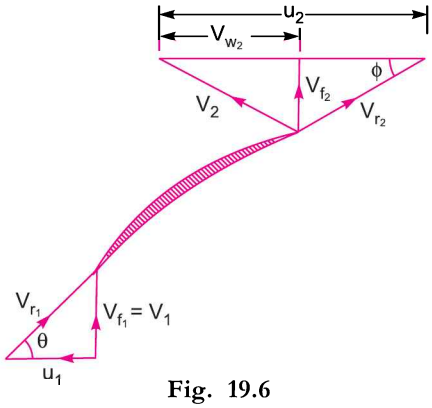

Fig. 19.6

Tangential velocity of impeller at inlet and outlet are

$$u_1 = \frac{\pi D_1 N}{60} = \frac{\pi \times 0.25 \times 1000}{60} = 13.09 \text{ m/s}$$

and $$u_2 = \frac{\pi D_2 N}{60} = \frac{\pi \times 0.50 \times 1000}{60} = 26.18 \text{ m/s.}$$

Discharge is given by, $Q = \pi D_2 B_2 \times V_{f_2} = \pi \times 0.50 \times .05 \times 2.5 = 0.1963 \text{ m}^3/\text{s}$.

(*i*) **Vane angle at inlet** (θ).

From inlet velocity triangle $\tan \theta = \frac{V_{f_1}}{u_1} = \frac{2.5}{13.09} = 0.191$

$\therefore$ $\theta = \tan^{-1} .191 = 10.81°$ or **10° 48′. Ans.**

(*ii*) **Work done by impeller on water per second** is given by equation (19.2) as

$$= \frac{W}{g} \times V_{w_2} u_2 = \frac{\rho \times g \times Q}{g} \times V_{w_2} \times u_2$$

$$= \frac{1000 \times 9.81 \times 0.1963}{9.81} \times V_{w_2} \times 26.18 \qquad \ldots(i)$$

But from outlet velocity triangle, we have

$$\tan \phi = \frac{V_{f_2}}{u_2 - V_{w_2}} = \frac{2.5}{(26.18 - V_{w_2})}$$

$\therefore$ $$26.18 - V_{w_2} = \frac{2.5}{\tan \phi} = \frac{2.5}{\tan 40°} = 2.979$$

$\therefore$ $$V_{w_2} = 26.18 - 2.979 = 23.2 \text{ m/s.}$$

Substituting this value of V_{w_2} in equation (*i*), we get the work done by impeller as

$$= \frac{1000 \times 9.81 \times 0.1963}{9.81} \times 23.2 \times 26.18$$

$$= \mathbf{119227.9 \text{ Nm/s. Ans.}}$$

(*iii*) **Manometric efficiency (η_{man}).** Using equation (19.8), we have

$$\eta_{man} = \frac{gH_m}{V_{w_2} u_2} = \frac{9.81 \times 40}{23.2 \times 26.18} = 0.646 = \mathbf{64.4\%}. \textbf{ Ans.}$$

Problem 19.5 *A centrifugal pump discharges 0.15 m^3/s of water against a head of 12.5 m, the speed of the impeller being 600 r.p.m. The outer and inner diameters of impeller are 500 mm and 250 mm respectively and the vanes are bent back at 35° to the tangent at exit. If the area of flow remains 0.07 m^2 from inlet to outlet, calculate :*

(i) Manometric efficiency of pump, (ii) Vane angle at inlet, and

(iii) Loss of head at inlet to impeller when the discharge is reduced by 40% without changing the speed.

Solution. Given :

Discharge, $Q = 0.15$ m^3/s

Head, $H_m = 12.5$ m

Speed, $N = 600$ r.p.m.

Outer dia., $D_2 = 500$ mm $= 0.50$ m

Inner dia., $D_1 = 250$ mm $= 0.25$ m

Vane angle at outlet, $\phi = 35°$

Area of flow, $= 0.07$ m^2

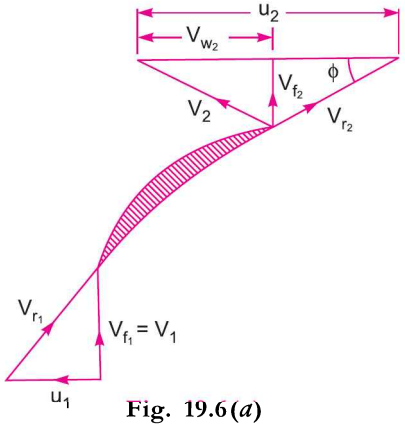

Fig. 19.6(*a*)

As area of flow is constant from inlet to outlet, then velocity of flow will be constant from inlet to outlet.

Discharge = Area of flow × Velocity of flow

or $0.15 = 0.07 \times$ Velocity of flow

$$\therefore \quad \text{Velocity of flow} = \frac{0.15}{0.07} = 2.14 \text{ m/s.}$$

$$\therefore \quad V_{f_1} = V_{f_2} = 2.14 \text{ m/s.}$$

Tangential velocity of impeller at inlet and outlet are

$$u_1 = \frac{\pi D_1 N}{60} = \frac{\pi \times 0.25 \times 600}{60} = 7.85 \text{ m/s}$$

and

$$u_2 = \frac{\pi D_2 N}{60} = \frac{\pi \times 0.50 \times 600}{60} = 15.70 \text{ m/s}$$

From outlet velocity triangle, $V_{w_2} = u_2 - \frac{V_{f_2}}{\tan \phi} = 15.70 - \frac{2.14}{\tan 35°} = 12.64$ m/s

(*i*) *Manometric efficiency of the pump*

Using equation (19.8), we have $\eta_{man} = \frac{g \times H_m}{V_{w_2} \times u_2} = \frac{9.81 \times 12.5}{12.64 \times 15.7} = 0.618$ or **61.8%. Ans.**

(*ii*) *Vane angle at inlet* (θ)

From inlet velocity triangle, $\tan \theta = \frac{V_{f_1}}{u_1} = \frac{2.14}{7.85} = 0.272$

$$\therefore \quad \theta = \tan^{-1} 0.272 = \mathbf{15° 12'}. \textbf{ Ans.}$$

(*iii*) *Loss of head at inlet to impeller when discharge is reduced by 40% without changing the speed.*

When there is an increase or decrease in the discharge from the normal discharge, a loss of head occurs at entry due to shock. In this case, discharge is reduced by 40%. Hence the new discharge is given by,

$$Q^* = 0.6 \times Q$$

where $Q = 0.15$ m^3/s

As area of flow is constant, hence new velocity of flow ($V_{f_1}{}^*$) will be given by,

$$V_{f_1}{}^* = \frac{Q^*}{\text{Area of flow}}$$

$$= \frac{0.6 \times Q}{0.07} = \frac{0.6 \times 0.15}{0.07} = 1.284 \text{ m/s.}$$

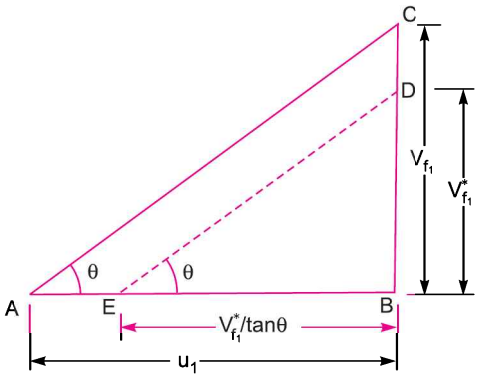

Fig. 19.6 (*b*)

Fig. 19.6 (*b*) shows the velocity triangle at inlet corresponding to normal discharge and reduced discharge. *ABC* is the velocity triangle due to normal discharge. Triangle *BDE* is corresponding to reduced discharge *BD* = 1.284 m/s and *DE* is parallel to *AC*.

The blade angle θ at inlet cannot change and hence *DE* will be parallel to *AC*.

There will be a sudden change in the tangential velocity from *AB* to *BE*. Hence due to this shock, there will be a loss of head at inlet.

$$\therefore \quad \text{Head lost at inlet} = \frac{(\text{change in tangential velocity at inlet})^2}{2g}$$

$$= \frac{(AB - BE)^2}{2g} = \frac{\left(u_1 - \dfrac{V_{f_1}^*}{\tan\theta}\right)^2}{2g} = \frac{\left(7.85 - \dfrac{1.284}{\tan 15.2°}\right)^2}{2 \times 9.81} = \mathbf{0.5 \text{ m. Ans.}}$$

Problem 19.6 *The outer diameter of an impeller of a centrifugal pump is 400 mm and outlet width is 50 mm. The pump is running at 800 r.p.m. and is working against a total head of 15 m. The vanes angle at outlet is 40° and manometric efficiency is 75%. Determine :*

(i) velocity of flow at outlet, (ii) velocity of water leaving the vane,

(iii) angle made by the absolute velocity at outlet with the direction of motion at outlet, and

(iv) discharge.

Solution. Given :

Outer diameter, $D_2 = 400$ mm$= 0.4$ m

Width at outlet, $B_2 = 50$ mm $= 0.05$ m

Speed, $N = 800$ r.p.m.

Head, $H_m = 15$ m

Vane angle at outlet, $\phi = 40°$

Manometric efficiency, $\eta_{man} = 75\% = 0.75$

Tangential velocity of impeller at outlet,

$$u_2 = \frac{\pi D_2 N}{60} = \frac{\pi \times 0.4 \times 800}{60} = 16.75 \text{ m/s.}$$

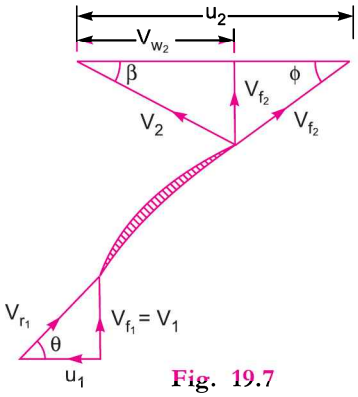

Fig. 19.7

Using equation (19.8), $\eta_{man} = \dfrac{gH_m}{V_{w_2}\, u_2}$

$$0.75 = \frac{9.81 \times 15}{V_{w_2} \times 16.75}$$

$$\therefore \quad V_{w_2} = \frac{9.81 \times 15}{0.75 \times 16.75} = 11.71 \text{ m/s.}$$

From the outlet velocity triangle, we have

$$\tan \phi = \frac{V_{f_2}}{u_2 - V_{w_2}} = \frac{V_{f_2}}{(16.75 - 11.71)} = \frac{V_{f_2}}{5.04}$$

(*i*) $\therefore \quad V_{f_2} = 5.04 \tan \phi = 5.04 \times \tan 40° =$ **4.23 m/s. Ans.**

(*ii*) **Velocity of water leaving the vane** (V_2).

$$V_2 = \sqrt{V_{f_2}^2 + V_{w_2}^2} = \sqrt{4.23^2 + 11.71^2}$$

$$= \sqrt{17.89 + 137.12} = \textbf{12.45 m/s. Ans.}$$

(*iii*) **Angle made by absolute velocity at outlet** (β),

$$\tan \beta = \frac{V_{f_2}}{V_{w_2}} = \frac{4.23}{11.71} = 0.36$$

$$\therefore \quad \beta = \tan^{-1} 0.36 = 19.80° \text{ or } \textbf{19° 48′. Ans.}$$

(*iv*) **Discharge** through pump is given by,

$$Q = \pi D_2 B_2 \times V_{f_2} = \pi \times 0.4 \times 0.05 \times 4.23 = \textbf{0.265 m}^3\textbf{/s. Ans.}$$

Problem 19.7 *A centrifugal pump is running at 1000 r.p.m. The outlet vane angle of the impeller is 45° and velocity of flow at outlet is 2.5 m/s. The discharge through the pump is 200 litres/s when the pump is working against a total head of 20 m. If the manometric efficiency of the pump is 80%, determine :*

(*i*) *the diameter* of the impeller, and* (*ii*) *the width of the impeller at outlet.*

Solution. Given :

Speed, $N = 1000$ r.p.m.

Outlet vane angle, $\phi = 45°$

Velocity of flow at outlet, $V_{f_2} = 2.5$ m/s

Discharge, $Q = 200$ litres/s $= 0.2$ m^2/s

Head, $H_m = 20$ m

Manometric efficiency, $\eta_{man} = 80\% = 0.80$

From outlet velocity triangle, we have

$$\tan \phi = \frac{V_{f_2}}{u_2 - V_{w_2}}$$

or $$u_2 - V_{w_2} = \frac{V_{f_2}}{\tan \phi} = \frac{2.5}{\tan 45} = 2.5$$

$$\therefore \quad V_{w_2} = (u_2 - 2.5) \qquad \ldots(i)$$

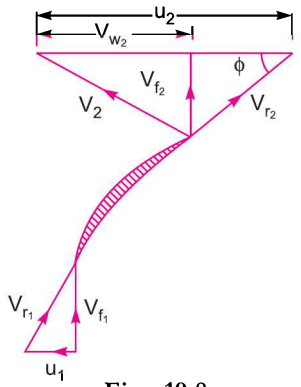

Fig. 19.8

* Diameter of impeller means the outside diameter.

Using equation (19.8), $\eta_{man} = \dfrac{gH_m}{V_{w_2} u_2}$

$$0.80 = \frac{9.81 \times 20}{V_{w_2} u_2}$$

$$\therefore \quad V_{w_2} u_2 = \frac{9.81 \times 20}{0.80} = 245.25 \qquad ...(ii)$$

Substituting the value of V_{w_2} from equation (i) in (ii), we get

$$(u_2 - 2.5)u_2 = 245.25$$

$$u_2^2 - 2.5u_2 - 245.25 = 0$$

which is a quadratic equation in u_2 and its solution is

$$u_2 = \frac{2.5 \pm \sqrt{(2.5)^2 + 4 \times 245.25}}{2} = \frac{2.5 + \sqrt{6.25 + 981}}{2}$$

$$= \frac{2.5 \pm 31.42}{2} = 16.96 \text{ or } -14.46$$

$$\therefore \quad u_2 = 16.96 \qquad (\because \text{ –ve value is not possible})$$

(i) *Diameter of impeller* (D_2).

Using, $u_2 = \dfrac{\pi D_2 N}{60}$

$$\therefore \quad 16.96 = \frac{\pi D_2 N}{60} = \frac{\pi \times D_2 \times 1000}{60}$$

$$\therefore \quad D_2 = \frac{16.96 \times 60}{\pi \times 1000} = 0.324 \text{ m} = \textbf{324 mm. Ans.}$$

(ii) *Width of impeller at outlet* (B_2).

Discharge, $Q = \pi D_2 B_2 V_{f_2}$

$$0.2 = \pi \times .324 \times B_2 \times 2.5$$

$$\therefore \quad B_2 = \frac{0.2}{\pi \times .324 \times 2.5} = 0.0786 \text{ m} = \textbf{78.6 mm. Ans.}$$

Problem 19.7 (A) *A centrifugal pump has the following dimensions : inlet radius = 80 mm ; outlet radius = 160 mm ; width of impeller at the inlet = 50 mm ;* $\beta_1 = 0.45$ *radians ;* $\beta_2 = 0.25$ *radians ; width of impeller at outlet = 50 mm.*

Assuming shockless entry determine the discharge and the head developed by the pump when the impeller rotates at 90 radians/second.

Solution. Given :

Inlet radius, $R_1 = 80 \text{ mm} = 0.08 \text{ m}$

Outlet radius $R_2 = 160 \text{ mm} = 0.16 \text{ m}$

Width at inlet, $B_1 = 50 \text{ mm} = 0.05 \text{ m}$

Width at outlet, $B_2 = 50 \text{ mm} = 0.05 \text{ m}$

Angles, $\beta_1 = 0.45$ radians and $\beta_2 = 0.25$ radians.

Here β_1 is the vane angle at inlet and β_2 is the vane angle at outlet.

∴ Vane angle at inlet, $\theta = \beta_1 = 0.45$ radians

Vane angle at outlet, $\phi = \beta_2 = 0.25$ radians.

Angular velocity, $\omega = 90$ rad/s

Find :

(*i*) discharge, and (*ii*) head developed.

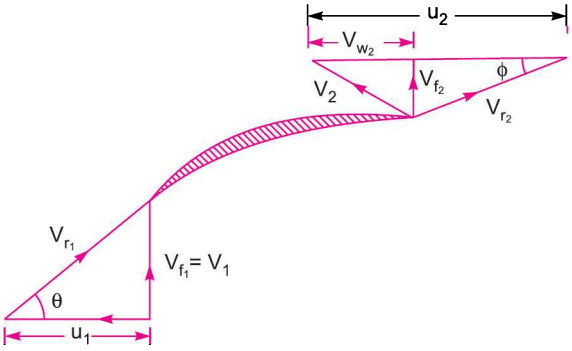

Fig. 19.8 (*a*)

Now tangential velocity of impeller at inlet and outlet are,

$$u_1 = \frac{\pi D_1 \times N}{60} = \frac{2\pi N}{60} \times \frac{D_1}{2} = \omega \times R_1 = 90 \times 0.08 = 7.2 \text{ m/s}$$

and $$u_2 = \omega \times R_2 = 90 \times 0.16 = 14.4 \text{ m/s}$$

From inlet velocity triangle, $\tan\theta = \dfrac{V_{f_1}}{u_1}$

∴ $$V_{f_1} = u_1 \times \tan\theta = 7.2 \times \tan(0.45 \text{ rad}) = 7.2 \times 0.483 = 3.478 \text{ m/s}$$

(*i*) *Discharge* (Q)

Discharge is given by, $Q = \pi D_1 \times B_1 \times V_{f_1} = \pi \times (2R_1) \times B_1 \times V_{f_1}$

$= \pi \times 2 \times 0.08 \times 0.05 \times 3.478 \text{ m}^3/\text{s} =$ **0.0874 m^3/s. Ans.**

(*ii*) *Head developed* (H_m)

For the shockless entry, the losses of the pump will be zero. Hence, the head developed (H_m) will be given by equation (19.5).

∴ $$H_m = \frac{V_{w_2} \times u_2}{g} \quad \ldots(i)$$

where from outlet velocity triangle, $V_{w_2} = u_2 - V_{f_2} \times \cot\phi$

The value of V_{f_2} is obtained from $Q = \pi D_2 \times B_2 \times V_{f_2}$

or $$0.0874 = \pi \times (2R_2) \times B_2 \times V_{f_2}$$

$$= \pi \times (2 \times 0.16) \times 0.05 \times V_{f_2}$$

∴ $$V_{f_2} = \frac{0.0874}{\pi \times 2 \times 0.16 \times 0.05} = 1.7387 \text{ m/s}$$

∴ $$V_{w_2} = u_2 - V_{f_2} \times \cot\phi$$

$= 14.4 - 1.7387 \times \cot (0.25 \text{ radians})$

$= 14.4 - 1.7387 \times 3.9163 = 14.4 - 6.809 = 7.591$ m/s

Substituting this value in equation (*i*) above, we get

$$H_m = \frac{V_{w_2} \times u_2}{g} = \frac{7.591 \times 14.4}{9.81} = \textbf{11.142 m. Ans.}$$

Problem 19.8 *The internal and external diameter of an impeller of a centrifugal pump which is running at 1000 r.p.m., are 200 mm and 400 mm respectively. The discharge through pump is 0.04 m^3/s and velocity of flow is constant and equal to 2.0 m/s. The diameters of the suction and delivery pipes are 150 mm and 100 mm respectively and suction and delivery heads are 6 m (abs.) and 30 m (abs.) of water respectively. If the outlet vane angle is 45° and power required to drive the pump is 16.186 kW, determine :*

(i) Vane angle of the impeller at inlet, (ii) The overall efficiency of the pump, and

(iii) Manometric efficiency of the pump.

Solution. Given :

Speed,	$N = 1000$ r.p.m.
Internal dia.,	$D_1 = 200$ mm $= 0.2$ m
External dia.,	$D_2 = 400$ mm $= 0.4$ m
Discharge,	$Q = 0.04$ m^3/s
Velocity of flow,	$V_{f_1} = V_{f_2} = 2.0$ m/s
Dia. of suction pipe,	$D_s = 150$ mm $= 0.15$ m
Dia. of delivery pipe,	$D_d = 100$ mm $= 0.10$ m
Suction head,	$h_s = 6$ m (abs.)
Delivery head,	$h_d = 30$ m (abs.)
Outlet vane angle,	$\phi = 45°$
Power required to drive the pump,	$P = 16.186$/ kW

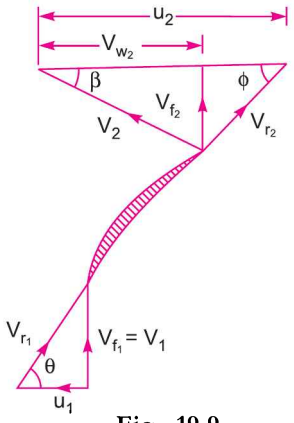

Fig. 19.9

(*i*) Vane angle of the impeller at inlet (θ).

From inlet velocity, we have $\tan \theta = \frac{V_{f_1}}{u_1} = \frac{2.0}{u_1}$, where $u_1 = \frac{\pi D_1 N}{60} = \frac{\pi \times 0.2 \times 1000}{60} = 10.47$ m/s

$$\therefore \quad \tan \theta = \frac{2.0}{10.47} = 0.191 \text{ or } \theta = \tan^{-1} .191 = \textbf{10° 48′. Ans.}$$

(*ii*) Overall efficiency of the pump (η_o).

Using equation (19.10), we have $\eta_o = \dfrac{\left(\frac{WH_m}{1000}\right)}{\text{S.P.}}$

where S.P. = Power required to drive the pump and equal to P here.

$$\eta_o = \frac{\left(\frac{\rho \times g \times Q \times H_m}{1000}\right)}{P} = \frac{\rho g \times Q \times H_m}{1000 \times P}$$

$$= \frac{1000 \times 9.81 \times .04 \times H_m}{1000 \times 16.186} = 0.02424 \, H_m \qquad \ldots(i)$$

Now H_m is given by equation (19.6) as

$$H_m = \left(\frac{p_o}{\rho g} + \frac{V_o^2}{2g} + Z_o\right) - \left(\frac{p_i}{\rho g} + \frac{V_i^2}{2g} + Z_i\right) \quad ...(ii)$$

where $\frac{p_o}{\rho g}$ = Pressure head at outlet of pump = h_d = 30 m

$\frac{V_o^2}{2g}$ = Velocity head at outlet of pump = $\frac{V_d^2}{2g}$

$\frac{p_i}{\rho g}$ = Pressure head at inlet of pump = h_s = 6 m

$\frac{V_i^2}{2g}$ = Velocity head at inlet of pump = $\frac{V_s^2}{2g}$

Z_o and Z_i = Vertical height at outlet and inlet of the pump from datum line.

If $Z_o = Z_i$ then equation(*ii*) becomes as

$$H_m = \left(30 + \frac{V_d^2}{2g}\right) - \left(6 + \frac{V_s^2}{2g}\right) \quad ...(iii)$$

Now $$V_d = \frac{\text{Discharge}}{\text{Area of delivery pipe}} = \frac{0.04}{\frac{\pi}{4}(D_d)^2} = \frac{.04}{\frac{\pi}{4}\times .1^2} = 5.09 \text{ m/s}$$

And $$V_s = \frac{.04}{\text{Area of suction pipe}} = \frac{.04}{\frac{\pi}{4}D_s^2} = \frac{.04}{\frac{\pi}{4}\times .15^2} = 2.26 \text{ m/s.}$$

Substituting these values in equation (*iii*), we get

$$H_m = \left(30 + \frac{5.09^2}{2\times 9.81}\right) - \left(6 + \frac{2.26^2}{2\times 9.81}\right)$$

$$= (30 + 1.32) - (6 + .26) = 31.32 - 6.26 = 25.06 \text{ m.}$$

Substituting the value of 'H_m' in equation (*i*), we get

$$\eta_o = .02424 \times 25.06 = 0.6074 = \mathbf{60.74\%. \text{ Ans.}}$$

(*iii*) **Manometric efficiency of the pump (η_{man}).**

Tangential velocity at outlet is given by

$$u_2 = \frac{\pi D_2 \times N}{60} = \frac{\pi \times 0.4 \times 1000}{60} = 20.94 \text{ m/s.}$$

From outlet velocity triangle, we have

$$\tan \phi = \frac{V_{f_2}}{u_2 - V_{w_2}} = \frac{2.0}{20.94 - V_{w_2}}$$

$$\therefore \quad 20.94 - V_{w_2} = \frac{2.0}{\tan \phi} = \frac{2.0}{\tan 45} = 2.0$$

$$\therefore \quad V_{w_2} = 20.94 - 2.0 = 18.94.$$

Using equation (19.8), $$\eta_{man} = \frac{gH_m}{V_{w_2} u_2} = \frac{9.81 \times 25.06}{18.94 \times 20.94} = 0.6198 = \mathbf{61.98\%. \text{ Ans.}}$$

Problem 19.9 *Find the power required to drive a centrifugal pump which delivers 0.04 m^3/s of water to a height of 20 m through a 15 cm diameter pipe and 100 m long. The overall efficiency of the pump is 70% and co-efficient of friction 'f' = 0.15 in the formula* $h_f = \dfrac{4fLV^2}{d \times 2g}$.

Solution. Given :

Discharge, $Q = 0.04\ m^3/s$

Height, $H_s = h_s + h_d = 20$ m

Dia. of pipe, $D_s = D_d = 15$ cm $= 0.15$ m

Length, $L_s + L_d = L = 100$ m

Overall efficiency, $\eta_o = 70\% = 0.70$

Co-efficient of friction, $f = .015$

Velocity of water in pipe, $V_s = V_d = V = \dfrac{\text{Discharge}}{\text{Area of pipe}} = \dfrac{0.04}{\frac{\pi}{4}(.15)^2} = 2.26$ m/s.

Frictional head loss in pipe,

$$(h_{f_s} + h_{f_d}) = \frac{4fLV^2}{d \times 2g} = \frac{4 \times .015 \times 100 \times 2.26^2}{.15 \times 2 \times 9.81} = 10.41 \text{ m.}$$

Using equation (19.7), we get manometric head as

$$H_m = (h_s + h_d) + (h_{f_s} + h_{f_d}) + \frac{V_d^2}{2g}$$

$$= 20 + 10.41 + \frac{2.26^2}{2 \times 9.81} \qquad (\because \quad h_s + h_d = H_s = 20 \text{ m})$$

$$= 30.41 + 0.26 = 30.67 \text{ m.}$$

Overall efficiency is given by equation (19.10) as

$$\eta_o = \frac{\left(\frac{WH_m}{1000}\right)}{\text{S.P.}} = \frac{\rho g \times Q \times H_m}{1000 \times \text{S.P.}}$$

$$\therefore \qquad \text{S.P.} = \frac{\rho g \times Q \times H_m}{1000 \times \eta_o} = \frac{1000 \times 9.81 \times .04 \times 30.67}{1000 \times 0.70} = \mathbf{17.19\ kW.\ Ans.}$$

S.P. is the power required to drive the centrifugal pump.

Problem 19.10 *Show that the pressure rise in the impeller of a centrifugal pump when frictional and other losses in the impeller are neglected is given by*

$$\frac{1}{2g}\left[V_{f_1}^2 + u_2^2 - V_{f_2}^2\ cosec^2\ \phi\right]$$

where V_{f_1} *and* V_{f_2} *are velocity of flow at inlet and outlet,*

u_2 *= tangential velocity of impeller at outlet, and* ϕ *= vane angle at outlet.*

Solution. Let suffix 1 represents the values at the inlet and suffix 2 represents the values at the outlet of the impeller.

Applying Bernoulli's equation at the inlet and outlet of the impeller and neglecting losses from inlet to outlet,

Total energy at inlet = Total energy at outlet – Work done by impeller on water

$$\frac{p_1}{\rho g}+\frac{V_1^2}{2g}+Z_1=\left(\frac{p_2}{\rho g}+\frac{V_2^2}{2g}+Z_2\right)-\text{Work done by impeller on water per kg of water}$$

$$=\frac{p_2}{\rho g}+\frac{V_2^2}{2g}+Z_2-\frac{V_{w_2}u_2}{g} \qquad \text{(taking flow radial at inlet)}$$

If inlet and outlet of the impeller are at the same height,

$$\frac{p_1}{\rho g}+\frac{V_1^2}{2g}=\frac{p_2}{\rho g}+\frac{V_2^2}{2g}-\frac{V_{w_2}u_2}{g} \qquad (\because \quad Z_1=Z_2)$$

$$\therefore \qquad \left(\frac{p_2}{\rho g}-\frac{p_1}{\rho g}\right)=\frac{V_1^2}{2g}-\frac{V_2^2}{2g}+\frac{V_{w_2}u_2}{g}$$

But $\frac{p_2}{\rho g}-\frac{p_1}{\rho g}$ = Pressure rise in impeller

$$\therefore \quad \text{Pressure rise in impeller} = \frac{V_1^2}{2g}-\frac{V_2^2}{2g}+\frac{V_{w_2}u_2}{g} \qquad ...(i)$$

From Fig. 19.9, we have

From inlet velocity triangle, $V_1 = V_{f_1}$ ...(*ii*)

From outlet velocity triangle, $\tan\phi=\frac{V_{f_2}}{(u_2-V_{w_2})}$ or $u_2-V_{w_2}=\frac{V_{f_2}}{\tan\phi}$

$$\therefore \qquad V_{w_2}=u_2-\frac{V_{f_2}}{\tan\phi}=u_2-V_{f_2}\cot\phi \qquad ...(iii)$$

Also
$$\begin{aligned}V_2^2 &= V_{f_2}^2+V_{w_2}^2=V_{f_2}^2+(u_2-V_{f_2}\cot\phi)^2\\ &=V_{f_2}^2+(u_2^2+V_{f_2}^2\cot^2\phi-2u_2V_{f_2}\cot\phi)\\ &=V_{f_2}^2+V_{f_2}^2\cot^2\phi+u_2^2-2u_2V_{f_2}\cot\phi\\ &=V_{f_2}^2(1+\cot^2\phi)+u_2^2-2u_2V_{f_2}\cot\phi\\ &=V_{f_2}^2\operatorname{cosec}^2\phi+u_2^2-2u_2V_{f_2}\cot\phi \qquad (\because 1+\cot^2\phi=\operatorname{cosec}^2\phi) \quad ...(iv)\end{aligned}$$

Substituting the values of V_1, V_{w_2} and V_2^2 given by equations (*ii*), (*iii*) and (*iv*) in equation (*i*), we get

$$\begin{aligned}\text{Pressure rise} &= \frac{V_{f_1}^2}{2g}-\frac{1}{2g}(V_{f_2}^2\operatorname{cosec}^2\phi+u_2^2-2u_2V_{f_2}\cot\phi)+\frac{(u_2-V_{f_2}\cot\phi)\times u_2}{g}\\ &=\frac{1}{2g}[V_{f_1}^2-V_{f_2}^2\operatorname{cosec}^2\phi-u_2^2+2u_2V_{f_2}\cot\phi+2u_2^2-2u_2V_{f_2}\times\cot\phi]\\ &=\frac{1}{2g}[V_{f_1}^2-V_{f_2}^2\operatorname{cosec}^2\phi+u_2^2]\\ &=\frac{1}{2g}[V_{f_1}^2+u_2^2-V_{f_2}^2\operatorname{cosec}^2\phi]. \qquad ...(19.12)\end{aligned}$$

Problem 19.11 *Find the rise in pressure in the impeller of a centrifugal pump through which water is flowing at the rate of 0.01 m^3/s. The internal and external diameters of the impeller are 15 cm and 30 cm respectively. The widths of the impeller at inlet and outlet are 1.2 cm and 0.6 cm. The pump is running at 1500 r.p.m. The water enters the impeller radially at inlet and impeller vane angle at outlet is 45°. Neglect losses through the impeller.*

Solution. Given :

Discharge, $Q = .10\ m^3/s$

Internal dia., $D_1 = 15\ cm = 0.15\ m$

External dia., $D_2 = 30\ cm = 0.30\ m$

Width at inlet, $B_1 = 1.2\ cm = 0.012\ m$

Width at outlet, $B_2 = 0.6\ cm = 0.006\ m$

Speed, $N = 1500$ r.p.m.

Vane angle at inlet, $\phi = 45°$

Velocity of flow at outlet, $$V_{f_1} = \frac{Q}{\text{Area of flow at inlet}} = \frac{.01}{\pi D_1 B_1} = \frac{.01}{\pi \times .15 \times .012} = 1.768 \text{ m/s}$$

Velocity of flow at outlet, $$V_{f_2} = \frac{Q}{\pi D_2 B_2} = \frac{.01}{\pi \times .30 \times .006} = 1.768 \text{ m/s.}$$

Tangential velocity of impeller at outlet,

$$u_2 = \frac{\pi D_2 N}{60} = \frac{\pi \times 0.30 \times 1500}{60} = 23.56 \text{ m/s.}$$

Using equation (19.12),

$$\text{Pressure rise} = \frac{1}{2g} [V_{f_1}^2 + u_2^2 - V_{f_2}^2 \operatorname{cosec}^2 \phi]$$

$$= \frac{1}{2g} [1.768^2 + 23.56^2 - 1.768^2 \operatorname{cosec}^2 45°]$$

But $$\operatorname{cosec}^2 45° = 1 + \cot^2 45° = 1 + \frac{1}{\tan^2 45°} = 1 + 1 = 2$$

$\therefore$ Pressure rise $$= \frac{1}{2 \times 9.81} [1.768^2 + 23.56^2 - 1.768^2 \times 2.0]$$

$$= \frac{1}{2 \times 9.81} [3.1258 + 555.07 - 6.25] = \mathbf{28.13\ m.\ Ans.}$$

Problem 19.12 *Prove that the manometric head of a centrifugal pump running at speed N and giving a discharge Q may be written as :*

$$H_{mano} = AN^2 + BNQ + CQ^2$$

where A, B and C are constants.

Solution. From equation (19.4), we know that the manometric head is equal to the head imparted by the impeller to the water minus the losses of head in the impeller and casing.

$\therefore$ Manometric head $$= \frac{V_{w_2} u_2}{g} - \text{Losses of head in impeller and casing}$$

or $$H_{mano} = \frac{V_{w_2} u_2}{g} - \frac{K V_2^2}{2g} \qquad ...(i)$$

where V_2 = Absolute velocity of water at outlet of impeller and

$K\dfrac{V_2^2}{2g}$ is the part of head not converted into pressure head and is actually lost in eddies.

Now u_2 = Velocity of impeller at outlet

$$= \frac{\pi D_2 N}{60}$$
$$= K_1 N$$

where $K_1 = \dfrac{\pi D_2}{60}$ and is a constant.

From equation (19.2 *A*), we know that

$$Q = \pi D_2 B_2 \times V_{f_2}$$

$$\therefore \quad V_{f_2} = \frac{Q}{\pi D_2 B_2} = K_2 Q$$

where $K_2 = \dfrac{1}{\pi D_2 B_2}$ and is a constant for a given pump.

From Fig. 19.10, it is clear that

$$\tan \phi = \frac{V_{f_2}}{u_2 - V_{w_2}}$$

$$\therefore \quad u_2 - V_{w_2} = \frac{V_{f_2}}{\tan \phi} = V_{f_2} \cot \phi$$

or
$$V_{w_2} = u_2 - V_{f_2} \cot \phi$$
$$= u_2 - K_2 Q \cot \phi \qquad (\because\ V_{f_2} = K_2 Q)$$
$$= u_2 - K_3 Q \qquad \text{where } K_3 = K_2 \cot \phi$$
$$= K_1 N - K_3 Q \qquad (\because\ u_2 = K_1 N)$$

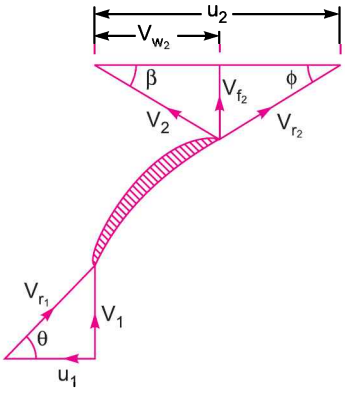

Fig. 19.10

Now from outlet velocity triangle, we know that

$$V_2^2 = V_{f_2}^2 + V_{w_2}^2$$
$$= (K_2 Q)^2 + (K_1 N - K_3 Q)^2 \qquad (\because\ V_{f_2} = K_2 Q \text{ and } V_{w_2} = K_1 N - K_3 Q)$$

Substituting the values of V_{w_2}, u_2 and V_2 in equation (*i*), we get

$$H_{mano} = \frac{(K_1 N - K_3 Q)(K_1 N)}{g} - \frac{K\left[K_2^2 Q^2 + K_1^2 N^2 + K_3^2 Q^2 - 2K_1 N \times K_3 Q\right]}{2g}$$

$$= \frac{1}{2g}\left[2(K_1^2 N^2 - K_1 K_3 NQ) - KK_2^2 Q^2 - KK_1^2 N^2 - KK_3^2\, Q^2 + 2KK_1 K_3 NQ\right]$$

$$= \frac{1}{2g}\left[N^2(2K_1^2 - KK_1^2) + NQ(2KK_1 K_3 - 2K_1 K_3) + Q^2(-KK_2^2 - KK_3^2)\right]$$

$$= AN^2 + BNQ + CQ^2$$

where $A = \dfrac{2K_1^2 - KK_1^2}{2g}$, $B = \dfrac{2KK_1 K_3 - 2K_1 K_3}{2g}$ and $C = \dfrac{-KK_2^2 - KK_3^2}{2g}$ and they are constant.

▶ 19.5 MINIMUM SPEED FOR STARTING A CENTRIFUGAL PUMP

If the pressure rise in the impeller is more than or equal to manometric head (H_m), the centrifugal pump will start delivering water. Otherwise, the pump will not discharge any water, though the impeller is rotating. When impeller is rotating, the water in contact with the impeller is also rotating. This is the case of forced vortex. In case of forced vortex, the centrifugal head or head due to pressure rise in the impeller

$$= \frac{\omega^2 r_2^2}{2g} - \frac{\omega^2 r_1^2}{2g} \qquad ...(i)$$

where ωr_2 = Tangential velocity of impeller at outlet = u_2, and
ωr_1 = Tangential velocity of impeller at inlet = u_1.

$\therefore$ Head due to pressure rise in impeller $= \frac{u_2^2}{2g} - \frac{u_1^2}{2g}$

The flow of water will commence only if

Head due to pressure rise in impeller $\geq H_m$ or $\frac{u_2^2}{2g} - \frac{u_1^2}{2g} \geq H_m$.

For minimum speed, we must have $\frac{u_2^2}{2g} - \frac{u_1^2}{2g} = H_m$ ...(19.13)

But from equation (19.8), we have $\eta_{man} = \frac{gH_m}{V_{w_2} u_2}$

$\therefore$ $H_m = \eta_{man} \times \frac{V_{w_2} u_2}{g}$.

Substituting this value of H_m in equation (19.13),

$$\frac{u_2^2}{2g} - \frac{u_1^2}{2g} = \eta_{man} \times \frac{V_{w_2} u_2}{g} \qquad ...(19.14)$$

Now $u_2 = \frac{\pi D_2 N}{60}$ and $u_1 = \frac{\pi D_1 N}{60}$.

Substituting the values of u_2 and u_1 in equation (19.14),

$$\frac{1}{2g}\left(\frac{\pi D_2 N}{60}\right)^2 - \frac{1}{2g}\left(\frac{\pi D_1 N}{60}\right)^2 = \eta_{man} \times \frac{V_{w_2} \times \pi D_2 N}{g \times 60}$$

Dividing by $\frac{\pi N}{g \times 60}$, we get $\frac{\pi N D_2^2}{120} - \frac{\pi N D_1^2}{120} = \eta_{man} \times V_{w_2} \times D_2$

or $\frac{\pi N}{120} [D_2^2 - D_1^2] = \eta_{man} \times V_{w_2} \times D_2$

$\therefore$ $N = \frac{120 \times \eta_{man} \times V_{w_2} \times D_2}{\pi \left[D_2^2 - D_1^2\right]}$ ...(19.15)

Equation (19.15) gives the minimum starting speed of the centrifugal pump.

Problem 19.13 *The diameters of an impeller of a centrifugal pump at inlet and outlet are 30 cm and 60 cm respectively. Determine the minimum starting speed of the pump if it works against a head of 30 m.*

Solution. Given :

Dia. of impeller at inlet, $D_1 = 30$ cm $= 0.30$ m

Dia. of impeller at outlet, $D_2 = 60$ cm $= 0.60$ m

Head, $H_m = 30$ cm

Let the minimum starting speed $= N$

Using equation (19.l3) for minimum speed,

$$\frac{u_2^2}{2g} - \frac{u_1^2}{2g} = H_m$$

where $u_2 = \frac{\pi \times D_2 \times N}{60} = \frac{\pi \times 0.6 \times N}{60} = 0.03141\ N$

$$u_1 = \frac{\pi \times D_1 \times N}{60} = \frac{\pi \times .3 \times N}{60} = 0.0157\ N$$

$\therefore \quad \frac{1}{2g}(0.3141\ N)^2 - \frac{1}{2g}(.0157\ N)^2 = 30$

or $(.03141\ N)^2 - (.0157\ N)^2 = 30 \times 2 \times g = 30 \times 2 \times 9.81$

or $$N^2 = \frac{30 \times 2 \times 9.81}{\left(.03141^2 - .0157^2\right)} = \frac{588.6}{.0009866 - .0002465} = 795297.9$$

$\therefore \quad N = \sqrt{795297.9} =$ **891.8 r.p.m. Ans.**

Problem 19.14 *The diameters of an impeller of a centrifugal pump at inlet and outlet are 30 cm and 60 cm respectively. The velocity of flow at outlet is 2.0 m/s and the vanes are set back at an angle of 45° at the outlet. Determine the minimum starting speed of the pump if the manometric efficiency is 70%.*

Solution. Given :

Diameter at inlet, $D_1 = 30$ cm $= 0.30$ m

Diameter at outlet, $D_2 = 60$ cm $= 0.60$ m

Velocity of flow at outlet, $V_{f_2} = 2.0$ m/s

Vane angle at outlet, $\phi = 45°$

Manometric efficiency, $\eta_{man} = 70\% = 0.70$.

Let the minimum starting speed $= N$.

From Fig. 19.9, for velocity triangle at outlet, we have

$$\tan\phi = \frac{V_{f_2}}{\left(u_2 - V_{w_2}\right)} \quad \text{or} \quad u_2 - V_{w_2} = \frac{V_{f_2}}{\tan\phi} = \frac{2.0}{\tan 45°} = 2.0$$

$\therefore \quad V_{w_2} = u_2 - 2.0$

But $$u_2 = \frac{\pi D_2 N}{60} = \frac{\pi \times 0.60 \times N}{60} = 0.03141\ \text{N}$$

$\therefore \quad V_{w_2} = (0.03141N - 2.0).$

Using equation (19.15) for minimum starting speed,

$$N = \frac{120 \times \eta_{man} \times V_{w_2} \times D_2}{\pi\left[D_2^2 - D_1^2\right]} = \frac{120 \times 0.70 \times (.03141\,N - 2.0) \times 0.6}{\pi\left[.6^2 - .3^2\right]}$$

$$= \frac{50.4(.03141\,N - 2.0)}{\pi[.36 - .09]} = 59.417\ [.03141\ N - 2.0]$$

$$= 1.866\ N - 118.834$$

or $\quad 1.866\,N - N = 118.834$ or $.886\,N = 118.834$

$\therefore \quad N = \dfrac{118.834}{0.866} =$ **137.22 r.p.m. Ans.**

Problem 19.15 *A centrifugal pump with 1.2 m diameter runs at 200 r.p.m. and pumps 1880 litres/s, the average lift being 6 m. The angle which the vanes make at exit with the tangent to the impeller is 26° and the radial velocity of flow is 2.5 m/s. Determine the manometric efficiency and the least speed to start pumping against a head of 6 m, the inner diameter of the impeller being 0.6 m.*

Solution. Given :

Dia. at outlet, $D_2 = 1.2$ m

Speed, $N = 200$ r.p.m.

Discharge, $Q = 1880$ litres/s $= 1.88$ m^3/s

Manometric head, $H_m = .6$ m

Angle of vane at outlet, $\phi = 26°$

Velocity of flow at outlet, $V_{f_2} = 2.5$ m/s

Dia. at inlet, $D_1 = 0.6$ m

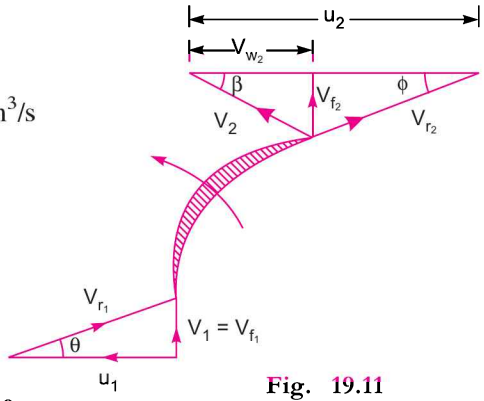

Fig. 19.11

(*i*) *Manometric efficiency* (η_{man})

Using equation (19.8), $\quad \eta_{man} = \dfrac{gH_m}{V_{w_2} \times u_2}$ $\quad ...(i)$

But $\quad u_2 = \dfrac{\pi D_2 N}{60} = \dfrac{\pi \times 1.2 \times 200}{60} = 12.56$ m/s

and $\quad \tan\phi = \dfrac{V_{f_2}}{u_2 - V_{w_2}}$ or $u_2 - V_{w_2} = \dfrac{V_{f_2}}{\tan\phi} = \dfrac{2.5}{\tan 26°} = 5.13$

$\therefore \quad V_{w_2} = u_2 - 5.13 = 12.56 - 5.13 = 7.43$ m/s.

Substituting these values in equation (*i*), we get

$$\eta_{man} = \frac{9.81 \times 6.0}{7.43 \times 12.56} = 0.63 = \mathbf{63\%}.\ \textbf{Ans.}$$

(*ii*) *Least speed to start the pump* :

Least speed to start the pump is given by equation(19.13),

$$\frac{u_2^2}{2g} - \frac{u_1^2}{2g} = H_m \qquad ...(ii)$$

where u_2 and u_1 are the tangential velocities of the vane at outlet and inlet respectively, corresponding to least speed of the pump.

But $u_2 = \omega \times r_2$ and $u_1 = \omega \times r_1$.

Substituting these values in equation (*ii*), we get

$$\frac{(\omega \times r_2)^2}{2g} - \frac{(\omega \times r_1)^2}{2g} = H_m = 6.0 \text{ or } \frac{\omega^2}{2g}\left[r_2^2 - r_1^2\right] = 6.0$$

or $$\frac{\omega^2}{2 \times 9.81}\left[0.6^2 - 0.3^2\right] = 6.0 \quad \left(\because \quad r_2 = \frac{D_2}{2} = \frac{1.2}{2} = 0.6 \text{ m and } r_1 = \frac{D_1}{2} = \frac{0.6}{2} = 0.3 \text{ m}\right)$$

$$\therefore \quad \omega^2 = \frac{6.0 \times 2.0 \times 9.81}{0.36 - .09} = 436 \quad \therefore \quad \omega = \sqrt{436} = 20.88 = \frac{2\pi N}{60}$$

$$\therefore \quad N = \frac{60 \times 20.88}{2 \times \pi} = \textbf{200 r.p.m. Ans.}$$

▶ 19.6 MULTISTAGE CENTRIFUGAL PUMPS

If a centrifugal pump consists of two or more impellers, the pump is called a multistage centrifugal pump. The impellers may be mounted on the same shaft or on different shafts. A multistage pump is having the following two important functions :

1. To produce a high head, and 2. To discharge a large quantity of liquid.

If a high head is to be developed, the impellers are connected in series (or on the same shaft) while for discharging large quantity of liquid, the impellers (or pumps) are connected in parallel.

19.6.1 Multistage Centrifugal Pumps for High Heads. For developing a high head, a number of impellers are mounted in series or on the same shaft as shown in Fig. 19.12.

The water from suction pipe enters the 1st impeller at inlet and is discharged at outlet with increased pressure. The water with increased pressure from the outlet of the 1st impeller is taken to the inlet of the 2nd impeller with the help of a connecting pipe as shown in Fig. 19.12. At the outlet of the 2nd impeller, the pressure of water will be more than the pressure of water at the outlet of the 1st impeller. Thus if more impellers are mounted on the same shaft, the pressure at the outlet will be increased further.

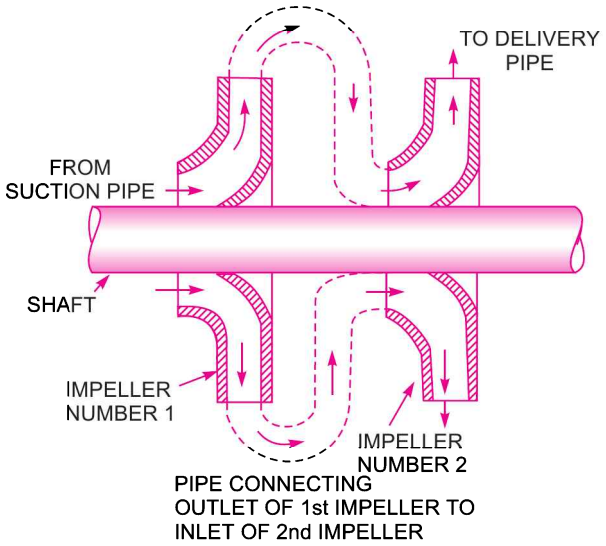

Fig. 19.12 *Two-stage pumps with impellers in series.*

Let n = Number of identical impellers mounted on the same shaft,

H_m = Head developed by each impeller.

Then total head developed

$$= n \times H_m \qquad ...(19.16)$$

The discharge passing through each impeller is same

19.6.2 Multistage Centrifugal Pumps for High Discharge. For obtaining high discharge, the pumps should be connected in parallel as shown in Fig. 19.13. Each of the pumps lifts the water from a common pump and discharges water to a common pipe to which the delivery pipes of each pump is connected. Each of the pump is working against the same head.

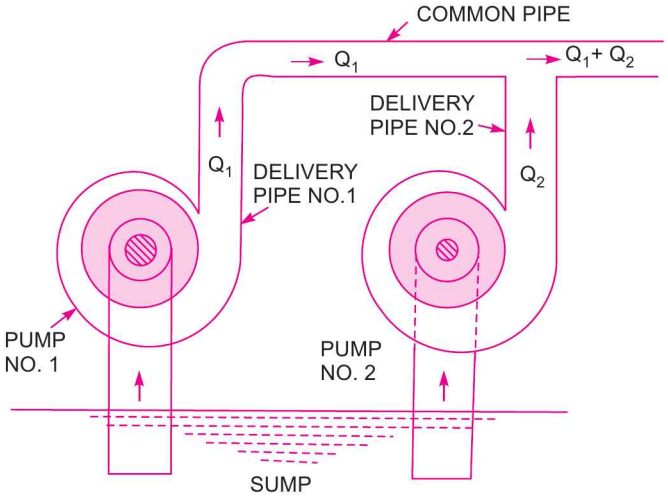

Fig. 19.13 *Pumps in parallel.*

Let n = Number of identical pumps arranged in parallel.

Q = Discharge from one pump.

$\therefore$ Total discharge $= n \times Q \qquad ...(19.17)$

Problem 19.16 *A three stage centrifugal pump has impellers 40 cm in diameter and 2 cm wide at outlet. The vanes are curved back at the outlet at 45° and reduce the circumferential area by 10%. The manometric efficiency is 90% and the overall efficiency is 80%. Determine the head generated by the pump when running at 1000 r.p.m. delivering 50 litres per second. What should be the shaft horse power ?*

Solution. Given :

Number of stages, $n = 3$

Dia. of impeller at outlet, $D_2 = 40$ cm $= 0.40$ m

Width at outlet, $B_2 = 2$ cm $= 0.02$ m

Vane angle at outlet, $\phi = 45°$

Reduction in area at outlet $= 10\% = 0.1$

$\therefore$ Area of flow at outlet $= 0.9 \times \pi D_2 \times B_2 = 0.9 \times \pi \times .4 \times .02 = 0.02262$ m^2

Manometric efficiency, $\eta_{man} = 90\% = 0.90$

Overall efficiency, $\eta_o = 80\% = 0.80$

Speed, $N = 1000$ r.p.m.

Discharge, $Q = 50$ litres/s $= 0.05$ m^3/s

Determine : (*i*) Head generated by the pump and

(*ii*) Shaft power.

Velocity of flow at outlet, $V_{f_2} = \dfrac{\text{Discharge}}{\text{Area of flow}} = \dfrac{0.05}{.02262} = 2.21$ m/s

Tangential velocity of impeller at outlet,

$$u_2 = \frac{\pi D_2 N}{60} = \frac{\pi \times 0.4 \times 1000}{60} = 20.94 \text{ m/s}$$

Refer to Fig. 19.9. From velocity triangle at outlet,

$$\tan \phi = \frac{V_{f_2}}{u_2 - V_{w_2}}$$

$$\therefore \quad u_2 - V_{w_2} = \frac{V_{f_2}}{\tan \phi} = \frac{2.21}{\tan 45^\circ} = 2.21 \text{ m/s}$$

$$\therefore \quad V_{w_2} = u_2 - 2.21 = 20.94 - 2.21 = 18.73 \text{ m/s}$$

Using equation (19.8), $\eta_{man} = \dfrac{gH_m}{V_{w_2} u_2}$, $0.90 = \dfrac{9.81 \times H_m}{18.73 \times 20.94}$

$$\therefore \quad H_m = \frac{0.90 \times 18.73 \times 20.94}{9.81} = 35.98 \text{ m.}$$

Using equation (19.16) for total head generated by pump,

$$= n \times H_m = 3 \times 35.98 = \textbf{107.94 m. Ans.}$$

$$\therefore \text{ Power output of the pump } = \frac{\text{Weight of water lifted} \times \text{Total head}}{1000}$$

$$= \frac{\rho g \times Q \times 107.94}{1000} = \frac{1000 \times 9.81 \times 0.05 \times 107.94}{1000} = 52.94 \text{ kW.}$$

Using equation (19.10), we have $\eta_o = \dfrac{\text{Power output of pump}}{\text{Power input to the pump}} = \dfrac{52.94}{\text{S.P.}}$

$$\therefore \text{ Shaft power } = \frac{52.94}{\eta_o} = \frac{52.94}{0.80} = \textbf{66.175 kW. Ans.}$$

Problem 19.17 *A four-stage centrifugal pump has four identical impellers, keyed to the same shaft. The shaft is running at 400 r.p.m. and the total manometric head developed by the multistage pump is 40 m. The discharge through the pump is 0.2 m^3/s. The vanes of each impeller are having outlet angle as 45°. If the width and diameter of each impeller at outlet is 5 cm and 60 cm respectively, find the manometric efficiency.*

Solution. Given :

Number of stage, $n = 4$

Speed, $N = 400$ r.p.m.

Total manometric head = 40 m

$\therefore$ Manometric head for each stage, $H_m = \dfrac{40}{4} = 10.0$ m

Discharge, $Q = 0.2$ m^3/s

Outlet vane angle, $\phi = 45°$

Width at outlet, $B_2 = 5$ cm $= 0.05$ m

Dia. at outlet, $D_2 = 60$ cm $= 0.6$ m

Tangential velocity of impeller at outlet, $u_2 = \dfrac{\pi D_2 N}{60} = \dfrac{\pi \times 0.6 \times 400}{60} = 12.56$ m/s

Velocity of flow at outlet, $V_{f_2} = \dfrac{\text{Discharge}}{\text{Area of flow}} = \dfrac{0.20}{\pi D_2 B_2} = \dfrac{0.20}{\pi \times 0.6 \times 0.5} = 2.122$ m/s

Refer to Fig. 19.9. From velocity triangle at outlet,

$$\tan \phi = \frac{V_{f_2}}{u_2 - V_{w_2}}$$

$$u_2 - V_{w_2} = \frac{V_{f_2}}{\tan \phi} = \frac{2.122}{\tan 45°} = 2.122 \text{ m/s}$$

$\therefore$ $V_{w_2} = u_2 - 2.122 = 12.56 - 2.122 = 10.438$

Using equation (19.8), $\eta_{man} = \dfrac{gH_m}{V_{w_2} u_2} = \dfrac{9.81 \times 10.0}{10.438 \times 12.56} =$ **0.7482** or **74.82%. Ans.**

▶ 19.7 SPECIFIC SPEED OF A CENTRIFUGAL PUMP (N_s)

The specific speed of a centrifugal pump is defined as the speed of a geometrically similar pump which would deliver *one cubic metre* of liquid per second against a head of *one metre*. It is denoted by 'N_s'.

19.7.1 Expression for Specific Speed for a Pump. The discharge, Q, for a centrifugal pump is given by the relation

$$Q = \text{Area} \times \text{Velocity of flow}$$
$$= \pi D \times B \times V_f \text{ or } Q \propto D \times B \times V_f \quad ...(i)$$

where D = Diameter of the impeller of the pump and

B = Width of the impeller.

We know that $B \propto D$

$\therefore$ From equation *(i)*, we have $Q \propto D^2 \times V_f$ ...(*ii*)

We also know that tangential velocity is given by

$$u = \frac{\pi DN}{60} \propto DN \quad ...(iii)$$

Now the tangential velocity (u) and velocity of flow (V_f) are related to the manometric head (H_m) as

$$u \propto V_f \propto \sqrt{H_m} \quad ...(iv)$$

Substituting the value of u in equation (*iii*), we get

$$\sqrt{H_m} \propto DN \text{ or } D \propto \frac{\sqrt{H_m}}{N}$$

Substituting the values of D in equation (*ii*),

$$Q \propto \frac{H_m}{N^2} \times V_f$$

$$\propto \frac{H_m}{N^2} \times \sqrt{H_m} \qquad [\because \text{ From equation } (iv),\ V_f \propto \sqrt{H_m}\ ]$$

$$\propto \frac{H_m^{3/2}}{N^2}$$

$$\therefore \qquad Q = \text{K}\ \frac{H_m^{3/2}}{N^2} \qquad \ldots(v)$$

where K is a constant of proportionality.

If $H_m = 1$ m and $Q = 1\ \text{m}^3/\text{s}$, N becomes $= N_s$.

Substituting these values in equation (*v*), we get

$$1 = K\ \frac{1^{3/2}}{N_s^2} = \frac{K}{N_s^2}$$

$$\therefore \qquad K = N_s^{\,2}$$

Substituting the value of K in equation (*v*), we get

$$Q = N_s^{\,2} \frac{H_m^{3/2}}{N^2} \quad \text{or} \quad N_s^{\,2} = \frac{N^2 Q}{H_m^{3/2}}$$

$$\therefore \qquad N_s = \frac{N\sqrt{Q}}{H_m^{3/4}} \qquad \ldots(19.18)$$

▶ 19.8 MODEL TESTING OF CENTRIFUGAL PUMPS

Before manufacturing the large sized pumps, their models which are in complete similarity with the actual pumps (also called prototypes) are made. Tests are conducted on the models and performance of the prototypes are predicted. The complete similarity between the model and actual pump (prototype) will exist if the following conditions are satisfied :

1. Specific speed of model = Specific speed of prototype

$$(N_s)_m = (N_s)_p \quad \text{or} \quad \left(\frac{N\sqrt{Q}}{H_m^{3/4}}\right)_m = \left(\frac{N\sqrt{Q}}{H_m^{3/4}}\right)_p \qquad \ldots(19.19)$$

2. Tangential velocity (u) is given by $u = \dfrac{\pi DN}{60}$ also $u \propto \sqrt{H_m}$

$$\therefore \qquad \sqrt{H_m} \propto DN$$

$$\therefore \qquad \frac{\sqrt{H_m}}{DN} = \text{Constant} \qquad \ldots(19.19\ A)$$

or $$\left(\frac{\sqrt{H_m}}{DN}\right)_m = \left(\frac{\sqrt{H_m}}{DN}\right)_p \quad ...(19.20)$$

3. From equation (*ii*) of Art. 19.7.1, we have

$$Q \propto D^2 \times V_f \qquad \text{where } V_f \propto u \propto DN$$
$$\propto D^2 \times D \times N$$
$$\propto D^3 \times N$$

$$\therefore \quad \frac{Q}{D^3N} = \text{Constant or } \left(\frac{Q}{D^3N}\right)_m = \left(\frac{Q}{D^3N}\right)_p \quad ...(19.21)$$

4. Power of the pump, $$P = \frac{\rho \times g \times Q \times H_m}{75}$$

$$\therefore \quad P \propto Q \times H_m$$
$$\propto D^3 \times N \times H_m \qquad (\because \quad Q \propto D^3N)$$
$$\propto D^3N \times D^2N^2 \qquad (\because \quad \sqrt{H_m} \propto DN)$$
$$\propto D^5N^3$$

$$\therefore \quad \frac{P}{D^5N^3} = \text{Constant} \quad \text{or} \quad \left(\frac{P}{D^5N^3}\right)_m = \left(\frac{P}{D^5N^3}\right)_p \quad ...(19.22)$$

Problem 19.18 *A single-stage centrifugal pump with impeller diameter of 30 cm rotates at 2000 r.p.m. and lifts 3 m^3 of water per second to a height of 30 m with an efficiency of 75%. Find the number of stages and diameter of each impeller of a similar multistage pump to lift 5 m^3 of water per second to a height of 200 metres when rotating at 1500 r.p.m.*

Solution. Given :

Single-stage pump :

Diameter of impeller, $D_1 = 30 \text{ cm} = 0.30 \text{ m}$

Speed, $N_1 = 2000$ r.p.m.

Discharge, $Q_1 = 3 \text{ m}^3/\text{s}$

Height, $H_{m_1} = 30$ m

Efficiency, $\eta_{man} = 75\% = 0.75$.

Multistage similar pump :

Discharge, $Q_2 = 5 \text{ m}^3/\text{s}$

Total height $= 200$ m

Let the height per stage $= H_{m_2}$

Speed, $N_2 = 1500$ r.p.m.

Diameter of each impeller $= D_2$

Specific speed should be same. Hence, applying equation (19.19) as

$$\left(\frac{N\sqrt{Q}}{H_m^{3/4}}\right)_1 = \left(\frac{N\sqrt{Q}}{H_m^{3/4}}\right)_2$$

$$\therefore \quad \frac{N_1\sqrt{Q_1}}{H_{m_1}^{3/4}} = \frac{N_2\sqrt{Q_2}}{H_{m_2}^{3/4}} \quad \text{or} \quad \frac{2000\times\sqrt{3}}{30^{3/4}} = \frac{1500\times\sqrt{5}}{H_{m_2}^{3/4}}$$

$$\therefore \quad H_{m_2}^{3/4} = \frac{1500\times\sqrt{5}\times 30^{3/4}}{2000\times\sqrt{3}} = \frac{1500}{2000}\times\sqrt{\frac{5}{3}}\times 12.818 = 12.411$$

$$\therefore \quad H_{m_2} = (12.411)^{4/3} = 28.71 \text{ m}$$

$$\therefore \quad \text{Number of stages} = \frac{\text{Total head}}{\text{Head per stage}} = \frac{200}{28.71} = 6.96 \simeq \textbf{7. Ans.}$$

Using equation (19.20), we have

$$\frac{\sqrt{H_{m_1}}}{D_1N_1} = \frac{\sqrt{H_{m_2}}}{D_2N_2} \quad \text{or} \quad \frac{\sqrt{30}}{0.30\times 2000} = \frac{\sqrt{28.71}}{D_2\times 1500}$$

$$\therefore \quad D_2 = \frac{0.30\times 2000\times\sqrt{28.71}}{1500\times\sqrt{30}} = 0.3913 \text{ m} = \textbf{391.3 mm. Ans.}$$

Problem 19.19 *Find the number of pumps required to take water from a deep well under a total head of 89 m. All the pumps are identical and are running at 800 r.p.m. The specific speed of each pump is given as 25 while the rated capacity of each pump is 0.16 m^3/s.*

Solution. Given :

Total head = 89 m
Speed, N = 800 r.p.m.
Specific speed, N_s = 25
Rate capacity, Q = 0.16 m^3/s
Let H_m = Head developed by each pump.

Using equation (19.18), $N_s = \dfrac{N\sqrt{Q}}{H_m^{3/4}}$

$$25 = \frac{800\times\sqrt{0.16}}{H_m^{3/4}}$$

$$\therefore \quad H_m^{3/4} = \frac{800\times\sqrt{0.16}}{25} = 12.8$$

$$\therefore \quad H_m = (12.8)^{4/3} = 29.94 \text{ m}$$

$$\therefore \quad \text{Number of pumps required} = \frac{\text{Total head}}{\text{Head developed by one pump}} = \frac{89}{29.94} \simeq \textbf{3. Ans.}$$

As the total head is more than the head developed by one pump, the pumps should be connected in series.

Problem 19.20 *Two geometrically similar pumps are running at the same speed of 1000 r.p.m. One pump has an impeller diameter of 0.30 metre and lifts water at the rate of 20 litres per second against a head of 15 metres. Determine the head and impeller diameter of the other pump to deliver half the discharge.*

Solution. Given :

For pump No. 1,

Speed, $N_1 = 1000$ r.p.m.

Diameter, $D_1 = 0.30$ m

Discharge, $Q_2 = 20$ litres/s $= 0.02$ m^3/s

Head, $H_{m_1} = 15$ m

For pump No. 2,

Speed, $N_2 = 1000$ r.p.m.

Discharge, $Q_2 = \frac{Q_1}{2} = \frac{20}{2} = 10$ litres/s $= 0.01$ m^3/s.

Let D_2 = Diameter of impeller

H_{m_2} = Head developed.

Using equation (19.19), $\frac{N_1\sqrt{Q_1}}{H_{m_1}^{3/4}} = \frac{N_2\sqrt{Q_2}}{H_{m_2}^{3/4}}$

$\therefore \quad \frac{1000 \times \sqrt{.02}}{15^{3/4}} = \frac{1000 \times \sqrt{.01}}{H_{m_2}^{3/4}}$

or $H_{m_2}^{3/4} = \frac{1000 \times \sqrt{.01} \times 15^{3/4}}{1000 \times \sqrt{.02}} = \sqrt{\frac{.01}{.02}} \times 7.622 = 5.389$

$\therefore \quad H_{m_2} = (5.389)^{4/3} =$ **9.44 m. Ans.**

Using equation (19.20), $\left(\frac{\sqrt{H_m}}{DN}\right)_1 = \left(\frac{\sqrt{H_m}}{DN}\right)_2$ or $\frac{\sqrt{H_{m_1}}}{D_1N_1} = \frac{\sqrt{H_{m_2}}}{D_2N_2}$

$$\frac{\sqrt{15}}{0.3 \times 1000} = \frac{\sqrt{9.44}}{D_2 \times 1000}$$

$\therefore \quad D_2 = \frac{\sqrt{9.44} \times 0.3}{\sqrt{15}} = 0.238$ m $=$ **238.0 mm. Ans.**

Problem 19.21 *The diameter of a centrifugal pump, which is discharging 0.03 m^3/s of water against a total head of 20 m is 0.40 m. The pump is running at 1500 r.p.m. Find the head, discharge and ratio of powers of a geometrically similar pump of diameter 0.25 m when it is running at 3000 r.p.m.*

Solution. Given :

Centrifugal pump,

Discharge, $Q_1 = .03$ m^3/s

Head, $H_{m_1} = 20$ m

Diameter, $D_1 = 0.40$ m

Speed, $N_1 = 1500$ r.p.m.

Geometrically similar pump,

Diameter, $D_2 = 0.25$ m

Speed, $N_2 = 3000$ r.p.m.

Let Head on similar group $= H_{m_2}$

Discharge on similar pump $= Q_2$

Using equation (19.21), $\left(\frac{Q}{D^3N}\right)_1 = \left(\frac{Q}{D^3N}\right)_2$

$$\therefore \quad \frac{Q_1}{D_1^3 N_1} = \frac{Q_2}{D_2^3 N_2}$$

$$\frac{.03}{.40^3 \times 1500} = \frac{Q_2}{0.25^3 \times 3000}$$

$$\therefore \quad Q_2 = \frac{.03 \times .25^3 \times 3000}{.40^3 \times 1500} = .03 \times \left(\frac{.25}{.40}\right)^3 \times 2.0 = \mathbf{0.01465\ m^3/s.\ Ans.}$$

Using equation (19.20), we have

$$\left(\frac{\sqrt{H_m}}{DN}\right)_1 = \left(\frac{\sqrt{H_m}}{DN}\right)_2$$

or $$\frac{\sqrt{H_{m_1}}}{D_1 N_1} = \frac{\sqrt{H_{m_2}}}{D_2 N_2} \quad \therefore \quad \frac{\sqrt{20}}{0.40 \times 1500} = \frac{\sqrt{H_{m_2}}}{0.25 \times 3000}$$

or $$\sqrt{H_{m_2}} = \frac{\sqrt{20} \times 0.25 \times 3000}{0.40 \times 1500} = 5.59$$

$$\therefore \quad H_{m_2} = (5.59)^2 = \mathbf{31.25\ m.\ Ans.}$$

Using equation (19.22), we have

$$\left(\frac{P}{D^5N^3}\right)_1 = \left(\frac{P}{D^5N^3}\right)_2$$

$$\therefore \quad \frac{P_1}{D_1^5 N_1^3} = \frac{P_2}{D_2^5 N_2^3} \quad \text{or} \quad \frac{P_1}{P_2} = \frac{D_1^5 N_1^3}{D_2^5 N_2^3} = \left(\frac{D_1}{D_2}\right)^5 \times \left(\frac{N_1}{N_2}\right)^3$$

$$= \left(\frac{0.40}{0.25}\right)^5 \times \left(\frac{1500}{3000}\right)^3 = 10.485 \times .125 = \mathbf{1.31.\ Ans.}$$

Problem 19.22 *A one-fifth scale model of a pump was tested in a laboratory at 1000 r.p.m. The head developed and the power input at the best efficiency point were found to be 8 m and 30 kW respectively. If the prototype pump has to work against a head of 25 m, determine its working speed, the power required to drive it and the ratio of the flow rates handled by the two pumps.*

Solution. Given :

One-fifth scale model means that the ratio of linear dimensions of a model and its prototype is equal to 1/5.

Speed of model, $N_m = 1000$ r.p.m.

Head of model, $H_m = 8$ m

Power of model, $P_m = 30$ kW

Head of prototype, $H_p = 25$ m

Let N_p = Speed of prototype

P_p = Power of prototype

Q_p = Flow rate of prototype

Q_m = Flow rate of model

(*i*) *Speed of prototype*

Using equation (19.20), we get

$$\left(\frac{\sqrt{H}}{DN}\right)_m = \left(\frac{\sqrt{H}}{DN}\right)_p \quad \text{or} \quad \frac{\sqrt{H_m}}{D_m N_m} = \frac{\sqrt{H_p}}{D_p N_p}$$

or
$$N_p = \frac{\sqrt{H_p}}{\sqrt{H_m}} \times \frac{D_m}{D_p} \times N_m$$

$$= \frac{\sqrt{25}}{\sqrt{8}} \times \frac{1}{5} \times 1000 \qquad \left(\because \frac{D_m}{D_p} = \frac{1}{5}\right)$$

$$= \mathbf{353.5 \text{ r.p.m. Ans.}}$$

(*ii*) *Power developed by prototype*

Using equation (19.22), we get

$$\left(\frac{P}{D^5 N^3}\right)_m = \left(\frac{P}{D^5 N^3}\right)_p \quad \text{or} \quad \frac{P_m}{D_m^5 N_m^3} = \frac{P_p}{D_p^5 N_p^3}$$

or
$$P_p = P_m \times \left(\frac{D_p}{D_m}\right)^5 \times \left(\frac{N_p}{N_m}\right)^3 = 30 \times 5^5 \times \left(\frac{353.5}{1000}\right)^3 \qquad \left(\because \frac{D_p}{D_m} = \frac{5}{1}\right)$$

$$= 30 \times 3125 \times 0.04419 = \mathbf{4143 \text{ kW. Ans.}}$$

(*iii*) *Ratio of the flow rates of two pumps (i.e., model and prototype)*

$$\left(\frac{Q}{D^3 N}\right)_m = \left(\frac{Q}{D^3 N}\right)_p \quad \text{or} \quad \frac{Q_m}{D_m^3 N_m} = \frac{Q_p}{D_p^3 N_p}$$

or
$$\frac{Q_p}{Q_m} = \frac{D_p^3 N_p}{D_m^3 N_m} = \left(\frac{D_p}{D_m}\right)^3 \times \frac{N_p}{N_m} = 5^3 \times \frac{353.5}{1000} \qquad \left(\because \frac{D_p}{D_m} = \frac{5}{1}\right)$$

$$= \mathbf{44.1875. \text{ Ans.}}$$

▶ 19.9 PRIMING OF A CENTRIFUGAL PUMP

Priming of a centrifugal pump is defined as the operation in which the suction pipe, casing of the pump and a portion of the delivery pipe upto the delivery valve is completely filled up from outside source with the liquid to be raised by the pump before starting the pump. Thus the air from these parts of the pump is removed and these parts are filled with the liquid to be pumped.

The work done by the impeller per unit weight of liquid per sec is known as the head generated by the pump. Equation (19.1) gives the head generated by the pump as = $\frac{1}{g} V_{w_2} u_2$ metre. This equation is independent of the density of the liquid. This means that when pump is running in air, the head generated is in terms of metre of air. If the pump is primed with water, the head generated is same metre of water. But as the density of air is very low, the generated head of air in terms of equivalent metre of water head is negligible and hence the water may not be sucked from the pump. To avoid this difficulty, priming is necessary.

▶ 19.10 CHARACTERISTIC CURVES OF CENTRIFUGAL PUMPS

Characteristic curves of centrifugal pumps are defined as those curves which are plotted from the results of a number of tests on the centrifugal pump. These curves are necessary to predict the behaviour and performance of the pump when the pump is working under different flow rate, head and speed. The following are the important characteristic curves for pumps :

1. Main characteristic curves,
2. Operating characteristic curves, and
3. Constant efficiency or Muschel curves.

19.10.1 Main Characteristic Curves. The main characteristic curves of a centrifugal pump consists of variation of head (manometric head, H_m), power and discharge with respect to speed. For plotting curves of manometric head *versus* speed, discharge is kept constant. For plotting curves of discharge *versus* speed, manometric head (H_m) is kept constant. And for plotting curves of power *versus* speed, the manometric head and discharge are kept constant. Fig. 19.14 shows main characteristic curves of a pump.

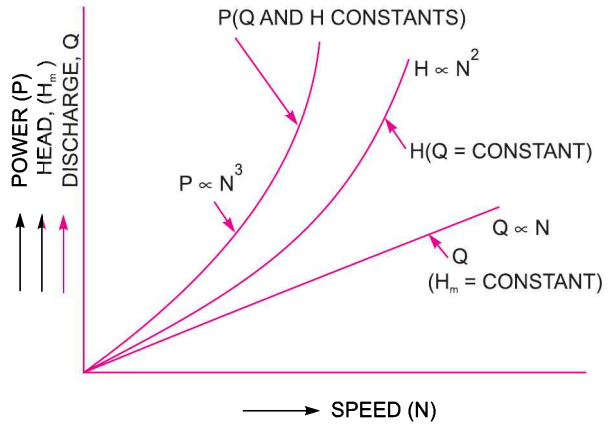

Fig. 19.14 *Main characteristic curves of a pump.*

For plotting the graph of H_m versus speed (N), the discharge is kept constant. From equation (19.19 *A*), it is clear that $\sqrt{H_m}/DN$ is a constant or $H_m \propto N^2$. This means that head developed by a pump is proportional to N^2. Hence the curve of H_m v/s N is a parabolic curves as shown in Fig. 19.14.

From equation (19.22), it is clear that P/D^5N^3 is a constant. Hence $P \propto N^3$. This means that the curve P v/s N is a cubic curve as shown in Fig. 19.14.

Equation (19.21), shows that $\frac{Q}{D^3N}$ = constant. This means $Q \propto N$ for a given pump. Hence the curve Q v/s N is a straight line as shown in Fig. 19.14.

19.10.2 Operating Characteristic Curves. If the speed is kept constant, the variation of manometric head, power and efficiency with respect to discharge gives the operating characteristics of the pump. Fig. 19.15 shows the operating characteristic curves of a pump.

The input power curve for pumps shall not pass through the origin. It will be slightly away from the origin on the y-axis, as even at zero discharge some power is needed to overcome mechanical losses.

The head curve will have maximum value of head when discharge is zero.

The output power curve will start from origin as at $Q = 0$, output power (ρQgH) will be zero.

The efficiency curve will start from origin as at $Q = 0$, $\eta = 0$ $\left(\because \quad \eta = \frac{\text{Output}}{\text{Input}}\right)$

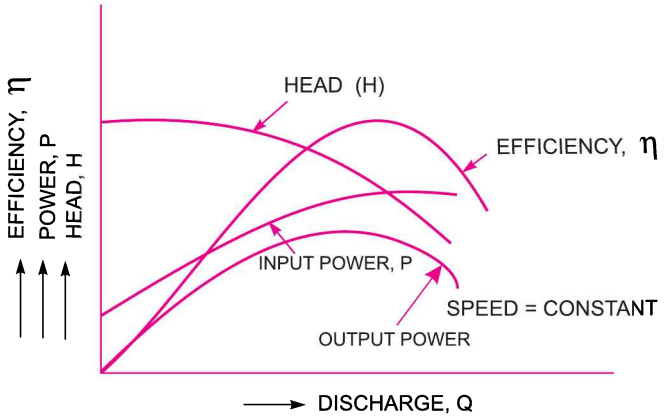

Fig. 19.15 *Operating characteristic curves of a pump.*

19.10.3 Constant Efficiency Curves. For obtaining constant efficiency curves for a pump, the head *versus* discharge curves and efficiency *versus* discharge curves for different speed are used. Fig. 19.16 (*a*) shows the head *versus* discharge curves for different speeds. The efficiency *versus* discharge curves for the different speeds are as shown in Fig. 19.16 (*b*). By combining these curves ($H \sim Q$ curves and $\eta \sim Q$ curves), constant efficiency curves are obtained as shown in Fig. 19.16 *(a)*.

For plotting the constant efficiency curves (also known as iso-efficiency curves), horizontal lines representing constant efficiencies are drawn on the $\eta \sim Q$ curves. The points, at which these lines cut the efficiency curves at various speeds, are transferred to the corresponding $H \sim Q$ curves. The points having the same efficiency are then joined by smooth curves. These smooth curves represents the iso-efficiency curves.

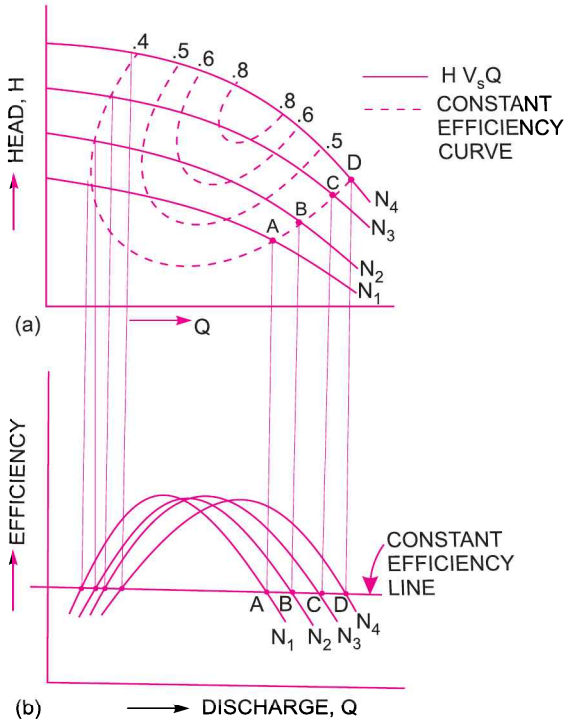

Fig. 19.16 *Constant efficiency curves of a pump.*

▶ 19.11 CAVITATION

Cavitation is defined as the phenomenon of formation of vapour bubbles of a flowing liquid in a region where the pressure of the liquid falls below its vapour pressure and the sudden collapsing of these vapour bubbles in a region of higher pressure. When the vapour bubbles collapse, a very high pressure is created. The metallic surfaces, above which these vapour bubbles collapse, is subjected to these high pressures, which cause pitting action on the surface. Thus cavities are formed on the metallic surface and also considerable noise and vibrations are produced.

Cavitation includes formation of vapour bubbles of the flowing liquid and collapsing of the vapour bubbles. Formation of vapour bubbles of the flowing liquid take place only whenever the pressure in any region falls below vapour pressure. When the pressure of the flowing liquid is less than its vapour pressure, the liquid starts boiling and vapour bubbles are formed. These vapour bubbles are carried along with the flowing liquid to higher pressure zones where these vapours condense and bubbles collapse. Due to sudden collapsing of the bubbles on the metallic surface, high pressure is produced and metallic surfaces are subjected to high local stresses. Thus the surfaces are damaged.

19.11.1 Precaution Against Cavitation. The following precautions should be taken against cavitation :

(*i*) The pressure of the flowing liquid in any part of the hydraulic system should not be allowed to fall below its vapour pressure. If the flowing liquid is water, then the absolute pressure head should not be below 2.5 m of water.

(*ii*) The special materials or coatings such as aluminium-bronze and stainless steel, which are cavitation resistant materials, should be used.

19.11.2 Effects of Cavitation. The following are the effects of cavitation :

(*i*) The metallic surfaces are damaged and cavities are formed on the surfaces.

(*ii*) Due to sudden collapse of vapour bubble, considerable noise and vibrations are produced.

(*iii*) The efficiency of a turbine decreases due to cavitation. Due to pitting action, the surface of the turbine blades becomes rough and the force exerted by water on the turbine blades decreases. Hence, the work done by water or output horse power becomes less and thus efficiency decreases.

19.11.3 Hydraulic Machines Subjected to Cavitation. The hydraulic machines subjected to cavitation are reaction turbines and centrifugal pumps.

19.11.4 Cavitation in Turbines. In turbines, only reaction turbines are subjected to cavitation. In reaction turbines the cavitation may occur at the outlet of the runner or at the inlet of the draft-tube where the pressure is considerably reduced (*i.e.*, which may be below the vapour pressure of the liquid flowing through the turbine). Due to cavitation, the metal of the runner vanes and draft-tube is gradually eaten away, which results in lowering the efficiency of the turbine. Hence, the cavitation in a reaction turbine can be noted by a sudden drop in efficiency. In order to determine whether cavitation will occur in any portion of a reaction turbine, the critical value of Thoma's cavitation factor (σ, sigma) is calculated.

Thoma's Cavitation Factor for Reaction Turbines. Prof. D. Thoma suggested a dimensionless number, called after his name Thoma's cavitation factor σ (sigma), which can be used for determining the region where cavitation takes place in reaction turbines. The mathematical expression for the Thoma's cavitation factor is given by

$$\sigma = \frac{H_b - H_s}{H} = \frac{(H_{atm} - H_v) - H_s}{H} \qquad ...(19.23)$$

where H_b = Barometric pressure head in m of water,

H_{atm} = Atmospheric pressure head in m of water,

H_v = Vapour pressure head in m of water,

H_s = Suction pressure at the outlet of reaction turbine in m of water or height of turbine runner above the tail water surface,

H = Net head on the turbine in m.

19.11.5 Cavitation in Centrifugal Pumps. In centrifugal pumps the cavitation may occur at the inlet of the impeller of the pump, or at the suction side of the pumps, where the pressure is considerably reduced. Hence if the pressure at the suction side of the pump drops below the vapour pressure of the liquid then the cavitation may occur. The cavitation in a pump can be noted by a sudden drop in efficiency and head. In order to determine whether cavitation will occur in any portion of the suction side of the pump, the critical value of Thoma's cavitation factor (σ) is calculated.

Thoma's Cavitation Factor for Centrifugal Pumps. The mathematical expression for Thoma's cavitation factor for centrifugal pump is given by

$$\sigma = \frac{(H_b) - H_S - h_{LS}}{H} = \frac{(H_{atm} - H_V) - H_S - h_{LS}}{H} \qquad ...(19.24)$$

where H_{atm} = Atmospheric pressure head in m of water or absolute pressure head at the liquid surface in pump,
H_V = Vapour pressure head in m of water,
H_S = Suction pressure head in m of water,
h_{LS} = Head lost due to friction in suction pipe, and
H = Head developed by the pump.

The value of Thoma's cavitation factor (σ) for a particular type of turbine or pump is calculated from equations (19.23) or (19.24). This value of Thoma's cavitation factor (σ) is compared with critical cavitation factor (σ_c) for that type of turbine pump. If the value of σ is greater than σ_c, the cavitation will not occur in that turbine or pump. The critical cavitation factor (σ_c) may be obtained from tables or empirical relationships.

The following empirical relationships are used for obtaining the value of σ_c for different turbines :

For Francis turbines,
$$\sigma_c = 0.625 \left(\frac{N_s}{380.78}\right)^2 \qquad ...(19.25)$$
$$\simeq 431 \times 10^{-8} \text{ Ns}^2 \qquad ...(19.26)$$

For Propeller turbines,
$$\sigma_c = 0.28 + \left[\frac{1}{7.5}\left(\frac{N_s}{380.78}\right)^3\right] \qquad ...(19.27)$$

In the above expressions N_s is in (r.p.m., kW, m) units. If N_s is in (r.p.m., h.p., m) units, the empirical relationships would be as follows :

For Francis turbines,
$$\sigma_c = 0.625 \left(\frac{N_s}{444}\right)^2 \qquad ...(19.28)$$
$$\simeq 317 \times 10^{-8} \times N_s^2 \qquad ...(19.29)$$

For Propeller turbines,
$$\sigma_c = 0.28 + \left[\frac{1}{7.5}\left(\frac{N_s}{444}\right)^3\right] \qquad ...(19.30)$$

Problem 19.23 *A Francis turbine has been manufactured to develop 15000 horse power at the head of 81 m and speed 375 r.p.m. The mean atmospheric pressure at the site is 1.03 kgf/cm^2 and vapour pressure 0.03 kgf/cm^2. Calculate the maximum permissible height of the runner above the tail water level to ensure cavitation free operation. The critical cavitation factor for Francis turbine is given by*

$$\sigma_c = 317 \times 10^{-8} \times N_s^2$$

where N_s is the specific speed of the turbine in M.K.S. units.

Solution. Given :

Horse power developed, $P = 15000$
Head, $H = 81$ m
Speed, $N = 375$ r.p.m.
Atmospheric pressure, $p_a = 1.03$ kgf/cm^2 $= 1.03 \times 9.81$ N/cm^2
$= 1.03 \times 9.81 \times 10^4$ N/m^2

$\therefore$ Atmospheric pressure head in meter of water,

$$H_{atm} = \frac{p_a}{\rho g} = \frac{1.03 \times 9.81 \times 10^4}{1000 \times 9.81} = 10.3 \text{ m}$$

Vapour pressure, $p_v = 0.03 \text{ kgf/cm}^2 = 0.03 \times 9.81 \text{ N/cm}^2 = 0.03 \times 9.81 \times 10^4 \text{ N/m}^2$

$\therefore$ Vapour pressure head in meter of water,

$$H_v = \frac{p_v}{\rho g} = \frac{0.03 \times 9.81 \times 10^4}{1000 \times 9.81} = 0.3 \text{ m}$$

Critical cavitation factor, $\sigma_c = 317 \times 10^{-8} \ N_s^2$ ...(*i*)

where N_s is the specific speed of the turbine in M.K.S. units *i.e.,* (r.p.m., h.p., m) units.

Now specific speed of turbine is given by

$$N_s = \frac{N\sqrt{P}}{H^{5/4}} = \frac{375 \times \sqrt{15000}\ *}{81^{5/4}} = 189 \text{ r.p.m.}$$

Substituting this value in equation (*i*), we get

$$\sigma_c = 317 \times 10^{-8} \times 189^2 = 0.1132$$

Now let H_s = Suction pressure head in meter of water at the outlet of Francis turbine or height of the turbine runner above the tail water surface.

Now using equation (19.23), we get

$$\sigma_c = \frac{H_{atm} - H_v - H_s}{H} \quad \text{or} \quad 0.1132 = \frac{10.3 - 0.3 - H_s}{81}$$

or $0.1132 \times 81 = 10 - H_s$ or $H_s = 10 - 0.1132 \times 81 =$ **0.8308 m. Ans.**

Hence, maximum permissible height is 0.83 m above the tail water level.

▶ 19.12 MAXIMUM SUCTION LIFT (or SUCTION HEIGHT)

Fig. 19.17 shows a centrifugal pump that lifts a liquid from a sump. The free surface of liquid is at a depth of h_s below the pump axis. The liquid is flowing with a velocity v_s in the suction pipe.

Let h_s = Suction height (or lift)

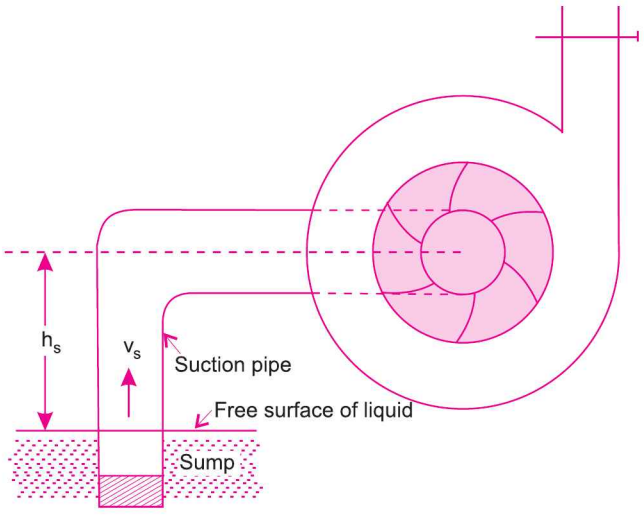

Fig. 19.17

* Here power P should be taken in horse power and not in kW.

Applying Bernoulli's equation at the free surface of liquid in the sump and section 1 in the suction pipe just at the inlet of the pump and taking the free surface of liquid as datum line, we get

$$\frac{p_a}{\rho g} + \frac{V_a^2}{2g} + Z_a = \frac{p_1}{\rho g} + \frac{V_1^2}{2g} + Z_1 + h_L \qquad ...(i)$$

where p_a = Atmospheric pressure on the free surface of liquid,
V_a = Velocity of liquid at the free surface of liquid $\simeq 0$,
Z_a = Height of free surface from datum line = 0,
p_1 = Absolute pressure at the inlet of pump,
V_1 = Velocity of liquid through suction pipe = v_s,
Z_1 = Height of inlet of pump from datum line = h_s,
h_L = Loss of head in the foot valve, strainer and suction pipe = h_{fs}.

Hence equation (*i*), after substituting the above values becomes as

$$\frac{p_a}{\rho g} + 0 + 0 = \frac{p_1}{\rho g} + \frac{v_s^2}{2g} + h_s + h_{fs}$$

or
$$\frac{p_a}{\rho g} = \frac{p_1}{\rho g} + \frac{v_s^2}{2g} + h_s + h_{fs}$$

or
$$\frac{p_1}{\rho g} = \frac{p_a}{\rho g} - \left(\frac{v_s^2}{2g} + h_s + h_{fs}\right) \qquad ...(ii)$$

For finding the maximum suction lift, the pressure at the inlet of the pump should not be less than the vapour pressure of the liquid. Hence for the limiting case, taking the pressure at the inlet of pump equal to vapour pressure of the liquid, we get

$p_1 = p_v$, where p_v = vapour pressure of the liquid in absolute units.

Now the equation (*ii*) becomes as

$$\frac{p_v}{\rho g} = \frac{p_a}{\rho g} - \left(\frac{v_s^2}{2g} + h_s + h_{fs}\right)$$

or
$$\frac{p_a}{\rho g} = \frac{p_v}{\rho g} + \frac{v_s^2}{2g} + h_s + h_{fs} \qquad (\because \quad p_1 = p_v) \ ...(iii)$$

Now
$$\frac{p_a}{\rho g} = \text{Atmospheric pressure head} = H_a \text{ (meter of liquid)}$$

$$\frac{p_v}{\rho g} = \text{Vapour pressure head} = H_v \text{ (meter of liquid)}$$

Now, equation (*iii*) becomes as

$$H_a = H_v + \frac{v_s^2}{2g} + h_s + h_{fs}$$

or
$$h_s = H_a - H_v - \frac{v_s^2}{2g} - h_{fs} \qquad ...(19.31)$$

Equation (19.31) gives the value of maximum suction lift (or maximum suction height) for a centrifugal pump. Hence, the suction height of any pump should not be more than that given by equation (19.31). If the suction height of the pump is more, then vaporization of liquid at inlet of pump will take place and there will be a possibility of cavitation.

▶ 19.13 NET POSITIVE SUCTION HEAD (NPSH)

The term NPSH (Net Positive Suction Head) is very commonly used in the pump industry. Actually the minimum suction conditions are more frequently specified in terms of NPSH.

The net positive suction head (NPSH) is defined as the *absolute* pressure head at the inlet to the pump, minus the vapour pressure head (in absolute units) plus the velocity head.

$\therefore$ NPSH = Absolute pressure head at inlet of the pump – vapour pressure head (absolute units) + velocity head

$$= \frac{p_1}{\rho g} - \frac{p_v}{\rho g} + \frac{v_s^2}{2g} \quad (\because \text{ Absolute pressure at inlet of pump} = p_1) \quad \ldots (19.32)$$

But from equation (*ii*) of Art. 19.12, the absolute pressure head at inlet of the pump is given by as

$$\frac{p_1}{\rho g} = \frac{p_a}{\rho g} - \left(\frac{v_s^2}{2g} + h_s + h_{f_s} \right)$$

Substituting this value in equation (19.32) , we get

$$\text{NPSH} = \left[\frac{p_a}{\rho g} - \left(\frac{v_s^2}{2g} + h_s + h_{f_s} \right) \right] - \frac{p_v}{\rho g} + \frac{v_s^2}{2g}$$

$$= \frac{p_a}{\rho g} - \frac{p_v}{\rho g} - h_s - h_{f_s}$$

$$= H_a - H_v - h_s - h_{f_s}$$

$$\left(\because \frac{p_a}{\rho g} = H_a = \text{Atmospheric pressure head}, \frac{p_v}{\rho g} = H_v = \text{Vapour pressure head} \right)$$

$$= \left[\left(H_a - h_s - h_{f_s} \right) - H_v \right] \quad \ldots (19.33)$$

The right hand side of equation (19.33) is the total suction head. Hence NPSH is equal to total suction head. Thus NPSH may also be defined as the total head required to make the liquid flow through the suction pipe to the pump impeller.

For any pump installation, a distinction is made between the required NPSH and the available NPSH. The value of required NPSH is given by the pump manufacturer. This value can also be determined experimentally. For determining its value, the pump is tested and minimum value of h_s is obtained at which the pump gives maximum efficiency without any objectional noise (*i.e.,* cavitation free). The required NPSH varies with the pump design, speed of the pump and capacity of the pump.

When the pump is installed, the available NPSH is calculated from equation (19.33). In order to have cavitation free operation of centrifugal pump, the available NPSH should be greater than the required NPSH.

▶ 19.14 CAVITATION IN CENTRIFUGAL PUMP

Thoma's cavitation factor is used to indicate whether cavitation will occur in pumps. Equation (19.24) gives the value of Thoma's cavitation factor for pumps as

$$\sigma = \frac{\left(H_{atm} - H_v \right) - H_s - h_{f_s}}{H}$$

$$= \frac{H_a - H_v - h_s - h_{f_s}}{H_m} \quad (\because H_s = h_s \text{ and } h_{L_s} = h_{f_s}) \ (H = H_m \text{ for pumps})$$

But from equation (19.33), we have

$$H_a - H_v - h_s - h_{f_s} = \text{NPSH} \qquad \text{(Net position suction head)}$$

$$\therefore \qquad \sigma = \frac{\text{NPSH}}{H_m} \qquad ...(19.34)$$

If the value of σ (calculated from equation 19.34) is less than the critical value, σ_c then cavitation will occur in the pumps. The value of σ_c depends upon the specific speed of the pump $\left(N_s = \frac{N\sqrt{Q}}{H_m^{3/4}}\right)$. The following empirical relation is used to determine the value of σ_c.

$$\sigma_c = 0.103 \left(\frac{N_s}{1000}\right)^{4/3}$$

$$= 0.103 \frac{N_s^{4/3}}{\left(10^3\right)^{4/3}} = \frac{0.103\, N_s^{4/3}}{10^4}$$

$$= 1.03 \times 10^{-3}\, N_s^{4/3} \qquad ...(19.35)$$

Problem 19.24 *A centrifugal pump rotating at 1000 r.p.m. delivers 160 litres/s of water against a head of 30 m. The pump is installed at a place where atmospheric pressure is 1 $\times 10^5$ P_a (abs.) and vapour pressure of water is 3 kPa (abs.). The head loss in suction pipe is equivalent to 0.2 m of water. Calculate :*

(i) Minimum NPSH, and

(ii) Maximum allowable height of the pump from free surface of water in the sump.

Solution. Given :

N = 1000 r.p.m.; Q = 160 litres/s = 0.16 m^3/s.; H_m = 30 m

$p_a = 1 \times 10^5$ Pa (abs.) = 1×10^5 N/m^2 (abs.) ; $p_v = 3$ kPa (abs.) = 3×10^3 N/m^2 (abs.)

$h_{f_s} = 0.2$ m.

(*i*) *Minimum NPSH*

Using equation (19.34), we get

$$\sigma = \frac{\text{NPSH}}{H_m}$$

From the above equation, it is clear that NPSH is directly proportional to Thoma's cavitation factor (σ). NPSH will be minimum when σ is minimum. But the minimum value of σ for no cavitation is σ_c. Hence when $\sigma = \sigma_c$ then NPSH will be minimum.

$$\therefore \qquad \sigma_c = \frac{(\text{NPSH})_{\min}}{H_m}$$

or $$(\text{NPSH})_{\min} = H_m \times \sigma_c \qquad ...(i)$$

Now the critical value of σ *i.e.*, σ_c is given by equation (19.35) as

$$\sigma_c = 1.03 \times 10^{-3} \times N_s^{4/3} \qquad ...(ii)$$

where N_s = Specific speed of pump = $\frac{N\sqrt{Q}}{H_m^{3/4}}$

$$= 1000 \times \frac{\sqrt{0.16}}{30^{3/4}} \quad (\because N = 1000 \text{ r.p.m.}, Q = 0.16 \text{ m}^3/\text{s and } H_m = 30 \text{ m})$$

Substituting the value of N_s in equation (*ii*), we get

$$\sigma_c = 1.03 \times 10^{-3} \times \left[\frac{1000 \times \sqrt{0.16}}{30^{3/4}}\right]^{4/3}$$

$$= 1.03 \times 10^{-3} \times \frac{1000^{4/3} \times 0.16^{2/3}}{30} = \frac{1.03 \times 10^{-3} \times 10^4 \times 0.2947}{30}$$

$$= 0.1012$$

Substituting the value of σ_c in equation (*i*), we get

$$(\text{NPSH})_{\text{min.}} = H_m \times 0.1012$$

$$= 30 \times 0.1012 = \textbf{3.036 m. Ans.} \qquad (\because \quad H_m = 30 \text{ m})$$

(*ii*) *Maximum allowable height of the pump from free surface of water in the sump* (*i.e.*, h_s)

Let $(h_s)_{\max}$ = Max. allowable height of pump from free surface of water.

Using equation (19.33)

$$\text{NPSH} = H_a - H_v - h_s - h_{f_s} \qquad ...(i)$$

From the above equation, it is clear that for a given value of atmospheric pressure head $\left(H_a = \frac{p_a}{\rho g}\right)$, given vapour pressure head $\left(H_v = \frac{p_v}{\rho g}\right)$ and given loss of head due to friction (h_{f_s}), the value of suction head (h_s) will be maximum if NPSH is minimum.

$$\therefore \qquad (\text{NPSH})_{\min} = H_a - H_v - (h_s)_{\max} - h_{f_s} \qquad ...(ii)$$

$$\therefore \qquad (h_s)_{\max} = H_a - H_v - h_{f_s} - (\text{NPSH})_{\min} \qquad ...(iii)$$

Now $$H_a = \frac{p_a}{\rho g} = \frac{1 \times 10^5}{1000 \times 9.81} = 10.193 \text{ m of water}$$

$$H_v = \frac{p_v}{\rho g} = \frac{3 \times 10^3}{1000 \times 9.81} = 0.305 \text{ m of water}$$

$$h_{f_s} = 0.2 \text{ m and } (\text{NPSH})_{\min} = 3.036 \text{ m}$$

Substituting the values of H_a, H_v, h_{f_s} and $(\text{NPSH})_{\text{min.}}$ in equation (*iii*), we get

$$(h_s)_{\max} = 10.193 - 0.305 - 0.2 - 3.036$$

$$= \textbf{6.652 m. Ans.}$$

HIGHLIGHTS

1. The hydraulic machine which converts the mechanical energy into pressure energy by means of centrifugal force is called centrifugal pump.
2. The centrifugal pump acts as a reverse of an inward radial flow reaction turbine. The work done by the impeller (rotating part of the pump) on the water per second per unit weight of water per second flowing through the pump is given as

$$= \frac{1}{g} V_{w_2} \times u_2$$

where V_{w_2} = Velocity of whirl at outlet, and

u_2 = Tangential velocity of wheel at outlet.

3. The vertical height of the centre-line of the centrifugal pump from the water surface in the pump is called the suction head (h_s).

4. Delivery head (h_d) is the vertical distance between the centre-line of the pump and the water surface in the tank to which water is lifted.

5. Manometric head (H_m) is the head against which a centrifugal pump has to work. It is given as

(*a*) $$H_m = \frac{V_{w_2} \times u_2}{g} - \text{Loss of head in impeller and casing}$$

$$= \frac{V_{w_2} \times u_2}{g} \text{ ...if losses in pump is zero}$$

(*b*) H_m = Total head at outlet – Total head at inlet of pump

$$= \left(\frac{p_o}{\rho g} + \frac{V_o^2}{2g} + Z_o\right) - \left(\frac{p_i}{\rho g} + \frac{V_i^2}{2g} + Z_i\right)$$

(*c*) $$H_m = h_s + h_d + h_{f_s} + h_{f_d} + \frac{V_d^2}{2g}.$$

6. The efficiencies of a pump are : (*i*) Manometric efficiency (h_{man}), (*ii*) Mechanical efficiency (η_m), and (*iii*) Overall efficiency (η_o). Mathematically they are given as

$$\eta_{man} = \frac{gH_m}{V_{w_2} \times u_2}$$

$$\eta_m = \frac{\frac{W}{g}\left(\frac{V_{w_2} \times u}{75}\right)}{\text{S.P.}}, \text{ where } W = w \times Q$$

$$\eta_o = \frac{W \times H_m}{1000 \times \text{S.P.}}$$

7. The minimum speed for starting a centrifugal pump is given by $N = \dfrac{120 \times \eta_{man} \times V_{w_2} \times D_2}{\pi\left[D_2^2 - D_1^2\right]}$.

8. If a centrifugal pump consists of two or more impellers, the pump is called a multistage pump. To produce a high head, the impellers are connected in series while to discharge a large quantity of liquid, the impellers are connected in parallel.

9. The specific speed of a centrifugal pump is defined as the speed at which a pump runs when the head developed is one metre and discharge is one cubic metre. Mathematically, it is given as

$$N_s = \frac{N\sqrt{Q}}{H_m^{3/4}}, \text{ where } H_m = \text{Manometric hand.}$$

10. For complete similarity between the model and actual centrifugal pump (prototype) the following conditions should be satisfied :

(*a*) $\left(\frac{N\sqrt{Q}}{H_m^{3/4}}\right)_{\text{model}} = \left(\frac{N\sqrt{Q}}{H_m^{3/4}}\right)_{\text{prototype}}$ (*b*) $\left(\frac{\sqrt{H_m}}{DN}\right)_{\text{model}} = \left(\frac{\sqrt{H_m}}{DN}\right)_{\text{prototype}}$

(*c*) $\left(\frac{Q}{D^3N}\right)_{\text{model}} = \left(\frac{Q}{D^3N}\right)_{\text{prototype}}$ (*d*) $\left(\frac{P}{D^5N^3}\right)_{\text{model}} = \left(\frac{P}{D^5N^3}\right)_{\text{prototype}}$

11. Characteristic curves are used for predicting the behaviour and performance of a pump when it is working under different flow rate, head and speed.

12. Cavitation is defined as the phenomenon of formation of vapour bubbles and sudden collapsing of the vapour bubbles.

EXERCISE

(A) THEORETICAL PROBLEMS

1. Define a centrifugal pump. Explain the working of a single-stage centrifugal pump with sketches.

2. Differentiate between the volute casing and vortex casing for the centrifugal pump.

3. Obtain an expression for the work done by impeller of a centrifugal pump on water per second per unit weight of water.

4. Define the terms : suction head, delivery head, static head and manometric head.

5. What do you mean by manometric efficiency, mechanical efficiency and overall efficiency of a centrifugal pump?

6. How will you obtain an expression for the minimum speed for starting a centrifugal pump?

7. What is the difference between single-stage and multistage pumps? Describe multistage pump with (*a*) impellers in parallel, and (*b*) impellers in series.

8. Define specific speed of a centrifugal pump. Derive an expression for the same.

9. How does the specific speed of a centrifugal pump differ from that of a turbine ?

10. What is priming ? Why is it necessary ?

11. How the model testing of the centrifugal pumps are made?

12. What do you understand by characteristic curves of a pump? What is the significance of the characteristic curves?

13. Define cavitation. What are the effects of cavitation ? Give the necessary precautions against cavitation.

14. How will you determine the possibility of the cavitation to occur in the installation of a turbine or a pump?

15. Why are centrifugal pumps used sometimes in series and sometimes in parallel ? Draw the following characteristic curves for a centrifugal pump :

Head, power and efficiency *versus* discharge with constant speed.

16. Draw and discuss the operating characteristics of a centrifugal pump.

17. (*a*) What is cavitation and what are its causes ? How will you prevent the cavitation in hydraulic machines ?

(*b*) What is cavitation? State its effects on the performance of water turbines and also state how to prevent cavitation in water turbines.

18. Briefly state the significance of similarity parameters in hydraulic pumps.

19. The frictional torque T of a disc of diameter D rotating at a speed of N in a fluid of viscosity μ and density ρ in a turbulent flow is given by :

$$T = D^5 N^2 \rho \phi \left[\frac{\mu}{D^2 N \rho} \right]$$

Prove this by method of dimensions.

20. With a neat sketch, explain the principle and working of a centrifugal pump.

21. Explain the following terms as they are applied to a centrifugal pump :
(*i*) Static suction lift ; (*ii*) static suction head ; (*iii*) static discharge head ; and (*iv*) total static head.

22. (*a*) How does a volute casing differ from a vortex casing for the centrifugal pump ?
(*b*) What is priming ? Why is it necessary ?
(*c*) What do you mean by pump characteristics ? Briefly explain the uses of such characteristics.
(*Jawaharlal Nehru Technical University, S 2002*)

(B) NUMERICAL PROBLEMS

1. The internal and external diameters of the impeller of a centrifugal pump are 300 mm and 600 mm respectively. The pump is running at 1000 r.p.m. The vane angles at inlet and outlet are 20° and 30° respectively. The water enters the impeller radially and velocity of flow is constant. Determine the work done by the impeller per unit weight of water. [**Ans.** 68.89 Nm/N]

2. A centrifugal pump having outer diameter equal to two times the inner diameter and running at 1200 r.p.m. works against a total head of 75 m. The velocity of flow through the impeller is constant and equal to 3 m/s. The vanes are set back at an angle of 30° at outlet. If the outer diameter of the impeller is 600 mm and width at outlet is 50 mm, determine : (*a*) vane angle at inlet, (*b*) work done per second by impeller, (*c*) manometric efficiency. [**Ans.** (*a*) 9° 2′, (*b*) 346.37 kW, (*c*) 60%]

3. A centrifugal pump is running at 1000 r.p.m. The outlet vane angle of the impeller is 30° and velocity of flow at outlet is 3 m/s. The pump is working against a total head of 30 m and the discharge through the pump is 0.3 m^3/s. If the manometric efficiency of the pump is 75%, determine: (*i*) the diameter of the impeller, and (*ii*) the width of the impeller at outlet. [**Ans.** (*i*) 43.1 cm, (*ii*) 7.4 cm]

4. Find the power required to drive a centrifugal pump which delivers 0.02 m^3/s of water to a height of 30 m through a 10 cm diameter pipe and 90 m long. The overall efficiency of the pump is 70% and $f = .009$ in the formula

$$h_f = \frac{4 f l V^2}{d \times 2g}.$$

[**Ans.** 11.5 kW]

5. Find the rise in pressure in the impeller of a centrifugal pump through which water is flowing at the rate of 15 litre/s. The internal and external diameters of the impeller are 20 cm and 40 cm respectively. The widths of impeller at inlet and outlet are 1.6 cm and 0.8 cm. The pump is running at 1200 r.p.m. The water enters the impeller radially at inlet and impeller vane angle at outlet is 30°. Neglect losses through the impeller. [**Ans.** 31.85 m]

6. The diameters of an impeller of a centrifugal pump at inlet and outlet are 20 cm and 40 cm respectively. Determine the minimum speed for starting the pump if it works against a head of 25 m.
[**Ans.** 1221.2 r.p.m.]

7. The diameter of an impeller of a centrifugal pump at inlet and outlet are 300 mm and 600 mm respectively. The velocity of flow at outlet is 2.5 m/s and vanes are set back at an angle of 45° at outlet. Determine the minimum starting speed of the pump if the manometric efficiency is 75%. [**Ans.** 159.31 r.p.m.]

8. A three-stage centrifugal pump has impeller 40 cm in diameter and 2.5 cm wide at outlet. The vanes are curved back at the outlet at 30° and reduce the circumferential area by 15%. The manometric efficiency is 85% and overall efficiency is 75%. Determine the head generated by the pump when running at 12000 r.p.m. and discharge is 0.06 m^3/s. Find the shaft power also. [**Ans.** 138.75 m, 108.89 kW]

9. Find the number of pumps required to take water from a deep well under a total head of 156 m. Also the pumps are identical and are running at 1000 r.p.m. The specific speed of each pump is given as 20 while the rated capacity of each pump is 150 litre/s. [**Ans.** 3]

10. The diameter of a centrifugal pump, which is discharging 0.035 m^3/s of water against a total head of 25 m is 0.05 m. The pump is running at 1200 r.p.m. Find the head, discharge and ratio of powers of a geometrically similar pump of diameter 0.3 m when it is running at 2000 r.p.m. [**Ans.** 25 m, .0126 m^3/s, 2.777]

11. A centrifugal pump is to discharge 0.12 m^3 at a speed of 1400 r.p.m. against a head of 30 m. The diameter and width of the impeller at outlet are 25 cm and 5 cm respectively. If the manometric efficiency is 75%, determine the vane angle at outlet.

20 CHAPTER

RECIPROCATING PUMPS

▶ 20.1 INTRODUCTION

In the last chapter, we have defined the pumps as the hydraulic machines which convert the mechanical energy into hydraulic energy which is mainly in the form of pressure energy. If the mechanical energy is converted into hydraulic energy, by means of centrifugal force acting on the liquid, the pump is known as centrifugal pump. But if the mechanical energy is converted into hydraulic energy (or pressure energy) by sucking the liquid into a cylinder in which a piston is reciprocating (moving backwards and forwards), which exerts the thrust on the liquid and increases its hydraulic energy (pressure energy), the pump is known as reciprocating pump.

▶ 20.2 MAIN PARTS OF A RECIPROCATING PUMP

The following are the main parts of a reciprocating pump as shown in Fig. 20.1 :

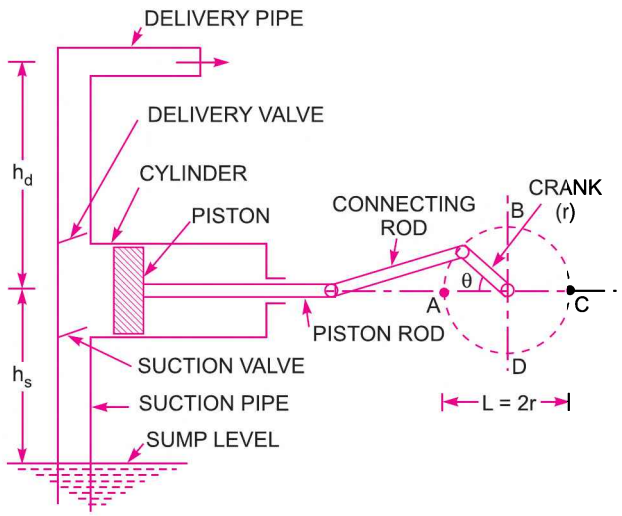

Fig. 20.1 *Main parts of a reciprocating pump.*

1. A cylinder with a piston, piston rod, connecting rod and a crank,
2. Suction pipe, 3. Delivery pipe,
4. Suction valve, and 5. Delivery valve.

▶ 20.3 WORKING OF A RECIPROCATING PUMP

Fig. 20.1 shows a single acting reciprocating pump, which consists of a piston which moves forwards and backwards in a close fitting cylinder. The movement of the piston is obtained by connecting the piston rod to crank by means of a connecting rod. The crank is rotated by means of an electric motor. Suction and delivery pipes with suction valve and delivery valve are connected to the cylinder. The suction and delivery valves are one way valves or non-return valves, which allow the water to flow in one direction only. Suction valve allows water from suction pipe to the cylinder which delivery valve allows water from cylinder to delivery pipe only.

When crank starts rotating, the piston moves to and fro in the cylinder. When crank is at A., the piston is at the extreme left position in the cylinder. As the crank is rotating from A to C, (*i.e.*, from $\theta = 0^o$ to $\theta = 180°$), the piston is moving towards right in the cylinder. The movement of the piston towards right creates a partial vacuum in the cylinder. But on the surface of the liquid in the sump atmospheric pressure is acting, which is more than the pressure inside the cylinder. Thus, the liquid is forced in the suction pipe from the sump. This liquid opens the suction valve and enters the cylinder.

When crank is rotating from C to A (*i.e.*, from $\theta = 180°$ to $\theta = 360°$), the piston from its extreme right position starts moving towards left in the cylinder. The movement of the piston towards left increases the pressure of the liquid inside the cylinder more than atmospheric pressure. Hence suction valve closes and delivery valve opens. The liquid is forced into the delivery pipe and is raised to a required height.

20.3.1 Discharge Through a Reciprocating Pump. Consider a single* acting reciprocating pump as shown in Fig. 20.1.

Let D = Diameter of the cylinder

A = Cross-sectional area of the piston or cylinder

$$= \frac{\pi}{4} D^2$$

r = Radius of crank

N = r.p.m. of the crank

L = Length of the stroke = $2 \times r$

h_s = Height of the axis of the cylinder from water surface in sump.

h_d = Height of delivery outlet above the cylinder axis (also called delivery head)

Volume of water delivered in one revolution or discharge of water in one revolution

$$= \text{Area} \times \text{Length of stroke} = A \times L$$

Number of revolution per second, $= \frac{N}{60}$

$\therefore$ Discharge of the pump per second,

Q = Discharge in one revolution × No. of revolution per second

$$= A \times L \times \frac{N}{60} = \frac{ALN}{60} \qquad ...(20.1)$$

* Single acting means the water is acting on one side of the piston only.

Weight of water delivered per second,

$$W = \rho \times g \times Q = \frac{\rho g A L N}{60}. \qquad ...(20.2)$$

20.3.2 Work done by Reciprocating Pump. Work done by the reciprocating pump per second is given by the reaction as

Work done per second = Weight of water lifted per second × Total height through which water is lifted

$$= W \times (h_s + h_d) \qquad ...(i)$$

where $(h_s + h_d)$ = Total height through which water is lifted.

From equation (20.2), Weight, W, is given by

$$W = \frac{\rho g \times A L N}{60}.$$

Substituting the value of W in equation (i), we get

$$\text{Work done per second} = \frac{\rho g \times A L N}{60} \times (h_s + h_d) \qquad ...(20.3)$$

$\therefore$ Power required to drive the pump, in kW

$$P = \frac{\text{Work done per second}}{1000} = \frac{\rho g \times A L N \times (h_s + h_d)}{60 \times 1000}$$

$$= \frac{\rho g \times A L N \times (h_s + h_d)}{60{,}000} \text{ kW} \qquad ...(20.4)$$

20.3.3 Discharge, Work done and Power Required to Drive a Double-acting Pump. In case of double-acting pump, the water is acting on both sides of the piston as shown in Fig. 20.2. Thus, we require two suction pipes and two delivery pipes for double-acting pump. When there is a suction stroke on one side of the piston, there is at the same time a delivery stroke on the other side of the piston. Thus for one complete revolution of the crank there are two delivery strokes and water is delivered to the pipes by the pump during these two delivery strokes.

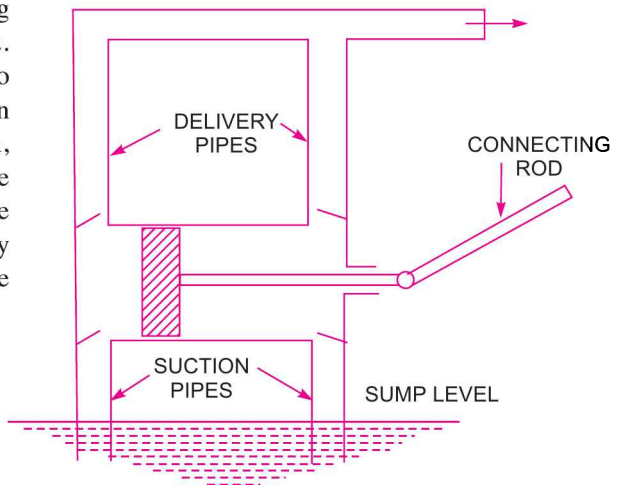

Fig. 20.2

Let D = Diameter of the piston,

d = Diameter of the piston rod

$\therefore$ Area on one side of the piston,

$$A = \frac{\pi}{4} D^2$$

Area on the other side of the piston, where piston rod is connected to the piston,

$$A_1 = \frac{\pi}{4} D^2 - \frac{\pi}{4} d^2 = \frac{\pi}{4} (D^2 - d^2).$$

∴ Volume of water delivered in one revolution of crank

$$= A \times \text{Length of stroke} + A_1 \times \text{Length of stroke}$$

$$= AL + A_1L = (A + A_1)L = \left[\frac{\pi}{4}D^2 + \frac{\pi}{4}\left(D^2 - d^2\right)\right] \times L$$

∴ Discharge of pump per second

= Volume of water delivered in one revolution × No. of revolution per second

$$= \left[\frac{\pi}{4}D^2 + \frac{\pi}{4}\left(D^2 - d^2\right)\right] \times L \times \frac{N}{60}$$

If 'd' the diameter of the piston rod is very small as compared to the diameter of the piston, then it can be neglected and discharge of pump per second,

$$Q = \left(\frac{\pi}{4}D^2 + \frac{\pi}{4}D^2\right) \times \frac{L \times N}{60} = 2 \times \frac{\pi}{4}D^2 \times \frac{L \times N}{60} = \frac{2ALN}{60} \quad ...(20.5)$$

Equation (20.5) gives the discharge of a double-acting reciprocating pump. This discharge is two times the discharge of a single-acting pump.

Work done by double-acting reciprocating pump

Work done per second = Weight of water delivered × Total height

$$= \rho g \times \text{Discharge per second} \times \text{Total height}$$

$$= \rho g \times \frac{2ALN}{60} \times (h_s + h_d) = 2\rho g \times \frac{ALN}{60} \times (h_s + h_d) \quad ...(20.6)$$

∴ Power required to drive the double-acting pump in kW,

$$P = \frac{\text{Work done per second}}{1000} = 2\rho g \times \frac{ALN}{60} \times \frac{(h_s + h_d)}{1000}$$

$$= \frac{2\rho g \times ALN \times (h_s + h_d)}{60{,}000} \quad ...(20.7)$$

▶ 20.4 SLIP OF RECIPROCATING PUMP

Slip of a pump is defined as the difference between the theoretical discharge and actual discharge of the pump. The discharge of a single-acting pump given by equation (20.1) and of a double-acting pump given by equation (20.5) are theoretical discharge. The actual discharge of a pump is less than the theoretical discharge due to leakage. The difference of the theoretical discharge and actual discharge is known as slip of the pump. Hence, mathematically.

$$\text{Slip} = Q_{th} - Q_{act} \quad ...(20.8)$$

But slip is mostly expressed as percentage slip which is given by,

$$\text{Percentage slip} = \frac{Q_{th} - Q_{act}}{Q_{th}} \times 100 = \left(1 - \frac{Q_{act}}{Q_{th}}\right) \times 100$$

$$= (1 - C_d) \times 100 \qquad \left(\because \frac{Q_{act}}{Q_{th}} = C_d\right) \quad ...(20.9)$$

where C_d = Co-efficient of discharge.

20.4.1 Negative Slip of the Reciprocating Pump. Slip is equal to the difference of theoretical discharge and actual discharge. If actual discharge is more than the theoretical discharge, the slip of the pump will become –ve. In that case, the slip of the pump is known as negative slip.

Negative slip occurs when delivery pipe is short, suction pipe is long and pump is running at high speed.

▶ 20.5 CLASSIFICATION OF RECIPROCATING PUMPS

The reciprocating pumps may be classified as :

1. According to the water being in contact with one side or both sides of the piston, and
2. According to the number of cylinders provided.

If the water is in contact with one side of the piston, the pump is known as single-acting. On the other hand, if the water is in contact with both sides of the piston, the pump is called double-acting. Hence, classification according to the contact of water is :

(*i*) Single-acting pump, and (*ii*) Double-acting pump.

According to the number of cylinder provided, the pumps are classified as :

(*i*) Single cylinder pump, (*ii*) Double cylinder pump, and

(*iii*) Triple cylinder pump.

Problem 20.1 *A single-acting reciprocating pump, running at 50 r.p.m., delivers 0.01 m^3/s of water. The diameter of the piston is 200 mm and stroke length 400 mm. Determine :*

(i) The theoretical discharge of the pump, (ii) Co-efficient of discharge, and (iii) Slip and the percentage slip of the pump.

Solution. Given :

Speed of the pump, $N = 50$ r.p.m.

Actual discharge, $Q_{act} = .01\ m^3/s$

Dia. of piston, $D = 200\ mm = .20\ m$

$\therefore$ Area, $A = \frac{\pi}{4}(.2)^2 = .031416\ m^2$

Stroke, $L = 400\ mm = 0.40\ m.$

(*i*) Theoretical discharge for single-acting reciprocating pump is given by equation (20.1) as

$$Q_{th} = \frac{A \times L \times N}{60} = \frac{.031416 \times .40 \times 50}{60} = \mathbf{0.01047\ m^3/s.\ Ans.}$$

(*ii*) Co-efficient of discharge is given by

$$C_d = \frac{Q_{act}}{Q_{th}} = \frac{0.01}{.01047} = \mathbf{0.955.\ Ans.}$$

(*iii*) Using equation (20.8), we get

$$\text{Slip} = Q_{th} - Q_{act} = .01047 - .01 = \mathbf{0.00047\ m^3/s.\ Ans.}$$

And percentage slip $= \frac{(Q_{th} - Q_{act})}{Q_{th}} \times 100 = \frac{(.01047 - .01)}{.01047} \times 100$

$$= \frac{.00047}{.01047} \times 100 = \mathbf{4.489\%.\ Ans.}$$

Problem 20.2 *A double-acting reciprocating pump, running at 40 r.p.m., is discharging 1.0 m^3 of water per minute. The pump has a stroke of 400 mm. The diameter of the piston is 200 mm. The delivery and suction head are 20 m and 5 m respectively. Find the slip of the pump and power required to drive the pump.*

Solution. Given:

Speed of pump, $N = 40$ r.p.m.

Actual discharge, $Q_{act} = 1.0 \text{ m}^3/\text{min} = \frac{1.0}{60} \text{ m}^3/\text{s} = 0.01666 \text{ m}^3/\text{s}$

Stroke, $L = 400 \text{ mm} = 0.40 \text{ m}$

Diameter of piston, $D = 200 \text{ mm} = 0.20 \text{ m}$

$\therefore$ Area, $A = \frac{\pi}{4} D^2 = \frac{\pi}{4} (.2)^2 = 0.031416 \text{ m}^2$

Suction head, $h_s = 5$ m

Delivery head, $h_d = 20$ m.

Theoretical discharge for double-acting pump is given by equation (20.5) as,

$$Q_{th} = \frac{2ALN}{60} = \frac{2 \times .031416 \times 0.4 \times 40}{60} = .01675 \text{ m}^3/\text{s}.$$

Using equation (20.8), Slip $= Q_{th} - Q_{act} = .01675 - .01666 =$ **.00009 m^3/s. Ans.**

Power required to drive the double-acting pump is given by equation (20.7) as,

$$P = \frac{2 \times \rho g \times ALN \times (h_s + h_d)}{60{,}000} = \frac{2 \times 1000 \times 9.81 \times .031416 \times .4 \times 40 \times (5 + 20)}{60{,}000}$$

= 4.109 kW. Ans.

▶ 20.6 VARIATION OF VELOCITY AND ACCELERATION IN THE SUCTION AND DELIVERY PIPES DUE TO ACCELERATION OF THE PISTON

It is mentioned in Art. 20.3 that when crank starts rotating, the piston moves forwards and backwards in the cylinder. At the extreme left position and right position of the piston in the cylinder, the velocity of the piston is zero. The velocity of the piston is maximum at the centre of the cylinder. This means that at the start of a stroke (may be suction or delivery stroke), the velocity of the piston is zero and this velocity becomes maximum at the centre of each stroke and again becomes zero at the end of each stroke. Thus at the beginning of each stroke, the piston will be having an acceleration and at the end of each stroke, the piston will be having a retardation. The water in the cylinder is in contact with the piston and hence the water, flowing from the suction pipe or to the delivery pipe will have an acceleration at the beginning of each stroke and a retardation at the end of each stroke. This means the velocity of flow of water in the suction and delivery pipe will not be uniform. Hence, an accelerative or retarding head will be acting on the water flowing through the suction or delivery pipe. This accelerative or retarding head will change the pressure inside the cylinder.

If the ratio of length of connecting rod to the radius of crank (*i.e., L/r*) is very large, then the motion of the piston can be assumed as simple harmonic in nature. Fig. 20.3 shows the cylinder of a reciprocating single-acting pump, fitted with a piston which is connected to the crank. Let the crank is rotating at a constant angular speed.

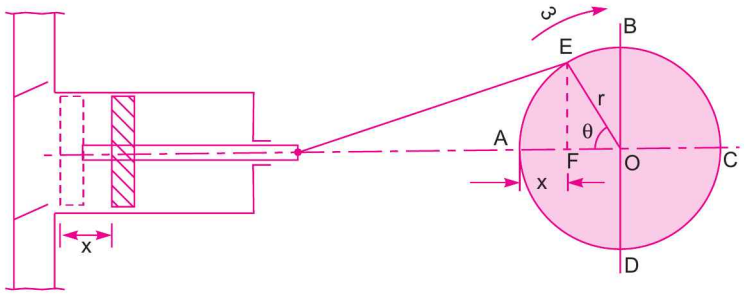

Fig. 20.3 *Velocity and acceleration of piston.*

Let ω = Angular speed of the crank in rad./s,

A = Area of the cylinder,

a = Area of the pipe (suction or delivery),

l = Length of the pipe (suction or delivery), and

r = Radius of the crank.

In the beginning, the crank is at A (which is called inner dead centre) and the piston in the cylinder is at a position shown by dotted lines. The crank is rotating with an angular velocity ω and let in time 't' seconds, the crank turns through an angle θ (in radians) from A (*i.e.*, inner dead centre). The displacement of the piston in time 't' is 'x' as shown in Fig. 20.3.

Now θ = Angle turned by crank in radians in time 't'

$= \omega t$ ...(*i*)

The distance x travelled by the piston is given as

x = Distance $AF = AO - FO$

$= r - r \cos \theta$ ($\because AO = r$, $FO = r \cos \theta$)

$= r - r \cos (\omega t)$ ($\because$ From (*i*), $\theta = \omega t$) ...(*ii*)

The velocity of the piston is obtained by differentiating equation (*ii*) with respect to 't' .

$\therefore$ Velocity of piston, $V = \dfrac{dx}{dt} = \dfrac{d}{dt}[r - r \cos (\omega t)]$

$= 0 - r [- \sin \omega t] \times \omega$ ($\because$ r is constant)

$= \omega r \sin \omega t.$ ...(20.10)

Now from continuity equation, the volume of water flowing into cylinder per second is equal to the volume of water flowing from the pipe per second.

$\therefore$ Velocity of water in cylinder $\times$ Area of cylinder

= Velocity of water in pipe $\times$ Area of pipe

or $V \times A = v \times a$ ($\because$ Velocity of water in cylinder = Velocity of piston = V)

where v = Velocity of water in pipe

$\therefore$ $v = \dfrac{V \times A}{a} = \dfrac{A}{a} \times V$

$= \dfrac{A}{a} \omega r \sin \omega t$ [$\because$ From (20.10), $V = \omega r \sin \omega t$] ...(20.11)

The acceleration of water in pipe is obtained by differentiating equation (20.11) with respect to *'t'*.

∴ Acceleration of water in pipe

$$= \frac{dv}{dt} = \frac{d}{dt}\left(\frac{A}{a}\omega r \sin \omega t\right) = \frac{A}{a}\omega^2 \, r \cos \omega t \qquad \text{....(20.12)}$$

Mass of water in pipe = ρ × Volume of water in pipe

= ρ × [Area of pipe × Length of pipe] = ρ × [$a \times l$] = ρal

∴ Force required to accelerate the water in the pipe

= Mass of water in pipe × Acceleration of water in pipe

$$= \rho al \times \frac{A}{a}\omega^2 \, r \cos \omega t$$

∴ Intensity of pressure due to acceleration

$$= \frac{\text{Force required to accelerate the water}}{\text{Area of pipe}}$$

$$= \frac{\rho al \times \frac{A}{a}\omega^2 r \cos \omega t}{a} = \rho l \times \frac{A}{a}\omega^2 r \cos \omega t$$

$$= \rho l \times \frac{A}{a}\omega^2 r \cos \theta \qquad (\because \ \omega t = \theta)$$

∴ Pressure head (h_a) due to acceleration

$$h_a = \frac{\text{Intensity of pressure due to acceleration}}{\text{Weight density of liquid}}$$

$$= \frac{\rho l \times \frac{A}{a}\omega^2 r \cos \theta}{\rho g} = \frac{l}{g} \times \frac{A}{a}\omega^2 r \cos \theta. \qquad \text{...(20.13)}$$

The pressure head due to acceleration in the suction and delivery pipes is obtained from equation (20.13) by using subscripts *'s'* and *'d'* as

$$h_{as} = \frac{l_s}{g} \times \frac{A}{a_s}\omega^2 r \cos \theta \qquad \text{...(20.14)}$$

$$h_{ad} = \frac{l_d}{g} \times \frac{A}{a_d}\omega^2 r \cos \theta. \qquad \text{...(20.15)}$$

The pressure head (h_a) due to acceleration, given by equation (20.13) varies with θ. The values of *'h_a'* for different values of θ are :

1. When θ = 0°, $h_a = \frac{l}{g} \times \frac{A}{a}\omega^2 r$ as cos 0° =1
2. When θ = 90°, $h_a = 0$ as cos 90° = 0
3. When θ = 180°, $h_a = -\frac{l}{g} \times \frac{A}{a}\omega^2 r$ as cos 180° = – 1

$\therefore$ Maximum pressure head due to acceleration

$$(h_a)_{max} = \frac{l}{g} \times \frac{A}{a} \omega^2 r \qquad ...(20.16)$$

▶ 20.7 EFFECT OF VARIATION OF VELOCITY ON FRICTION IN THE SUCTION AND DELIVERY PIPES

The velocity of water in suction or delivery pipe is given by equation (20.11) as

$$v = \frac{A}{a} \omega r \sin \omega t = \frac{A}{a} \omega r \sin \theta \qquad ...(i)$$

Loss of head due to friction in pipes is given by

$$h_f = \frac{4 f l v^2}{d \times 2g} \qquad ...(ii)$$

where f = Co-efficient of friction, l = Length of pipe,
d = Diameter of pipe, and v = Velocity of water in pipe.

Substituting equation (i) into equation (ii), we get

$$h_f = \frac{4 f l}{d \times 2g} \times \left[\frac{A}{a} \omega r \sin \theta\right]^2 \qquad ...(20.17)$$

The variation of h_f with θ is parabolic. The loss of head due to friction in suction and delivery pipes is obtained from equation (20.17) by using subscripts *'s'* for suction pipe and *'d'* for delivery pipe as

$$h_{fs} = \frac{4 f l_s}{d_s \times 2g} \times \left[\frac{A}{a_s} \omega r \sin \theta\right]^2 \qquad ...(20.18)$$

$$h_{fd} = \frac{4 f l_d}{d_d \times 2g} \times \left[\frac{A}{a_d} \omega r \sin \theta\right]^2 \qquad ... (20.19)$$

The loss of head due to friction in pipes given by equation (20.17) varies with θ as :

1. When $\theta = 0°$, $\sin \theta = 0$ $\therefore$ $h_f = \frac{4 f l}{d \times 2g} \times 0 = 0$

2. When $\theta = 90°$, $\sin 90° = 1$ $\therefore$ $h_f = \frac{4 f l}{d \times 2g} \times \left[\frac{A}{a} \omega r\right]^2$

3. When $\theta = 180°$, $\sin 180° = 0$ $\therefore$ $h_f = 0$

$\therefore$ Maximum value of loss of head due to friction ;

$$(h_f)_{max} = \frac{4 f l}{d \times 2g} \times \left[\frac{A}{a} \omega r\right]^2 \qquad ...(20.20)$$

Problem 20.3 *The cylinder bore diameter of a single-acting reciprocating pump is 150 mm and its stroke is 300 mm. The pump runs at 50 r.p.m. and lifts water through a height of 25 m. The delivery pipe is 22 m long and 100 mm in diameter. Find the theoretical discharge and the theoretical power required to run the pump. If the actual discharge is 4.2 litres/s, find the percentage slip. Also determine the acceleration head at the beginning and middle of the delivery stroke.*

Solution. Given :

Dia. of cylinder, $D = 150 \text{ mm} = 0.15 \text{ m}$

$\therefore$ Area, $A = \left(\frac{\pi}{4}\right) \times 0.15^2 = 0.01767 \text{ m}^2$

Stroke, $L = 300 \text{ mm} = 0.3 \text{ m}$

Speed of pump, $N = 50$ r.p.m.

Total height through which water is lifted,

$H = 25 \text{ m}$

Length of delivery pipe, $l_d = 22 \text{ m}$

Diameter of delivery pipe, $d_d = 100 \text{ mm} = 0.1 \text{ m}$

Actual discharge, $Q_{act} = 4.2 \text{ litres/s} = \frac{4.2}{1000} \text{ m}^3/\text{s} = 0.0042 \text{ m}^3/\text{s}.$

(*i*) *Theoretical discharge* (Q_{th})

Theoretical discharge for a single-acting reciprocating pump is given by equation (20.1), as

$$Q_{th} = \frac{A \times L \times N}{60} = \frac{0.01767 \times 0.3 \times 50}{60} = 0.0044175 \text{ m}^3/\text{s}$$

$$= 0.0044175 \times 1000 \text{ litres/s} = \mathbf{4.4175 \text{ litres/s. Ans.}}$$

(*ii*) *Theoretical power* (P_t)

Theoretical power is given by, $P_t = \frac{(\text{Theoretical weight of water lifted/s}) \times \text{Total height}}{1000}$

$$= \frac{\rho \times g \times Q_{th} \times H}{1000}$$

$$= \frac{1000 \times 9.81 \times 0.0044175 \times 25}{1000} \qquad \left(\because Q_{th} = 0.0044175 \text{ m}^3/\text{s}\right)$$

$$= \mathbf{1.0833 \text{ kW. Ans.}}$$

(*iii*) *The percentage slip*

The percentage slip is given by,

$$\% \text{ slip} = \left(\frac{Q_{th} - Q_{act}}{Q_{th}}\right) \times 100 = \left(\frac{4.4175 - 4.2}{4.4175}\right) \times 100 = \mathbf{4.92\%. \text{ Ans.}}$$

(*iv*) *Acceleration head at the beginning of delivery stroke.*

The acceleration head in the delivery pipe is given by equation (20.15) as :

$$h_{ad} = \frac{l_d}{g} \times \frac{A}{a_d} \omega^2 r \times \cos\theta$$

where a_d = Area of delivery pipe $= \frac{\pi}{4} \times (0.1)^2 = 0.007854$

$$\omega = \text{Angular speed} = \frac{2\pi N}{60} = \frac{2\pi \times 50}{60} = 5.236$$

$$r = \text{Crank radius} = \frac{L}{2} = \frac{0.3}{2} = 0.15 \text{ m}$$

$$\therefore \quad h_{ad} = \frac{22}{9.81} \times \frac{0.01767}{0.007854} \times 5.236^2 \times 0.15 \times \cos\theta = 20.75 \times \cos\theta$$

At the beginning of delivery stroke, $\theta = 0°$ and hence $\cos\theta = 1$

$$\therefore \quad h_{ad} = \mathbf{20.75\ m.\ Ans.}$$

(*v*) *Acceleration head at the middle of delivery stroke.*

At the middle of delivery stroke, $\theta = 90°$ and hence $\cos\theta = 0$.

$$\therefore \quad h_{ad} = 20.75 \times 0 = \mathbf{0.\ Ans.}$$

▶ 20.8 INDICATOR DIAGRAM

The indicator diagram for a reciprocating pump is defined as the graph between the pressure head in the cylinder and the distance travelled by piston from inner dead centre for one complete revolution of the crank. As the maximum distance travelled by the piston is equal to the stroke length and hence the indicator diagram is a graph between pressure head and stroke length of the piston for one complete revolution. The pressure head is taken as ordinate and stroke length as abscissa.

20.8.1 Ideal Indicator Diagram. The graph between pressure head in the cylinder and stroke length of the piston for one complete revolution of the crank under ideal conditions is known as ideal indicator diagram. Fig. 20.4 shows the ideal indicator diagram, in which line *EF* represents the atmospheric pressure head equal to 10.3 m of water.

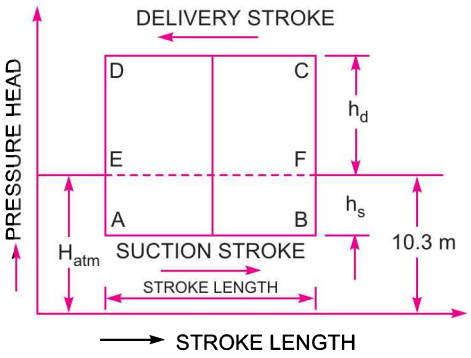

Fig. 20.4 *Ideal indicator diagram.*

Let H_{atm} = Atmospheric pressure head
= 10.3 m of water,
L = Length of the stroke,
h_s = Suction head, and
h_d = Delivery head.

During suction stroke, the pressure head in the cylinder is constant and equal to suction head (h_s), which is below the atmospheric pressure head (H_{atm}) by a height of h_s. The pressure head during suction stroke is represented by a horizontal line *AB* which is below the line *EF* by a height of 'h_s'.

During delivery stroke, the pressure head in the cylinder is constant and equal to delivery head (h_d), which is above the atmospheric head by a height of (h_d). Thus, the pressure head during delivery stroke is represented by a horizontal line *CD* which is above the line *EF* by a height of h_d. Thus, for one complete revolution of the crank, the pressure head in the cylinder is represented by the diagram *A-B-C-D-A*. This diagram is known as ideal indicator diagram.

Now from equation (20.3), we know that the work done by the pump per second

$$= \frac{\rho \times g \times ALN}{60} \times (h_s + h_d)$$

$$= K \times L(h_s + h_d) \qquad \left(\text{where } K = \frac{\rho g AN}{60} = \text{Constant}\right)$$

$$\propto L \times (h_s + h_d) \qquad \ldots(i)$$

But from Fig. 20.4, area of indicator diagram

$$= AB \times BC = AB \times (BF + FC) = L \times (h_s + h_d).$$

Substituting this value in equation (i), we get

Work done by pump $\propto$ Area of indicator diagram. ...(20.21)

20.8.2 Effect of Acceleration in Suction and Delivery Pipes on Indicator Diagram. The pressure head due to acceleration in the suction pipe is given by equation (20.14) as

$$h_{as} = \frac{l_s}{g} \times \frac{A}{a_s} \omega^2 r \cos\theta$$

When $\theta = 0°$, $\cos\theta = 1$, and $h_{as} = \frac{l_s}{g} \times \frac{A}{a_s} \omega^2 r$

When $\theta = 90°$, $\cos\theta = 0$, and $h_{as} = 0$

When $\theta = 180°$, $\cos\theta = -1$, and $h_{as} = -\frac{l_s}{g} \times \frac{A}{a_s} \omega^2 r$.

Thus, the pressure head inside the cylinder during suction stroke will not be equal to 'h_s', as was the case for ideal indicator diagram, but it will be equal to the sum of 'h_s' and 'h_{as}'. At the beginning of suction stroke $\theta = 0°$, 'h_{as}' is +ve and hence the pressure head in the cylinder will be ($h_s + h_{as}$) below the atmospheric pressure head. At the middle of suction stroke $\theta = 90°$ and $h_{as} = 0$ and hence pressure head in the cylinder will be h_s below the atmospheric pressure head. At the end of suction stroke, $\theta = 180°$ and h_{as} is –ve and hence the pressure head in the cylinder will be ($h_s - h_{as}$) below the atmospheric pressure head. For suction stroke, the indicator diagram will be shown by $A'GB'$. Also the area of $A'AG$ = Area of BGB'.

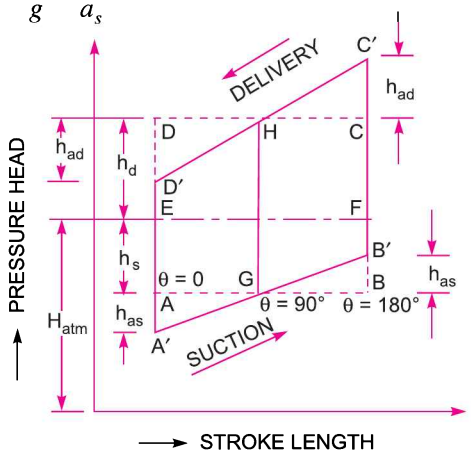

Fig. 20.5 *Effect of acceleration on indicator diagram.*

Similarly, the indicator diagram for the delivery stroke can be drawn. At the beginning of delivery stroke, h_{ad} is +ve and hence the pressure head in the cylinder will be ($h_d + h_{ad}$) above the atmospheric pressure head. At the middle of the delivery stroke, $h_{ad} = 0$ and hence pressure head in the cylinder is equal to h_d above the atmospheric pressure head. At the end of the delivery stroke, h_{ad} is –ve and hence pressure in the cylinder will be ($h_d - h_{ad}$) above the atmospheric pressure head. And thus the indicator diagram for delivery stroke is represented by the line $C'HD'$. Also, the area of $CC'H$ = Area of $DD'H$.

From Fig. 20.5, it is now clear that due to acceleration in suction and delivery pipe, the indicator diagram has changed from $ABCD$ to $A'B'C'D'$. But the area of indicator diagram $ABCD$ = Area $A'B'C'D'$. Now from equation (20.21), work done by pump is proportional to the area of indicator diagram. Hence the work done by the pump on the water remains same.

Problem 20.4 *The length and diameter of a suction pipe of a single-acting reciprocating pump are 5 m and 10 cm respectively. The pump has a plunger of diameter 15 cm and a stroke length of 35 cm. The centre of the pump is 3 m above the water surface in the pump. The atmospheric pressure head is 10.3 m of water and pump is running at 35 r.p.m. Determine :*

(*i*) *Pressure head due to acceleration at the beginning of the suction stroke,*
(*ii*) *Maximum pressure head due to acceleration, and*
(*iii*) *Pressure head in the cylinder at the beginning and at the end of the stroke.*

Solution. Given :

Length of suction pipe, $l_s = 5$ m

Diameter of suction pipe, $d_s = 10$ cm $= 0.1$ m

$\therefore$ Area, $a_s = \frac{\pi}{4} d_s^2 = \frac{\pi}{4} \times 0.1^2 = .007854 \text{ m}^2$

Diameter of plunger, $D = 15$ cm $= 0.15$ m

$\therefore$ Area of plunger, $A = \frac{\pi}{4} D^2 = \frac{\pi}{4} \times .15^2 = .01767 \text{ m}^2$

Stroke length, $L = 35$ cm $= 0.35$ m

$\therefore$ Crank radius, $r = \frac{L}{2} = \frac{0.35}{2} = 0.175$ m

Suction head, $h_s = 3$ m

Atmospheric pressure head, $H_{atm} = 10.3$ m of water

Speed of pump, $N = 35$ r.p.m.

Angular speed of the crank is given by,

$$\omega = \frac{2\pi N}{60} = \frac{2\pi \times 35}{60} = 3.665 \text{ rad/s.}$$

(*i*) The pressure head due to acceleration in the suction pipe is given by equation (20.14) as

$$h_{as} = \frac{l_s}{g} \times \frac{A}{a_s} \times \omega^2 r \cos\theta$$

At the beginning of stroke, $\theta = 0^o$ and hence $\cos\theta = 1$

$\therefore$ $$h_{as} = \frac{l_s}{g} \times \frac{A}{a_s} \times \omega^2 r = \frac{5}{9.81} \times \frac{.01767}{.007854} \times 3.665^2 \times .175 = \mathbf{2.695 \text{ m. Ans.}}$$

(*ii*) Maximum pressure head due to acceleration in suction pipe is given by equation (20.16), as

$$(h_{as})_{\max} = \frac{l_s}{g} \times \frac{A}{a_s} \times \omega^2 r = \mathbf{2.695 \text{ m. Ans.}}$$

(*iii*) Pressure head in the cylinder at the beginning of the suction stroke (Refer to Fig. 20.5)

$= h_s + h_{as} = 3.0 + 2.695 = 5.695.$

This pressure head in the cylinder is below the atmospheric pressure head.

$\therefore$ Absolute pressure head in the cylinder at the beginning of suction stroke

= Atmospheric pressure head – 5.695

= 10.3 – 5.695 = **4.605 m of water (abs.) Ans.**

Similarly, pressure head in the cylinder at the end of suction stroke

$= h_s - h_{as} = 3.0 - 2.695 = 0.305$ m below atmospheric pressure head

= 10.3 – 0.305 = **9.995 m of water (abs.) Ans.**

Problem 20.5 *If in Problem 20.4, the length and diameter of the delivery pipe are 30 m and 10 cm respectively and water is delivered by the pump to a tank which is 20 m above the centre of the pump, determine :*

(*i*) *Pressure head due to acceleration at the beginning of delivery stroke,*

(*ii*) *Pressure head in the cylinder at the beginning of the delivery stroke, and*

(*iii*) *Pressure head in the cylinder at the end of the delivery stroke.*

Solution. Given :

Length of delivery pipe, $l_d = 30$ m

Diameter of delivery pipe, $d_d = 10$ cm $= 0.1$ m

$\therefore$ Area of delivery pipe, $a_d = \frac{\pi}{4} d_d^2 = \frac{\pi}{4}(.1)^2 = .007854 \text{ m}^2$

Diameter of plunger, $D = 15$ cm $= 0.15$ m

$\therefore$ Area of plunger, $A = \frac{\pi}{4} D^2 = \frac{\pi}{4}(.15)^2 = .01767 \text{ m}^2$

Stroke length, $L = 35$ cm $= 0.35$ m

Crank radius, $r = \frac{L}{2} = \frac{0.35}{2} = 0.175$ m

Delivery head, $h_d = 20$ m

Speed of pump, $N = 35$ r.p.m.

Angular speed, $\omega = \frac{2\pi N}{60} = \frac{2\pi \times 35}{60} = 3.665$ rad/s.

(*i*) Using equation (20.15), we get the pressure head due to acceleration in delivery pipe as

$$h_{ad} = \frac{l_d}{g} \times \frac{A}{a_d} \omega^2 r \cos\theta$$

At the beginning of delivery stroke, $\theta = 0^\circ$ and hence $\cos\theta = 1$.

$\therefore$ Pressure head due to acceleration at the beginning of delivery stroke becomes as

$$h_{ad} = \frac{l_d}{g} \times \frac{A}{a_d} \omega^2 r$$

$$= \frac{30}{9.81} \times \frac{.01767}{.007854} \times (3.665)^2 \times 0.175 = \mathbf{16.17 \text{ m. Ans.}}$$

(*ii*) From Fig. 20.5, the pressure head in the cylinder at the beginning of the delivery stroke

$= FC' = FC + CC' = (h_d + h_{ad})$ m of water above atmospheric head

$= 20 + 16.17 = 36.17$ m of water above atms.

$= 36.17 +$ Atmospheric pressure head

$= 36.17 + 10.3 =$ **46.47 m (abs.) Ans.**

(*iii*) The pressure head in the cylinder at the end of delivery stroke

$= ED'$ above atmospheric pressure head

$= (ED - DD') = (h_d - h_{ad})$

$= 20 - 16.17 = 3.83$ m of water above atms.

$= 3.83 + 10.3 =$ **14.13 m (abs.) Ans.**

Problem 20.6 *A single-acting reciprocating pump has piston diameter 12.5 cm and stroke length 30 cm. The centre of the pump is 4 m above the water level in the sump. The diameter and length of suction pipe are 7.5 cm and 7 m respectively. The separation occurs if the absolute pressure head in the cylinder during suction stroke falls below 2.5 m of water. Calculate the maximum speed at which the pump can run without separation. Take atmospheric pressure head = 10.3 m of water.*

Solution. Given :

Diameter of piston, $D = 12.5 \text{ cm} = 0.125 \text{ m}$

$\therefore$ Area, $A = \frac{\pi}{4}(.125)^2 = .01227 \text{ m}^2$

Stroke length, $L = 30 \text{ cm} = 0.30 \text{ m}$

$\therefore$ Crank radius, $r = \frac{L}{2} = \frac{0.30}{2} = 0.15 \text{ m}$

Suction head, $h_s = 4.0 \text{ m}$

Diameter of suction pipe, $d_s = 7.5 \text{ cm} = 0.075 \text{ m}$

$\therefore$ Area of suction pipe, $a_s = \frac{\pi}{4}(.075)^2 = .004418 \text{ m}^2$

Length of suction pipe, $l_s = 7.0 \text{ m}$

Separation pressure head, $h_{sep} = 2.5 \text{ m (absolute)}$

Atmospheric pressure head, $H_{atm} = 10.3 \text{ m}$

From the indicator diagram, drawn in Fig. 20.5, it is clear that the absolute pressure head during suction stroke is minimum at the beginning of the stroke. Thus, the separation can take place at the beginning of the stroke only. In that case the pressure head in the cylinder at the beginning of stroke becomes = h_{sep}.

But pressure head in the cylinder at the beginning of suction stroke

$= (h_s + h_{as})$ m below atmospheric pressure head

$=$ Atmospheric pressure head $- (h_s + h_{as})$ m absolute

$= H_{atm} - (h_s + h_{as})$ m (abs.)

$= 10.3 - (4.0 + h_{as})$

$\therefore$ $h_{sep} = 10.3 - (4.0 + h_{as})$

$2.5 = 10.3 - 4.0 - h_{as}$

or $h_{as} = 10.3 - 4.0 - 2.5 = 3.80 \text{ m}.$ ...(*i*)

But from equation (20.14), h_{as} at the beginning of suction stroke is given by the relation

$$h_{as} = \frac{l_s}{g} \times \frac{A}{a_s} \omega^2 r \qquad (\because \theta = 0^\circ, \because \cos\theta = 1) \text{ ...(}ii\text{)}$$

Equating equations (*i*) and (*ii*), we get

$$3.80 = \frac{l_s}{g} \times \frac{A}{a_s} \times \omega^2 r = \frac{7.0}{9.81} \times \frac{.01227}{.004418} \times \omega^2 \times .15$$

$\therefore$ $$\omega^2 = \frac{3.80 \times 9.81 \times .004418}{7.0 \times .01227 \times .15} = 12.783$$

or $\omega = \sqrt{12.783} = 3.575 \text{ radian/s}.$

But $\omega = \frac{2\pi N}{60}$

$$\therefore \quad N = \frac{60 \times \omega}{2\pi} = \frac{60 \times 3.575}{2\pi} = \textbf{34.14 r.p.m. Ans.}$$

Thus, the maximum speed at which the pump can run without separation is 34.14 r.p.m.

Problem 20.7 *The diameter and stroke length of a single-acting reciprocating pump are 100 mm and 300 mm respectively. The water is lifted to a height of 20 m above the centre of the pump. Find the maximum speed at which the pump may be run so that no separation occurs during the delivery stroke if the diameter and length of delivery pipe are 50 mm and 25 m respectively. Separation occurs if the absolute pressure head in the cylinder during delivery stroke falls below 2.50 m of water.*

Take atmospheric pressure head = 10.3 m of water.

Solution. Given :

Diameter of pump, $D = 100$ mm $= 0.1$ m

Stroke length , $L = 300$ mm $= 0.30$ m

$\therefore$ Crank radius, $r = \frac{L}{2} = \frac{0.30}{2} = 0.15$ m

Delivery head, $h_d = 20$ m

Diameter of delivery pipe, $d_d = 50$ mm $= 0.05$ m

Length of delivery pipe, $l_d = 25$ m

Separation pressure head, $h_{sep} = 2.5$ m (abs.)

Atmospheric pressure head, $H_{atm} = 10.3$ m of water.

Fig. 20.6 show the indicator diagram for delivery stroke only. The absolute pressure head during delivery stroke is minimum at the end of the stroke only. It means, if separation is to take place, it will occur only at the end of the delivery stroke where pressure head will be equal to separation pressure head (h_{sep}). The absolute pressure head at the end of delivery stroke from Fig. 20.6 is equal to $D'M$.

where $D'M = DM - DD'$

$= (DE + EM) - DD' \quad (\because DM = DE + EM)$

$= (h_d + H_{atm}) - h_{ad}$

$\therefore \quad h_{sep} = (h_d + H_{atm}) - h_{ad}$

or $\quad 2.5 = (20 + 10.3) - h_{ad}$

$\therefore \quad h_{ad} = (20 + 10.3) - 2.5 = 27.8$ m

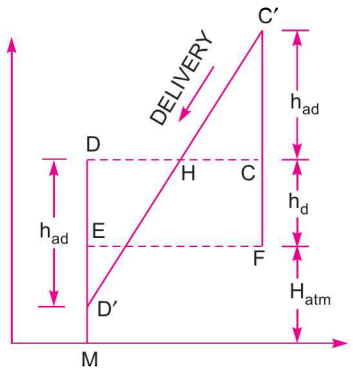

Fig. 20.6

But the acceleration head (h_{ad}) at the end of delivery stroke is given by

$$h_{ad} = \frac{l_d}{g} \times \frac{A}{a_d} \times \omega^2 r$$

$$27.8 = \frac{25}{9.81} \times \frac{\frac{\pi}{4}D^2}{\frac{\pi}{4}d_d^2} \times \omega^2 \times 0.15 = \frac{25}{9.81} \times \frac{D^2}{d_d^2} \times \omega^2 \times .15$$

$$= \frac{25}{9.81} \times \left(\frac{0.1}{.05}\right)^2 \times \omega^2 \times .15 = 1.529\omega^2$$

$$\therefore \quad \omega = \sqrt{\frac{27.8}{1.529}} = 4.264 \text{ radians/s.}$$

But we know, $\omega = \dfrac{2\pi N}{60}$

$\therefore$ $H = \dfrac{60 \times \omega}{2\pi} = \dfrac{60 \times 4.264}{2\pi} =$ **40.72 r.p.m. Ans.**

Problem 20.8 *A single-acting reciprocating pump raises water to a height of 20 m through a delivery pipe 35 m long and 140 mm in diameter. The bore and stroke of piston are 250 mm and 400 mm respectively. Cavitation occurs at 2.5 m of water absolute. Find the speed at which the pump can run without separation on delivery side if the pipe rises first vertically and then runs horizontally. Will there be any change in the maximum speed if the pipe first runs horizontally and then rises vertically.*

Solution. Given :

Delivery head, $h_d = 20$ m

Length of delivery pipe, $l_d = 35$ m

Dia. of delivery pipe, $d_d = 140$ mm $= 0.14$ m

Dia. of piston, $D = 250$ mm $= 0.25$ m

Stroke length, $L = 400$ mm $= 0.40$ m

$\therefore$ Crank radius, $r = \dfrac{L}{2} = \dfrac{0.40}{2} = 0.20$ m

Separation pressure head, $h_{sep} = 2.5$ m (abs.)

Atmospheric pressure head, $H_{atm} = 10.3$ m

The separation on delivery side can occur only at the end of delivery stroke as the pressure head during delivery stroke is minimum at the end of delivery stroke only. The acceleration head (h_{ad}) at the end of delivery stroke is given by,

$$h_{ad} = \frac{l_d}{g} \times \frac{A}{a_d} \times \omega^2 r = \frac{35}{9.81} \times \frac{\frac{\pi}{4} D^2}{\frac{\pi}{4} d_d^2} \times \omega^2 \times 0.20$$

$$= \frac{35}{9.81} \times \frac{0.25^2}{0.14^2} \times \omega^2 \times 0.20.$$

1st Case. The pipe rises first vertically and then horizontally as shown in Fig. 20.6 (*a*). In this case, the possibility of separation is at the point *C* at the end of the delivery stroke.

The pressure head at the end of delivery stroke at *B* will be equal to atmospheric pressure head plus delivery head minus acceleration head.

$\therefore$ Pressure head at $B = H_{atm} + h_d - h_{ad}$

The pressure head at *C* = Pressure head at $B - h_d$

$$= (H_{atm} + h_d - h_{ad}) - h_d = H_{atm} - h_{ad}$$

Now if separation is to take place at *C*, then the pressure head at *C* is 2.5 m.

Equating the two pressure heads at *C*, we get

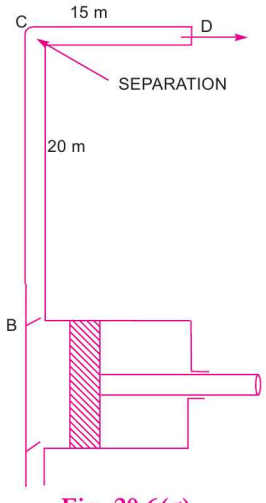

Fig. 20.6(*a*)

$$2.5 = H_{atm} - h_{ad}$$

or $$h_{ad} = H_{atm} - 2.5 = 10.3 - 2.5 = 7.8 \text{ m}$$

or $$\frac{35}{9.81} \times \frac{0.25^2}{0.14^2} \times \omega^2 \times 0.20 = 7.8$$

or $$\omega = \sqrt{\frac{9.81 \times 0.14^2 \times 7.8}{35 \times 0.25^2 \times 0.20}} = 1.85 \text{ rad/s}$$

$\therefore$ $$N = \frac{60 \times \omega}{2\pi} = \frac{60 \times 1.85}{2\pi} = \textbf{17.68 r.p.m. Ans.}$$

2nd Case. The pipe first runs horizontally and then rises vertically as shown in Fig. 20.6 (*b*).

In this case, the possibility of separation is at the point *C* at the end of delivery stroke. But the pressure head at *C* is same as pressure head at *B* and *C* are in the horizontal plane. Hence, at the end of delivery stroke, the pressure head at *B* is equal to $H_{atm} + h_d - h_{ad}$.

For this condition

$$h_{sep} = H_{atm} + h_d - h_{ad}$$

or $$2.5 = 10.3 + 20 - h_{ad}$$

or $$h_{ad} = 10.3 + 20 - 2.5 = 27.8$$

or $$\frac{35}{9.81} \times \frac{0.25^2}{0.14^2} \times \omega^2 \times 0.20 = 27.8$$

or $$\omega = \sqrt{\frac{9.81 \times 0.14^2 \times 27.8}{35 \times 0.25^2 \times 0.20}} = 3.495$$

$\therefore$ $$N = \frac{60 \times \omega}{2\pi} = \frac{60 \times 3.495}{2\pi}$$

$$= \textbf{33.37 r.p.m. Ans.}$$

$\therefore$ Change in maximum speed

$$= 33.36 - 17.68 = \textbf{15.69 r.p.m. Ans.}$$

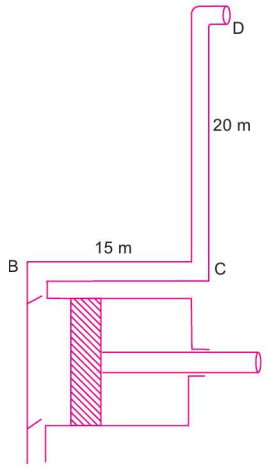

Fig. 20.6(*b*)

Problem 20.9 *A single-acting reciprocating pump has a plunger of 10 cm diameter and a stroke of length 200 mm. The centre of the pump is 4 m above the water level in the sump and 14 m below the level of water in a tank to which water is delivered by the pump. The diameter and length of suction pipe are 40 mm and 6 m while of the delivery pipe are 30 mm and 18 m respectively. Determine the maximum speed at which the pump may be run without separation, if separation occurs at 7.848 N/cm^2 below the atmospheric pressure. Take atmospheric pressure head = 10.3 m of water.*

Solution. Given :

Diameter of plunger, $D = 100 \text{ mm} = 0.10 \text{ m}$

Stroke length, $L = 200 \text{ mm} = 0.20 \text{ m}$

$\therefore$ Crank radius, $$r = \frac{L}{2} = \frac{0.20}{2} = 0.10 \text{ m}$$

Suction head, $h_s = 4 \text{ m}$

Delivery head, $h_d = 14 \text{ m}$

Dia. of suction pipe, $d_s = 40 \text{ mm} = 0.04 \text{ m}$

Length of suction pipe, $l_s = 6 \text{ m}$

Dia. of delivery pipe, $d_d = 30 \text{ mm} = .03 \text{ m}$

Length of delivery pipe, $l_d = 18 \text{ m}$

Separation pressure, $p_{sep} = \dfrac{7.848\,N}{\text{cm}^2} = \dfrac{7.848 \times 10^4}{\text{m}^2}$

$\therefore$ Separation pressure head, $h_{sep} = \dfrac{p_{sep}}{\rho g} = \dfrac{7.848 \times 10^4}{1000 \times 9.81} = 8.0$ m below atmosphere

$= (H_{atm} - 8.0)$ absolute $= (10.3 - 8.0) = 2.3$ m (abs.)

where H_{atm} = Atmospheric pressure head = 10.3 m.

(*i*) **Speed of pump without separation during suction stroke.** During suction stroke, possibility of separation is only at the beginning of the stroke. The pressure head in the cylinder at the beginning of suction stroke

$= (h_s + h_{as})$ m below atmospheric pressure head

$= 10.3 - (h_s + h_{as})$ m (abs.)

$\therefore \quad h_{sep} = 10.3 - (h_s + h_{as})$

or $\quad 2.3 = 10.3 - (h_s + h_{as}) = 10.3 - 4 - h_{as}$

$\therefore \quad h_{as} = 10.3 - 4 - 2.3 = 4$ m. ...(*i*)

But 'h_{as}' at the beginning of suction stroke is given by,

$$h_{as} = \frac{l_s}{g} \times \frac{A}{a_s} \times \omega^2 r = \frac{6}{9.81} \times \frac{\frac{\pi}{4} D^2}{\frac{\pi}{4} d_s^2} \times \omega^2 \times .10$$

$$= \frac{6}{9.81} \times \left(\frac{0.1}{.04}\right)^2 \times \omega^2 \times .1 = 0.3822\,\omega^2 \qquad ...(ii)$$

Equating the values of h_{as} given by equations (*i*) and (*ii*),

$$4 = 0.3822\,\omega^2$$

$\therefore \quad \omega = \sqrt{\dfrac{4}{.382}} = 3.235$ rad/s

But ω is also $= \dfrac{2\pi N}{60}$

$\therefore \quad N = \dfrac{60 \times \omega}{2\pi} = \dfrac{60 \times 3.235}{2\pi} = 30.89$ r.p.m.

$\therefore$ Maximum speed of the pump without separation during suction stroke only is 30.89 r.p.m.

(*ii*) **Speed of pump without separation during delivery stroke.** During delivery stroke, the possibility of separation is only at the end of the delivery stroke. The pressure head in the cylinder at the end of the delivery stroke from Fig. 20.6

$$= (H_{atm} + h_d) - h_{ad} \text{ m (abs.)} = (10.3 + 14) - h_{ad.}$$

If separation is to be avoided this pressure should be equal to separation pressure head.

$$\therefore \quad h_{sep} = (10.3 + 14) - h_{ad} \text{ or } 2.30 = (10.3 + 14) - h_{ad}$$

$$\therefore \quad h_{ad} = 10.3 + 14.0 - 2.30 = 22.0 \text{ m}$$

But 'h_{ad}' is given by the relation

$$h_{ad} = \frac{l_d}{g} \times \frac{A}{a_d} \times \omega^2 \times r$$

$$\therefore \quad 22.0 = \frac{18.0}{9.81} \times \frac{\frac{\pi}{4} D^2}{\frac{\pi}{4} d_d^2} \times \omega^2 \times r = \frac{18.0}{9.81} \times \frac{D^2}{d_d^2} \times \omega^2 \times r$$

$$= \frac{18.0}{9.81} \times \left(\frac{.1}{.03}\right)^2 \times \omega^2 \times 0.10 = 2.04\ \omega^2$$

$$\therefore \quad \omega = \sqrt{\frac{22.0}{2.04}} = 3.284 \text{ rad/s.}$$

But $$\omega = \frac{2\pi N}{60}$$

$$\therefore \quad N = \frac{60 \times \omega}{2\pi} = \frac{60 \times 3.284}{2 \times \pi} = 31.36 \text{ r.p.m.}$$

$\therefore$ Maximum speed of the pump without separation during delivery stroke is 31.36 r.p.m.

Thus the maximum speed of the pump without separation during suction and delivery stroke is the minimum of these two speeds, *i.e.*, minimum of 30.89 and 31.36 r.p.m.

$\therefore$ Maximum speed = **30.89 r.p.m. Ans.**

20.8.3 Effect of Friction in Suction and Delivery Pipes on Indicator Diagram. The loss of head due to friction in suction and delivery pipes is given by equations (20.18) and (20.19) as

$$h_{fs} = \frac{4 f l_s}{d_s \times 2g} \times \left(\frac{A}{a_s} \omega r \sin\theta\right)^2 \text{ and } h_{fd} = \frac{4 f l_d}{d_d \times 2g} \times \left(\frac{A}{a_d} \omega r \sin\theta\right)^2$$

It is clear from the above equations that the variation of h_{fs} or h_{fd} is parabolic with θ.

During the suction or delivery stroke, the pressure head inside the cylinder will change as given below :

(*i*) At the beginning of the suction or delivery stroke, $\theta = 0°$ and hence $\sin\theta = 0$. This means h_{fs} and $h_{fd} = 0$.

(*ii*) At the middle of the suction or delivery stroke, $\theta = 90°$ and hence $\sin\theta = 1$. This means

$$h_{fs} = \frac{4 f l_s}{d_s \times 2g} \times \left(\frac{A}{a_s} \omega r\right)^2 \text{ and } h_{fd} = \frac{4 f l_d}{d_d \times 2g} \times \left(\frac{A}{a_d} \omega r\right)^2.$$

(*iii*) At the end of the suction or delivery stroke, $\theta = 180°$ and hence $\sin\theta = 0°$. This means h_{fs} and $h_{fd} = 0$.

As the variation of h_{fs} or h_{fd} with θ is parabolic in nature, the indicator diagram during suction and delivery stroke with friction in suction pipe and delivery pipe will be as shown in Fig. 20.7.

The area of the parabolas *AGB* and *CHD* represents the work done against friction in suction and delivery pipes.

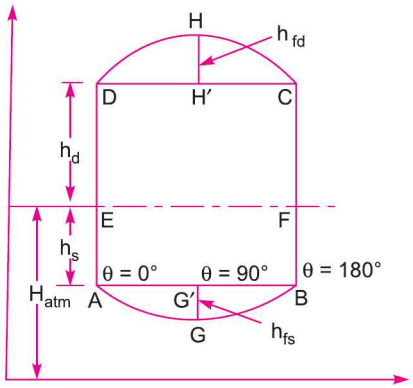

Fig. 20.7 *Effect of friction on indicator diagram.*

Now $$\text{area } AGB = AB \times \frac{2}{3} GG'$$

$$= AB \times \frac{2}{3} h_{fs} = L \times \frac{2}{3} h_{fs}$$

where $$h_{fs} = \frac{4 \times f \times l_s}{d_s \times 2g} \times \left(\frac{A}{a_s}\omega r\right)^2$$

Similarly, $$\text{area } CHD = CD \times \frac{2}{3} \times HH' = CD \times \frac{2}{3} h_{fd}$$

$$= L \times \frac{2}{3} h_{fd} \qquad (\because \quad CD = L = \text{Length of stroke})$$

where $$h_{fd} = \frac{4 f l_d}{d_d \times 2g} \times \left(\frac{A}{a_d}\omega r\right)^2.$$

20.8.4 Effect of Acceleration and Friction in Suction and Delivery Pipes on Indicator Diagram. Fig. 20.8 shows the combined effect of acceleration and friction in suction and delivery pipes. The pressure head in the cylinder during suction and delivery strokes will change as given below :

(*i*) At the beginning of the suction stroke, $\theta = 0°$ and hence h_{as} from equation (20.14) is equal to $\frac{l_s}{g} \times \frac{A}{a_s}\omega^2 r$. But $h_{fs} = 0$. Thus, the pressure head in the cylinder will be $(h_s + h_{as})$ below the atmospheric pressure head.

(*ii*) At the middle of the suction stroke, $h_{as} = 0$ but $h_{fs} = \frac{4 \times f \times l_s}{d_s \times 2g} \times \left(\frac{A}{a_s}\omega r\right)^2$. Thus, the pressure head in the cylinder will be $(h_s + h_{fs})$ below the atmospheric pressure head.

(*iii*) At the end of the suction stroke, $h_{as} = -\frac{l_s}{g} \times \frac{A}{a_s}\omega^2 r$ but $h_{fs} = 0$. Thus, the pressure head in the cylinder will be $(h_s - h_{as})$ below the atmospheric pressure head.

(*iv*) At the beginning of the delivery stroke, $h_{ad} = -\frac{l_d}{g} \times \frac{A}{a_d} \times \omega^2 r$ but $h_{fd} = 0$. Thus, the pressure head in the cylinder will be $(h_d + h_{ad})$ above the atmospheric pressure head.

(*v*) In the middle of the delivery stroke, $h_{ad} = 0$ and $h_{fd} = \frac{4 f l_d}{d_d \times 2g} \times \left(\frac{A}{a_d}\omega r\right)^2$. Thus the pressure head in the cylinder will be $(h_d + h_{fd})$ above the atmospheric pressure head.

(*vi*) At the end of the delivery stroke, $h_{ad} = -\frac{l_d}{g} \times \frac{A}{a_d} \times \omega^2 r$ and $h_{fd} = 0$. Thus, the pressure head in the cylinder will be $(h_d - h_{ad})$ above the atmospheric pressure head.

Thus, the indicator diagram with acceleration and friction in suction and delivery pipes will become as shown in Fig. 20.8.

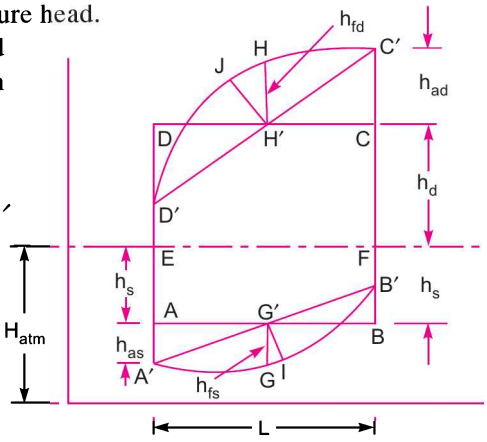

Fig. 20.8 *Effect of acceleration and friction on indicator diagram.*

Area of the indicator diagram $A'GB'\ C'HD'$

= Area of $A'G'B'C'H'D'$ + Area of parabola $A'GB'$ + Area of parabola $C'HD'$

But area of $A'G'B'C'H'D'$

= Area of $ABCD$

$= (h_s + h_d) \times L$

Area of parabola $A'GB'$

$$= A'B' \times \frac{2}{3} \times G'I = \frac{2}{3} \times (A'B' \times G'I)$$

$$= \frac{2}{3} \times (AB \times GG') = \frac{2}{3} \times L' h_{fs}$$

Similarly, area of parabola $C'HD'$

$$= C'D' \times \frac{2}{3} H'J = \frac{2}{3} (C'D' \times H'J)$$

$$= \frac{2}{3} \times (CD \times H'H) = \frac{2}{3}(L \times h_{fd}) = \frac{2}{3} L \times h_{fd}$$

$\therefore$ Area of indicator diagram

$$= (h_s + h_d) \times L + \frac{2}{3} \times L \times h_{fs} + \frac{2}{3} \times L \times h_{fd}$$

$$= \left(h_s + h_d + \frac{2}{3} h_{fs} + \frac{2}{3} h_{fd}\right) \times L$$

But from equation (20.21), we know that work done by pump is proportional to the area of the indicator diagram.

$\therefore$ Work done by pump per second $\propto \left(h_s + h_d + \frac{2}{3} h_{fs} + \frac{2}{3} h_{fd}\right) \times L$

$$= KL \left(h_s + h_d + \frac{2}{3} h_{fs} + \frac{2}{3} h_{fd}\right)$$

where K = a constant of proportionality

$$= \frac{\rho g A N}{60} \qquad \text{...for a single-acting}$$

$$= \frac{2\rho gAN}{60} \quad \text{...for a double-acting}$$

$\therefore$ Work done by pump per second for a single-acting

$$= \frac{\rho gALN}{60}\left(h_s + h_d + \frac{2}{3}h_{fs} + \frac{2}{3}h_{fd}\right) \quad \text{...(20.22)}$$

and for a double-acting $$= \frac{2\rho gALN}{60}\left(h_s + h_d + \frac{2}{3}h_{fs} + \frac{2}{3}h_{fd}\right) \quad \text{...(20.23)}$$

Problem 20.10 *A single-acting reciprocating pump has a stroke length of 15 cm. The suction pipe is 7 metre long and the ratio of the suction diameter to the plunger diameter is 3/4. The water level in the sump is 2.5 metres below the axis of the pump cylinder, and the pipe connecting the sump and pump cylinder is 7.5 cm diameter. If the crank is running at 75 r.p.m., determine the pressure head on the piston :*

(i) in the beginning of the suction stroke, (ii) in the end of the suction stroke, and (iii) in the middle of the suction stroke.

Take co-efficient of friction as 0.01.

Solution. Given :

Stroke length, $L = 15 \text{ cm} = 0.15 \text{ m}$

$\therefore$ Crank radius, $r = \frac{L}{2} = \frac{0.15}{2} = 0.075 \text{ m}$

Length of suction pipe, $l_s = 7.0 \text{ m}$

$$\frac{\text{Suction pipe diameter}}{\text{Plunger diameter}} = \frac{d_s}{D} = \frac{3}{4}$$

$\therefore$ $$\frac{\text{Area of suction pipe}}{\text{Area of plunger}} = \frac{a_s}{A} = \left(\frac{3}{4}\right)^2 = \frac{9}{16}$$

Suction head, $h_s = 2.5$

Diameter of suction pipe, $d_s = 7.5 \text{ cm} = 0.075 \text{ m}$

Crank speed, $N = 75 \text{ r.p.m.}$

$\therefore$ Angular speed, $\omega = \frac{2\pi N}{60} = \frac{2 \times \pi \times 75}{60} = 2.5\ \pi \text{ rad/s.}$

Friction co-efficient, $f = 0.01$

The pressure head due to acceleration in suction pipe is given by equation (20.14), as

$$h_{as} = \frac{l_s}{g} \times \frac{A}{a_s} \times \omega^2 \times r \cos\theta$$

$$= \frac{7.0}{9.81} \times \frac{16}{9} \times (2.5\ \pi)^2 \times 0.075 \cos\theta \qquad \left(\because \frac{A}{a_s} = \frac{16}{9}\right)$$

$$= 5.87 \cos\theta$$

The loss of head due to friction in suction pipe is given by equation (20.18)as

$$h_{fs} = \frac{4fl_s}{d_s \times 2g} \times \left(\frac{A}{a_s}\omega r \sin\theta\right)^2$$

$$= \frac{4 \times 0.01 \times 7.0}{0.075 \times 2 \times 9.81} \times \left(\frac{16}{9} \times 2.5\pi \times 0.075 \times \sin \theta \right)^2 = 0.208 \sin^2 \theta.$$

(*i*) *Pressure head on the piston in the beginning of suction stroke :*

(Refer to Fig. 20.8). At the beginning of suction stroke, $\theta = 0^o$ and pressure head

$= (h_s + h_{as})$ m below atmospheric pressure head

$= 2.5 + 5.87 =$ **8.37 m vacuum. Ans.**

(*ii*) *Pressure head on the piston at the end of suction stroke :*

At the end of the suction stroke, $\theta = 180^o$ and hence cos θ

$= -1$ and sin $\theta = 0$

The pressure head $= (h_s - h_{as})$ m below atmospheric pressure head

$= H_{atm} - (h_s - h_{as})$ m abs. $= H_{atm} - (2.5 - 5.87)$ m abs.

$= H_{atm} - (-3.37)$ m abs. $= H_{atm} + 3.37$ m abs. = **3.37 m (gauge). Ans.**

(*iii*) *Pressure head on the piston in the middle of suction stroke :*

In the middle of suction stroke, $\theta = 90°$ and hence cos $\theta = 0$ and sin $\theta = 1$. The pressure head

$= (h_s + h_{fs})$ m below atmospheric pressure head

= (2.5 + 0.208) m vacuum = **2.708 m vacuum. Ans.**

Problem 20.11 *The diameter and stroke length of a single-acting reciprocating pump are 12 cm and 20 cm respectively. The lengths of suction and delivery pipes are 8 m and 25 m respectively and their diameters are 7.5 cm. If the pump is running at 40 r.p.m. and suction and delivery heads are 4 m and 14 m respectively, find the pressure head in the cylinder :*

(*i*) *at the beginning of the suction and delivery stroke,*

(*ii*) *in the middle of suction and delivery stroke, and*

(*iii*) *at the end of the suction and delivery stroke.*

Take atmospheric pressure head = 10.30 metres of water and f = .009 for both pipes.

Solution. Given :

Diameter of cylinder, $D = 12$ cm $= 0.12$ m

Stroke length, $L = 20$ cm $= 0.20$ m

$\therefore$ Crank radius, $r = \frac{L}{2} = \frac{.20}{2} = 0.10$ m

Length of suction pipe, $l_s = 8$ m

Length of delivery pipe, $l_d = 25$ m

Dia. of suction pipe, $d_s = 7.5$ cm $= 0.075$ m

Dia. of delivery pipe, $d_d = 7.5$ cm $= 0.075$ m

Speed of pump, $N = 40$ r.p.m.

Suction head, $h_s = 4$ m

Delivery head, $h_d = 14$ m

Atmospheric pressure head, $H_{atm} = 10.3$ m of water

Co-efficient of friction, $f = .009$.

We know that angular velocity, $\omega = \frac{2\pi N}{60} = \frac{2\pi \times 40}{60} = 4.188$ rad/s.

Using equation (20.14), the pressure head due to acceleration in suction pipe is obtained as

$$h_{as} = \frac{l_s}{g} \times \frac{A}{a_s} \times \omega^2 r \cos\theta = \frac{8}{9.81} \times \frac{\frac{\pi}{4}D^2}{\frac{\pi}{4}d_s^2} \times 4.188^2 \times 0.1 \times \cos\theta$$

$$= \frac{8}{9.81} \times \left(\frac{D}{d_s}\right)^2 \times 4.188^2 \times 0.1 \times \cos\theta$$

$$= \frac{8}{9.81} \times \left(\frac{.120}{.075}\right)^2 \times 4.188^2 \times 0.1 \times \cos\theta = 3.66 \times \cos\theta \text{ m.}$$

Similarly, the pressure head due to acceleration in delivery pipe is obtained from equation (20.15) as

$$h_{ad} = \frac{l_d}{g} \times \frac{A}{a_d} \times \omega^2 r \cos\theta$$

$$= \frac{25}{9.81} \times \frac{D^2}{d_d^2} \times 4.188^2 \times 0.1 \times \cos\theta$$

$$= \frac{25}{9.81} \times \left(\frac{.120}{.075}\right)^2 \times 4.188^2 \times 0.1 \times \cos\theta = 11.44 \times \cos\theta \text{ m.}$$

Using equation (20.18) for the loss of head due to friction in suction pipe,

$$h_{fs} = \frac{4fl_s}{d_s \times 2g} \times \left(\frac{A}{a_s}\omega r \sin\theta\right)^2$$

$$= \frac{4 \times .009 \times 8}{.075 \times 2 \times 9.81} \times \left(\frac{\frac{\pi}{4}D^2}{\frac{\pi}{4}d_s^2} \times 4.188 \times .1 \times \sin\theta\right)^2$$

$$= \frac{4 \times .009 \times 8}{.075 \times 2 \times 9.81} \times \left(\frac{.12^2}{.075^2} \times 4.188 \times .1\right)^2 \times \sin^2\theta = 0.225 \sin^2\theta.$$

Similarly, loss of head due to friction in delivery pipe is obtained from equation (20.19) as

$$h_{fd} = \frac{4 \times f \times l_d}{d_d \times 2g} \times \left[\frac{A}{a_d}\omega r \sin\theta\right]^2$$

$$= \frac{4 \times .009 \times 25}{0.075 \times 2 \times 9.81}\left[\frac{D^2}{d_d^2} \times 4.188 \times 0.1 \times \sin\theta\right]^2$$

$$= 0.6116\left[\frac{.12^2}{.075^2} \times 4.188 \times 0.1\right]^2 \times \sin^2\theta = 0.703 \sin^2\theta.$$

(*i*) **Pressure head in the cylinder at the beginning of suction and delivery strokes (Fig. 20.8).** At the beginning of suction and delivery strokes, $\theta = 0°$.

$\therefore$ $h_{as} = 3.66 \cos 0° = 3.66$ m

and $h_{ad} = 11.44 \cos 0° = 11.44$ m

Pressure head in the cylinder at the beginning of suction stroke

$= (h_s + h_{as})$ below atmospheric pressure head

$= H_{atm} - (h_s + h_{as})$ m (abs.)

$= 10.3 - (1 + 3.66) = 10.3 - 7.66 =$ **2.64 m (abs.) Ans.**

Pressure head in the cylinder at the beginning of delivery stroke

$= (h_d + h_{ad})$ above atmospheric pressure head

$= H_{atm} + (h_d + h_{ad})$ m (abs.)

$= 10.3 + (14 + 11.44) =$ **35.74 m (abs.) Ans.**

(*ii*) **Pressure head in the cylinder in the middle of suction and delivery strokes.** In the middle of suction and delivery strokes, $\theta = 90°$.

$\therefore$ $h_{as} = 0$, $h_{ad} = 0$, $h_{fs} = 0.225 \sin^2 90 = 0.225$ m and

$h_{fd} = 0.703 \sin^2 90 = 0.703$ m.

Pressure head in the cylinder at the beginning of suction stroke

$= (h_s + h_{fs})$ below the atmospheric pressure head

$= H_{atm} - (h_s + h_{fs})$ m (abs.)

$= 10.3 - (4 + 0.225) = 10.3 - 4.225 =$ **6.075 m (abs.) Ans.**

Pressure head in the cylinder at the beginning of delivery stroke

$= (h_d + h_{fd})$ above atmospheric pressure head

$= H_{atm} + (h_d + h_{fd})$ m (abs.)

$= 10.3 + (14 + 0.703) =$ **125.003 m (abs.) Ans.**

(*iii*) **Pressure head in the cylinder at the end of suction and delivery strokes.** At the end of suction and delivery strokes, $\theta = 180°$.

$\therefore$ $\cos \theta = -1$ and $\sin \theta = 0$

$\therefore$ $h_{as} = 3.66 \times (-1) = -3.66$ m

and $h_{ad} = 11.44 \times (-1) = -11.44$ m.

Pressure head in the cylinder at the end of suction stroke

$= (h_s - 3.66)$ below the atmospheric pressure head

$= H_{atm} - (h_s - 3.66)$ m (abs.) $= 10.3 - (4 - 3.66) =$ **9.96 m (abs.) Ans.**

Pressure head in the cylinder at the end of delivery stroke

$= (h_d - 11.44)$ above the atmospheric pressure head

$= H_{atm} + (h_d - 11.44)$ m (abs.)

$= 10.3 + (14 - 11.44) =$ **12.86 m (abs.) Ans.**

Problem 20.12 *For the single-acting reciprocating pump, given in Problem 20.11, find the power required to drive the pump, if water is flowing through the pump.*

Solution. Using equation (20.22) for the work done by the pump per second for a single-acting, we get

$$\text{Work done per sec} = \frac{\rho g A L N}{60}\left(h_s + h_d + \frac{2}{3}h_{fs} + \frac{2}{3}h_{fd}\right)$$

where $A = \frac{\pi}{4} D^2 = \frac{\pi}{4} \times .12^2 = 0.01131 \text{ m}^2$

L = Stroke length = 0.20 m, N = Speed = 40 r.p.m.

ρ = Density of water = 1000 kg/m^3, h_s = 4 m, h_d = 14 m

h_{fs} = Maximum loss of head due to friction in suction pipe = 0.225 m

h_{fd} = Maximum loss of head due to friction in delivery pipe = 0.703 m

$$\therefore \quad \text{Work done per second} = \frac{1000 \times 9.81 \times 0.01131 \times 0.20 \times 40}{60}\left(4 + 14 + \frac{2}{3} \times .225 + \frac{2}{3} \times .703\right)$$

$$= 14.793 \times (4 + 14 + 0.15 + 0.468) = 275.42 \text{ Nm/s}$$

$\therefore$ Power required to drive the pump in kW

$$= \frac{\text{Work done per second}}{1000} = \frac{275.42}{1000} = 0.2754 \text{ kW}.$$

20.8.5 Maximum Speed of a Reciprocating Pump. Maximum speed of a reciprocating pump is determined from the fact that the pressure in the cylinder during suction and delivery stroke, should not fall below the vapour pressure of the liquid, flowing through suction and delivery pipe. If the pressure in the cylinder is below the vapour pressure, the dissolved gases will be liberated from the liquid and cavitation * will take place. Also the continuous flow of liquid will not exist which means separation of liquid will take place. The pressure at which separation takes place is known as separation pressure and the head corresponding to separation pressure is called separation pressure head. It is denoted by h_{sep}. For water, the limiting value of separation pressure head (h_{sep}) is 7.8 below atmospheric pressure head or 10.3 – 7.8 = 2.5 m abs. The separation may take place during the suction stroke or during delivery stroke. The maximum speed of the reciprocating pump during suction and delivery strokes is calculated as :

(a) **Maximum Speed during Suction Stroke.** From the indicator diagram, drawn in Fig. 20.8, it is clear that the absolute pressure head during suction stroke is minimum at the beginning of the stroke. Thus, the separation can take place at the beginning of the stroke only. In that case, the abs. pressure head in the cylinder at the beginning of the stroke will be equal to separation pressure head (h_{sep}).

$$\therefore \quad h_{sep} = H_{atm} - (h_s + h_{as}) \text{ (abs.)}$$

or
$$h_{as} = H_{atm} - h_s - h_{sep} \qquad ...(i)$$

Generally, the values of h_{sep} and h_s (suction head) are given and hence 'h_{as}', the pressure head due to acceleration at the beginning of suction stroke can be obtained. The value of 'h_{as}' is also given by equation (20.14) as

$$h_{as} = \frac{l_s}{g} \times \frac{A}{a_s} \times \omega^2 r \qquad ...(ii)$$

Equating the two values of h_{as} given by equations (i) and (ii)

$$H_{atm} - h_s - h_{sep} = \frac{l_s}{g} \times \frac{A}{a_s} \times \omega^2 r \qquad ...(iii)$$

* Please refer to Art. 19.11 on page 980 for definition.

From equation (*iii*), the value of the ω (and hence speed *N*) can be obtained. This speed is the maximum speed of the reciprocating pump without separation during suction stroke.

(b) **Maximum Speed during Delivery Stroke.** During delivery stroke, the probability of separation is only at the end of the delivery stroke. The pressure head in the cylinder at the end of the delivery stroke from Fig. 20.8.

$$= (H_{atm} + h_d) - h_{ad} \text{ m (abs.)}$$

If separation is to be avoided, the above pressure head should be more than the separation pressure head (h_{sep}). In the limiting case

$$h_{sep} = (H_{atm} + h_d) - h_{ad} \text{ or } h_{ad} = (H_{atm} + h_d) - h_{sep}$$

But 'h_{ad}', the pressure head due to acceleration at the end of the delivery stroke is also given by

$$h_{ad} = \frac{l_d}{g} \times \frac{A}{a_d} \times \omega^2 \times r$$

Equating the two values of h_{ad}, we get

$$(H_{atm} + h_d) - h_{sep} = \frac{l_d}{g} \times \frac{A}{a_d} \omega^2 \times r \qquad ...(iv)$$

From the above equation (*iv*), the value of ω and hence speed *N*, can be calculated. This is the maximum speed of the reciprocating pump without separation during delivery stroke only.

The minimum of the two speeds given by above two cases (*a*) and (*b*) is the maximum speed of the reciprocating pump without separation during suction and delivery strokes.

Problem 20.13 *Find the maximum speed of a single-acting reciprocating pump to avoid separation, which occurs at 3.0 m of water (abs.) The pump has a cylinder of diameter 10 cm and a stroke length of 20 cm.The pump draws water from a sump and delivers to a tank. The water level in the sump is 3.5 m below the pump axis and in the tank the water level is 13 m above the pump axis. The diameter and length of the suction pipe are 4 cm and 5 m while of delivery pipe the diameter and length are 3 cm, 20 m respectively. Take atmospheric pressure head = 10.3 m of water.*

Solution. Given :

Separation pressure head, $h_{sep} = 3.0$ m of water (abs.)
Dia. of cylinder, $D = 10$ cm $= 0.10$ m
Stroke length, $L = 20$ cm $= 0.20$ m

$\therefore$ Crank radius, $r = \frac{L}{2} = \frac{0.20}{3} = 0.10$ m

Suction head, $h_s = 3.5$ m
Delivery head, $h_d = 13$ m
Dia. of suction pipe, $d_s = 4$ cm $= .04$ m
Length of suction pipe, $l_s = 5$ m
Dia. of delivery pipe, $d_d = 3$ cm $= .03$ m
Length of delivery pipe, $l_d = 20$ m
Atmos. pressure head, $H_{atm} = 10.3$ m.

(*a*) Maximum speed during suction stroke without separation is obtained from the relation, given by equation (*iii*),

$$H_{atm} - h_s - h_{sep} = \frac{l_s}{g} \times \frac{A}{a_s} \times \omega^2 r$$

or $$10.3 - 3.5 - 3.0 = \frac{5}{9.81} \times \frac{\frac{\pi}{4}D^2}{\frac{\pi}{4}d_s^2} \times \omega^2 \times 0.10 \qquad \left(\because\ A = \frac{\pi}{4}D^2,\ a_s = \frac{\pi}{4}d_s^2\right)$$

or $$3.8 = \frac{5}{9.81} \times \frac{.1 \times .1}{.04 \times .04} \times \omega^2 \times 0.1 = .3185\ \omega^2$$

$\therefore$ $$\omega = \sqrt{\frac{3.8}{.3185}} = 3.454 \text{ rad/s.}$$

But $$\omega = \frac{2\pi N}{60} \quad \therefore \quad \frac{2\pi N}{60} = 3.454$$

$\therefore$ $$N = \frac{60 \times 3.454}{2\pi} = 32.98 \text{ r.p.m.} \qquad ...(i)$$

(*b*) Maximum speed during delivery stroke without separation is obtained from equation (*iv*),

$$(H_{atm} + h_d) - h_{sep} = \frac{l_d}{g} \times \frac{A}{a_d} \times \omega^2 \times r$$

$$(10.3 + 13.0) - 3.0 = \frac{20}{9.81} \times \frac{D^2}{d_d^2} \times \omega^2 \times .1 = \frac{20}{9.81} \times \frac{0.1 \times .1}{.03 \times .03} \times \omega^2 \times .1$$

or $$20.3 = 2.265\ \omega^2$$

$\therefore$ $$\omega = \sqrt{\frac{20.3}{2.265}} = 2.994 \text{ rad/s.}$$

But $$\omega = \frac{2\pi N}{60} = 2.994$$

$\therefore$ $$N = \frac{60 \times 2.994}{2\pi} = 28.59 \text{ r.p.m.} \qquad ...(ii)$$

The minimum of the two speeds given by equations (*i*) and (*ii*) is the maximum speed of the pump, without separation.

$\therefore$ Maximum speed without separation = **28.59 r.p.m. Ans.**

▶ 20.9 AIR VESSELS

An air vessel is a closed chamber containing compressed air in the top portion and liquid (or water) at the bottom of the chamber. At the base of the chamber there is an opening through which the liquid (or water) may flow into the vessel or out from the vessel. When the liquid enters the air vessel, the air gets compressed further and when the liquid flows out the vessel, the air will expand in the chamber.

An air vessel is fitted to the suction pipe and to the delivery pipe at a point close to the cylinder of a single-acting reciprocating pump :

(*i*) to obtain a continuous supply of liquid at a uniform rate,

(*ii*) to save a considerable amount of work in overcoming the frictional resistance in the suction and delivery pipes, and

(*iii*) to run the pump at a high speed without separation.

Fig. 20.9 shows the single-acting reciprocating pump to which air vessels are fitted to the suction and delivery pipes. The air vessels act like an intermediate reservoir. During the first half of the suction stroke, the piston moves with acceleration, which means the velocity of water in the suction pipe is more than the mean velocity and hence the discharge of water entering the cylinder will be more than the mean discharge. This excess quantity of water will be supplied from the air vessel to the cylinder in such a way that the velocity in the suction pipe below the air vessel is equal to mean velocity of flow. During the second half of the suction stroke, the piston moves with retardation and hence velocity of flow in the suction pipe is less than the mean velocity of flow. Thus, the discharge entering the cylinder will be less than the mean discharge. The velocity of water in the suction pipe due to air vessel is equal to mean velocity of flow and discharge required in cylinder is less than the mean discharge. Thus, the excess water flowing in suction pipe will be stored into air vessel, which will be supplied during the first half of the next suction stroke.

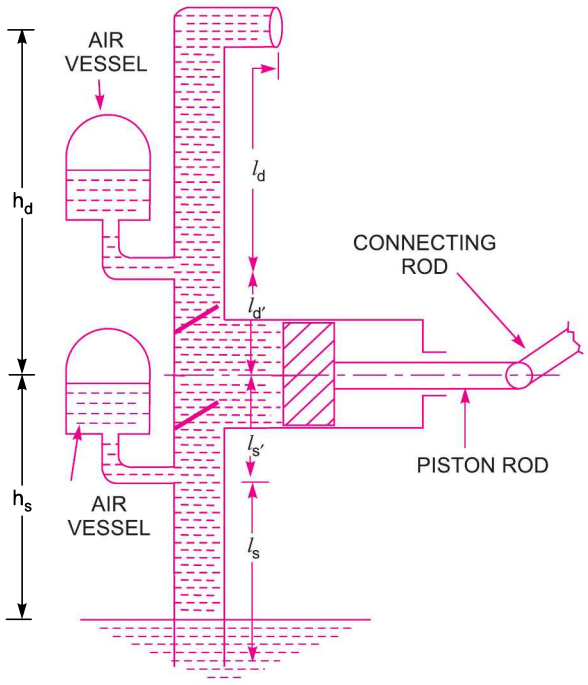

Fig. 20.9 *Air vessels fitted to reciprocating pump.*

When the air vessel is fitted to the delivery pipe, during the first half of delivery stroke, the piston moves with acceleration and forces the water into the delivery pipe with a velocity more than the mean velocity. The quantity of water in excess of the mean discharge will flow into the air vessel. This will compress the air inside the vessel. During the second half of the delivery stroke, the piston moves with retardation and the velocity of water in the delivery pipe will be less than the mean velocity. The water already stored into the air vessel will start flowing into the delivery pipe and the velocity of flow in the delivery pipe beyond the point to which air vessel is fitted will become equal to the mean velocity. Hence, the rate of flow of water in the delivery pipe will be uniform.

Let A = Cross-sectional area of the cylinder,

a = Cross-sectional area of suction or delivery pipe,

l_d = Length of delivery pipe beyond the air vessel,
l_d' = Length of delivery pipe between cylinder and air vessel,
l_s' = Length of suction pipe between cylinder and air vessel,
l_s = Length of suction pipe below air vessel,
h_{ad} = Pressure head due to acceleration in delivery pipe,
h_{as} = Pressure head due to acceleration in suction pipe,
h_{fd} = Loss of head due to friction in delivery pipe beyond the air vessel,
h_{fd}' = Loss of head due to friction in delivery pipe between cylinder and air vessel,
h_{fs} = Loss of head due to friction in suction pipe below the air vessel, and
h_{fs}' = Loss of head due to friction in suction pipe between cylinder and air vessel.

The effect of acceleration will be observed only in the lengths l_d' and l_s' which may be made very small by fitting air vessels very close to the cylinder. The velocity of flow of water in the length l_d and l_s will be equal to mean velocity of flow.

For a single-acting, discharge per second is given by equation (20.1), as

$$Q = \frac{ALN}{60}, \qquad \text{where } L = \text{Length of stroke}$$

$\therefore$ Mean velocity,
$$\bar{V} = \frac{\text{Discharge}}{\text{Area of pipe}} = \frac{Q}{a} = \frac{ALN}{60a}$$

$$= \frac{AL}{60a} \times \frac{60\omega}{2\pi} \qquad \left(\because \ \omega = \frac{2\pi N}{60} \text{ or } N = \frac{60\omega}{2\pi}\right)$$

$$= \frac{A}{a} \times L \times \frac{\omega}{2\pi} = \frac{A}{a} \times 2r \times \frac{\omega}{2\pi} \qquad (\because \ L = 2r)$$

$$= \frac{A}{a} \times \frac{\omega r}{\pi} \qquad ...(20.24)$$

The velocity of water in the suction or delivery pipes for the lengths l_s' and l_d' due to acceleration and retardation of the piston is given by equation (20.11) as

$$v = \frac{A}{a}\omega r \sin \omega t = \frac{A}{a}\omega r \sin \theta \qquad (\because \ \theta = \omega t)$$

(a) **Pressure head in the cylinder during delivery stroke.** The pressure head due to acceleration in the delivery pipe of length l_d' (between air vessel and cylinder) is given by equation (20.15) as

$$h_{ad} = \frac{l_d'}{g} \times \frac{A}{a_d}\omega^2 r \cos \theta \qquad ...(i)$$

Loss of head due to friction in the delivery pipe for lengths l_d' is given as

$$h_{fd}' = \frac{4f \times l_d' \times v^2}{d \times 2g}$$

where for delivery pipe, $v = \frac{A}{a_d}\omega r \sin \theta$

d = dia. of delivery pipe = d_d

$$\therefore \qquad h_{fd}' = \frac{4f \times l_d'}{d_d \times 2g} \times \left(\frac{A}{a_d}\omega r \sin\theta\right)^2 \qquad ...(ii)$$

Loss of head due to friction in the delivery pipe for the length beyond the air vessel (*i.e.,* length l_d),

$$h_{fd} = \frac{4f \times l_d \times \left(\overline{V}_d\right)^2}{d_d \times 2g}$$

where $\overline{V}_d$ = Mean velocity in delivery pipe = $\frac{A}{a_d} \times \frac{\omega r}{\pi}$ [from equation (20.24)]

$$\therefore \qquad h_{fd} = \frac{4f \times l_d}{d_d \times 2g} \times \left(\frac{A}{a_d} \times \frac{\omega r}{\pi}\right)^2 \qquad ...(iii)$$

The pressure head in the cylinder during delivery stroke is given as :

(*i*) At the beginning of the delivery stroke, $\theta = 0°$, $\sin\theta = 0$ and $\cos\theta = 1$ and hence total pressure head

$= (h_d + h_{ad} + h_{fd}' + h_{fd})$ + velocity head at the outlet of delivery

$$= h_d + h_{ad} + h_{fd}' + h_{fd} + \frac{\overline{V}_d^2}{2g} \qquad (\because \text{ Velocity at outlet is equal to mean velocity})$$

$$= h_d + \frac{l_d'}{g} \times \frac{A}{a_d}\omega^2 r + 0 + \frac{4f \times l_d}{d_d \times 2g} \times \left(\frac{A}{a_d} \times \frac{\omega r}{\pi}\right)^2 + \frac{\left(\frac{A}{a_d} \times \frac{\omega r}{\pi}\right)^2}{2g} \qquad \left(\because \overline{V_d} = \frac{A}{a_d} \times \frac{\omega r}{\pi}\right)$$

$$= h_d + \frac{l_d'}{g} \times \frac{A}{a_d}\omega^2 r + \frac{4fl_d}{d_d \times 2g} \times \left(\frac{A}{a_d} \times \frac{\omega r}{\pi}\right)^2 + \frac{1}{2g}\left(\frac{A}{a_d} \times \frac{\omega r}{\pi}\right)^2 \qquad ...(20.25)$$

(*ii*) In the middle of the stroke, $\theta = 90°$, $\sin\theta = 1$ and $\cos\theta = 0$ and hence total pressure head

$$= h_d + h_{ad} + h_{fd}' + h_{fd} + \frac{\overline{V}_d^2}{2g} \text{ above atmospheric pressure head}$$

$$= h_d + 0 + \frac{4f \times l_d'}{d_d \times 2g} \times \left(\frac{A}{a_d}\omega r\right)^2 + \frac{4f \times l_d}{d_d \times 2g} \times \left(\frac{A}{a_d} \times \frac{\omega r}{\pi}\right)^2 + \frac{1}{2g}\left(\frac{A}{a_d} \times \frac{\omega r}{\pi}\right)^2$$

$$= h_d + \frac{4f \times l_d'}{d_d \times 2g} \times \left(\frac{A}{a_d}\omega r\right)^2 + \frac{4f \times l_d}{d_d \times 2g} \times \left(\frac{A}{a_d} \times \frac{\omega r}{\pi}\right)^2 + \frac{1}{2g}\left(\frac{A}{a_d} \times \frac{\omega r}{\pi}\right)^2 \qquad ...(20.26)$$

(*iii*) At the end of the delivery stroke, $\theta = 180°$, $\sin\theta = 0$ and $\cos\theta = -1$ and hence total pressure head

$$= h_d - \frac{l_d'}{g} \times \frac{A}{a_d}\omega^2 r + \frac{4f \times l_d}{d_d \times 2g} \times \left(\frac{A}{a_d} \times \frac{\omega r}{\pi}\right)^2 + \frac{1}{2g}\left(\frac{A}{a_d} \times \frac{\omega r}{\pi}\right)^2 \qquad ...(20.27)$$

In equations (20.25), (20.26) and (20.27), the quantities

$$\left(\frac{l_d'}{g} \times \frac{A}{a_d}\omega^2 r\right) \text{ and } \left[\frac{4f \times l_d'}{d_a \times 2g} \times \left(\frac{A}{a_d}\omega r\right)^2\right]$$

are very small and can be neglected.

(*b*) **Pressure head in the cylinder during suction stroke.** The pressure head due to acceleration in the suction pipe of length l_s' (between air vessel and cylinder) is given as

$$h_{as}' = \frac{l_s'}{g} \times \frac{A}{a_s} \omega^2 r \cos\theta$$

Loss of friction head in the suction pipe of length l_s' given as

$$h_{fs}' = \frac{4f \times l_s' \times v_s^2}{d_s \times 2g}$$

where for suction pipe, the velocity (v_s) is given by equation (20.11) as $v_s = \frac{A}{a_s} \omega r \sin\theta$

Substituting the value of v_s in h_{fs}', we get

$$h_{fs}' = \frac{4 \times f \times l_s'}{d_s \times 2g} \times \left(\frac{A}{a_s} \omega r \sin\theta\right)^2$$

Loss of head due to friction in the suction pipe for the length below the air vessel (*i.e.,* lengths l_s),

$$h_{fs} = \frac{4f \times l_s}{d_s \times 2g} \times \left(\overline{V_s}\right)^2$$

where $\overline{V_s}$ is the mean velocity of flow and is given by equation (20.24) as $\overline{V_s} = \frac{A}{a_s} \times \frac{\omega r}{\pi}$

$$\therefore \qquad h_{fs} = \frac{4fl_s}{d_s \times 2g} \times \left(\frac{A}{a_s} \times \frac{\omega r}{\pi}\right)^2$$

Hence the pressure head in the cylinder during suction stroke is given as

(*i*) At the beginning of suction stroke $\theta = 0°$, $\sin\theta = 0$ and $\cos\theta = 1$ and hence pressure head

$$= \left(h_s + h_{as}' + h_{fs}' + h_{fs}\right)_{\theta = 0°} + \frac{\overline{V_s}^2}{2g} \text{ below atmospheric pressure head}$$

$$= h_s + \frac{l_s'}{g} \times \frac{A}{a_s} \omega^2 r + 0 + \frac{4fl_s}{d_s \times 2g} \times \left(\frac{A}{a_s} \times \frac{\omega r}{\pi}\right)^2 + \frac{1}{2g}\left(\frac{A}{a_s} \times \frac{\omega r}{\pi}\right)^2$$

$$= h_s + \frac{l_s'}{g} \times \frac{A}{a_s} \omega^2 r + \frac{4fl_s}{d_s \times 2g}\left(\frac{A}{a_s} \times \frac{\omega r}{\pi}\right)^2 + \frac{1}{2g}\left(\frac{A}{a_s} \times \frac{\omega r}{\pi}\right)^2 \qquad \text{...(20.28)}$$

below atmospheric pressure head.

(*ii*) In the middle of suction stroke, $\theta = 90°$, $\sin\theta = 1$ and $\cos\theta = 0$ and hence pressure head

$$= \left(h_s + h_{as}' + h_{fs}' + h_{fs}\right)_{\theta = 90°} + \frac{\overline{V_s}^2}{2g} \text{ below atmospheric pressure head}$$

$$= h_s + 0 + \frac{4f \times l_s'}{d_s \times 2g} \times \left(\frac{A}{a_s} \omega r\right)^2 + \frac{4fl_s}{d_s \times 2g} \times \left(\frac{A}{a_s} \times \frac{\omega r}{\pi}\right)^2 + \frac{1}{2g}\left(\frac{A}{a_s} \times \frac{\omega r}{\pi}\right)^2$$

$$= h_s + \frac{4fl_s'}{d_s \times 2g} \times \left(\frac{A}{a_s}\omega r\right)^2 + \frac{4fl_s}{d_s \times 2g} \times \left(\frac{A}{a_s} \times \frac{\omega r}{\pi}\right)^2 + \frac{1}{2g}\left(\frac{A}{a_s} \times \frac{\omega r}{\pi}\right)^2 \quad ...(20.29)$$

(*iii*) At the end of the suction stroke, $\theta = 180°$, $\sin\theta = 0$ and $\cos\theta = -1$.

Hence pressure head = $\left(h_s + h_{as}' + h_{fs}' + h_{fs}\right)_{\theta = 180°} + \frac{\overline{V_s}^2}{2g}$ below atmospheric pressure head

$$= h_s - \frac{l_s'}{g} \times \frac{A}{a_s}\omega^2 r + 0 + \frac{4fl_s}{d_s \times 2g} \times \left(\frac{A}{a_s} \times \frac{\omega r}{\pi}\right)^2 + \frac{1}{2}\left(\frac{A}{a_s} \times \frac{\omega r}{\pi}\right)^2 \quad ...(20.30)$$

In equations (20.28), (20.29) and (20.30), the quantities $\left(\frac{l_s'}{g} \times \frac{A}{a_s}\omega^2 r\right)$ and $\left[\frac{4f \times l_s'}{d_s \times 2g} \times \left(\frac{A}{a_s}\omega r\right)^2\right]$ are very small and may be neglected.

(*c*) **Work done by reciprocating pump with air vessels.** Work done by reciprocating pump fitted with air vessels to the suction and delivery pipe

$$= \text{Weight of water discharged per second} \times \left[h_s + h_d + h_{fs} + h_{fd} + \frac{\overline{V_s}^2}{2g} + \frac{\overline{V_d}^2}{2g} + \frac{2}{3}h_{fs}' + \frac{2}{3}h_{fd}'\right] \text{ N-m/s.}$$

where weight of water discharged per second for a single-acting pump, $W = \frac{wALN}{60} = \frac{\rho gALN}{60}$.

Also the values of h_{fs}', h_{fd}', $\frac{\overline{V_s}^2}{2g}$ and $\frac{\overline{V_d}^2}{2g}$ are very small and hence they can be neglected.

$\therefore$ Work done per sec $= \frac{\rho gALN}{60}\left[h_s + h_d + h_{fs} + h_{fd}\right]$ ...(20.31)

(*d*) **Work saved by fitting air vessel.** By fitting air vessel the head loss due to friction in suction and delivery pipe is reduced. This reduction in the head loss saves a certain amount of energy, which can be calculated by finding the work done against friction without air vessel and with air vessel. The difference of the two gives the saving in work done.

(*i*) **Work done against friction without air vessels.** Consider a single-acting reciprocating pump without any air vessels on the pipes. The velocity of flow through the pipes is given by equation (20.11) as

$$v = \frac{A}{a}\,\omega \times r \sin\theta$$

and loss of head due to friction is given by equation (20.17) as $h_f = \frac{4fl}{d \times 2g} \times \left[\frac{A}{a}\omega r \sin\theta\right]^2$.

The variation of h_f with θ is parabolic in nature and hence indicator diagram for the loss of head due to friction in pipes will be a parabola. The work done by pump against friction per stroke is equal to the area of the indicator diagram due to friction.

∴ Work done by pump per stroke against friction,

$$W_1 = \text{Area of the parabola} = \frac{2}{3} \times \text{Base} \times \text{Height}$$

$$= \frac{2}{3} \times L \times \left[\frac{4fl}{d \times 2g} \times \left(\frac{A}{a} \omega r \right)^2 \right] \qquad (\because \quad \text{Height} = h_f \text{ at } \theta = 90°)$$

$$= \frac{2}{3} \times L \times \frac{4fl}{d \times 2g} \times \left(\frac{A}{a} \omega r \right)^2. \qquad ...(20.32)$$

(*ii*) **Work done against friction with air vessels.** By fitting an air vessel to the pump, the velocity of flow through the pipes (except for lengths l_s' and l_d' which may be considered negligible) is uniform and equal to mean velocity of flow, which is given by equation (20.24) as

$$\overline{V} = \frac{A}{a} \times \frac{\omega r}{\pi}$$

∴ Loss of head due to friction with air vessel is given as

$$= \frac{4fl \times \overline{V}^2}{d \times 2g} = \frac{4fl}{d \times 2g} \times \left(\frac{A}{a} \times \frac{\omega r}{\pi} \right)^2$$

The head loss due to friction with air vessel is independent of θ and hence indicator diagram will be a rectangle.

∴ Work done by pump per stroke against friction,

$$W_2 = \text{Area of the rectangle}$$

$$= \text{Base} \times \text{Height} = L \times \frac{4fl}{d \times 2g} \times \left(\frac{A}{a} \times \frac{\omega r}{\pi} \right)^2$$

$$= \frac{1}{\pi^2} \times L \times \frac{4fl}{d \times 2g} \times \left(\frac{A}{a} \omega r \right)^2 \qquad ...(20.33)$$

The work given by equation (20.33) is less than the work given by equation (20.32). Hence, by fitting an air vessel work is saved.

(*iii*) **Work saved in a single-acting reciprocating pump.** Hence, saving in work done per stroke is obtained by subtracting equation (20.33) from equation (20.32).

∴ Work saved per stroke $= W_1 - W_2$

$$= \frac{2}{3} L \times \frac{4fl}{d \times 2g} \times \left(\frac{A}{a} \omega r \right)^2 - \frac{1}{\pi^2} L \times \frac{4fl}{d \times 2g} \times \left(\frac{A}{a} \omega r \right)^2$$

$$= L \times \frac{4fl}{d \times 2g} \times \left(\frac{A}{a} \omega r \right)^2 \left[\frac{2}{3} - \frac{1}{\pi^2} \right] \qquad ...(20.34)$$

The percentage of the work saved per stroke

$$= \left(\frac{W_1 - W_2}{W_1} \right) \times 100 = \frac{L \times \frac{4fl}{d \times 2g} \times \left(\frac{A}{a} \omega r \right)^2 \left[\frac{2}{3} - \frac{1}{\pi^2} \right]}{\frac{2}{3} L \times \frac{4fl}{d \times 2g} \times \left(\frac{A}{a} \omega r \right)^2} \times 100$$

$$= \frac{\left(\frac{2}{3}\right) - \left(\frac{1}{\pi^2}\right)}{\left(\frac{2}{3}\right)} \times 100 = 84.8\%.$$

(*iv*) **Work saved in a double-acting reciprocating pump.** The work lost in friction per stroke in case of double-acting reciprocating pump without air vessel is the same as given in case of single-acting reciprocating pump. Hence, it is given by equation (20.32) as

$$W_1 = \frac{2}{3} \times L \times \frac{4fl}{d \times 2g} \times \left(\frac{A}{a}\omega r\right)^2$$

When the air vessel is fitted to the pipe near the cylinder, the mean velocity of flow, $\overline{V}$ for double-acting is given by,

$$\overline{V} = \frac{\text{Discharge}}{\text{Area of pipe}} = \frac{Q}{a} = \frac{2ALN}{60a}$$

$$= \frac{2A \times 2r}{60a} \times \frac{60\omega}{2\pi} \qquad \left(\because \quad L = 2r \text{ and } N = \frac{60\omega}{2\pi}\right)$$

$$= \frac{2A}{a} \times \frac{\omega r}{\pi}$$

$\therefore$ Loss of head due to friction for double-acting

$$= \frac{4fl \times \overline{V^2}}{d \times 2g} = \frac{4fl}{d \times 2g} \times \left(\frac{2A}{a} \times \frac{\omega r}{\pi}\right)^2$$

$\therefore$ Work lost due to friction per stroke

$$W_2 = \text{Area of the rectangle}$$

$$= L \times \frac{4fl}{d \times 2g} \times \left(\frac{2A}{a} \times \frac{\omega r}{\pi}\right)^2$$

$$= \frac{4}{\pi^2} \times L \times \frac{4fl}{d \times 2g} \times \left(\frac{A}{a} \times \omega r\right)^2 \qquad \text{....(20.34A)}$$

$\therefore$ Saving in work done per stroke $= \dfrac{W_1 - W_2}{W_1}$

$$= \frac{\frac{2}{3} \times L \times \frac{4fl}{d \times 2g} \times \left(\frac{A}{a} \times \omega r\right)^2 - \frac{4}{\pi^2} \times L \times \frac{4fl}{d \times 2g} \times \left(\frac{A}{a}\omega r\right)^2}{\frac{2}{3} \times L \times \frac{4fl}{d \times 2g} \times \left(\frac{A}{a} \times \omega r\right)^2} = \frac{\left(\frac{2}{3}\right) - \left(\frac{4}{\pi^2}\right)}{\left(\frac{2}{3}\right)} = 0.392 = 39.2\%.$$

(*e*) **Discharge of liquid into and from the air vessel. 1.** Let the air vessel is fitted to both suction and delivery pipes of a *single-acting* reciprocating pump. Due to air vessel, the liquid in suction and delivery pipes beyond air vessel will be moving with a constant mean velocity. This mean velocity in the pipes is given by equation (20.24) as

$$\overline{V} = \frac{A}{a} \times \frac{\omega r}{\pi}$$

The mean discharge ($\overline{Q}$) in the pipes (suction or delivery) will be equal to,

$$\overline{Q} = \overline{V} \times \text{area of pipe}$$

$$= \left(\frac{A}{a} \times \frac{\omega r}{\pi}\right) \times a \qquad (\because \quad a = \text{area of pipe})$$

$$= \frac{A \times \omega \times r}{\pi} \qquad ...(20.35)$$

The velocity of piston in the cylinder at any instant is given by equation (20.10) as

$$V = \omega r \times \sin(\omega t) = \omega r \times \sin\theta \qquad (\because \quad \omega t = \theta)$$

Hence instantaneous discharge to or from the cylinder of the pump will be as

$$Q_i = \text{Velocity of piston} \times \text{Area of piston}$$

$$= (\omega r \sin\theta) \times A \qquad (\because \quad A = \text{Area of piston})$$

$$= A\omega r \sin\theta \qquad ...(20.36)$$

The difference of the two discharges given by equations (20.36) and (20.35) will be equal to the rate of flow of liquid into or from the air vessel.

$\therefore$ Rate of flow of liquid into the air vessel

$$= \left(A\omega r \sin\theta - \frac{A\omega r}{\pi}\right) = A\omega r\left(\sin\theta - \frac{1}{\pi}\right) \qquad ...(20.37)$$

(*i*) *For air vessel fitted to delivery pipe.* The liquid will be flowing into the air vessel if equation (20.37) is positive. But if equation (20.37) is negative, then liquid will flow from the air vessel. And if equation (20.37) is zero, then no flow is taking place from or to the air vessel.

(*ii*) *For air vessel fitted to suction pipe.* If equation (20.37) is positive, then liquid is flowing from the air vessel. If equation (20.37) is negative, then liquid is flowing into the air vessel.

For no flow of liquid into or from the air vessel, the equation (20.37) should be zero.

$$\therefore \qquad A\omega r\left(\sin\theta - \frac{1}{\pi}\right) = 0 \quad \text{or} \quad \sin\theta - \frac{1}{\pi} = 0$$

or $$\sin\theta = \frac{1}{\pi} = 0.3183$$

$\therefore$ $$\theta = 18° 34' \text{ or } 161° 26'$$

2. For double-acting pump. The discharge for double-acting is given by equation (20.5) as,

$$Q = \frac{2ALN}{60} \qquad \left(\omega = \frac{2\pi N}{60} \text{ or } N = \frac{60\,\omega}{2\pi}\right)$$

$$= \frac{2AL}{60} \times \frac{60\omega}{2\pi} = \frac{AL\omega}{\pi} = \frac{A \times 2r \times \omega}{\pi} \qquad (\because \quad L = 2r)$$

$$= \frac{2A\omega r}{\pi}$$

The above discharge is the mean discharge. Hence for double-acting mean discharge (Q) is given by

$$Q = \frac{2A\omega r}{\pi}$$

But the instantaneous discharge (Q_i) to or from the cylinder of the pump will be

$$Q_i = \text{Velocity of piston} \times \text{Area of piston}$$

$$= (\omega r \sin\theta) \times A = A\omega r \sin\theta$$

Hence, rate of flow of liquid into air vessel

$$= Q_i - Q = A\omega r \sin\theta - \frac{2A\omega r}{\pi} = A\omega r\left(\sin\theta - \frac{2}{\pi}\right) \quad ...(20.38)$$

(i) For air vessel fitted to delivery pipe. If equation (20.38) is positive, the liquid is flowing into the air vessel fitted to delivery pipe. If equation (20.38) is negative, then liquid is flowing from the air vessel. And if equation (20.38) is zero then no flow is taking place into or from the air vessel.

(ii) For air vessel fitted to suction pipe. If equation (20.38) is positive, the liquid is flowing from the air vessel fitted to suction pipe. If equation (20.38) is negative, the liquid is flowing into the air vessel.

For no flow of liquid into or from the air vessel, equation (20.38) should be zero.

$$\therefore \quad A\omega r\left(\sin\theta - \frac{2}{\pi}\right) = 0 \text{ or } \sin\theta = \frac{2}{\pi} = 0.6366$$

$$\therefore \quad \theta = 39^\circ\ 32' \text{ or } 140^\circ\ 28'.$$

Problem 20.14 *The cylinder of a single-acting reciprocating pump is 15 cm in diameter and 30 cm in stroke. The pump is running at 30 r.p.m. and discharge water to a height of 12 m. The diameter and length of the delivery pipe are 10 cm and 30 m respectively. If a large air vessel is fitted in the delivery pipe at a distance of 2 m from the centre of the pump, find the pressure head in the cylinder.*

(*i*) *At the beginning of the delivery stroke, and*

(*ii*) *In the middle of the delivery stroke. Take f = .01*

Solution. Given :

Diameter of cylinder, $D = 15 \text{ cm} = 0.15 \text{ m}$

$\therefore$ Area, $A = \frac{\pi}{4} \times .15^2 = 0.01767 \text{ m}^2$

Stroke length, $L = 30 \text{ cm} = 0.30 \text{ m}$

$\therefore$ Crank radius, $r = \frac{L}{2} = \frac{0.30}{2} = 0.15 \text{ m}$

Speed of pump, $N = 30$ r.p.m.

$\therefore$ Angular speed $\omega = \frac{2\pi N}{60} = \frac{2 \times \pi \times 30}{60} = \pi \text{ rad/s.}$

Delivery head, $h_d = 12 \text{ m}$

Diameter of delivery pipe, $d_d = 10 \text{ cm} = 0.10 \text{ m}$

$\therefore$ Area, $a_d = (\pi/4)\ (.1)^2 = .007854$

Length of delivery pipe, $l = 30 \text{ m}$

Length of air vessel from the centre of the cylinder,

$$l_d' = 2 \text{ m}$$

$\therefore$ Length of delivery pipe above the air vessel,

$$l_d = l - l_d' = 30 - 2 = 28 \text{ m}$$

Co-efficient of friction, $f = 0.01$.

(*i*) The pressure head in the cylinder at the beginning of the delivery stroke is given by equation (20.25) as

$$= h_d + \frac{l_d'}{g} \times \frac{A}{a_d}\omega^2 r + \frac{4fl_d}{d_d \times 2g} \times \left(\frac{A}{a_d} \times \frac{\omega r}{\pi}\right)^2 + \frac{1}{2g}\left(\frac{A}{a_d} \times \frac{\omega r}{\pi}\right)^2$$

$$= 12 + \frac{2}{9.81} \times \frac{.01767}{.007854} \times \pi^2 \times .15 + \frac{4 \times .01 \times 28}{0.1 \times 2 \times 9.81}\left(\frac{.01767}{.007854} \times \frac{\pi \times .15}{\pi}\right)^2$$

$$+ \frac{1}{2 \times 9.81}\left(\frac{.01767}{.007854} \times \frac{\pi \times .15}{\pi}\right)^2$$

$$= 12 + .6709 + 0.065 + .0058 = \mathbf{12.75\ m.\ Ans.}$$

(*ii*) The pressure head in the cylinder in the middle of the delivery stroke is given by equation (20.26) as

$$= h_d + \frac{4f \times l_d'}{d_d \times 2g} \times \left(\frac{A}{a_d}\omega r\right)^2 + \frac{4fl_d}{d_d \times 2g} \times \left(\frac{A}{a_d} \times \frac{\omega r}{\pi}\right)^2 + \frac{1}{2g}\left(\frac{A}{a_d}\frac{\omega r}{\pi}\right)^2$$

$$= 12 + \frac{4 \times .01 \times 2}{0.1 \times 2 \times 9.81} \times \left(\frac{.01767}{.007854} \times \pi \times .15\right)^2 + .065 + .0058$$

$$= 12 + .0458 + .065 + .0058 = \mathbf{12.116\ m.\ Ans.}$$

Problem 20.15 *A single-acting reciprocating pump is to raise a liquid of density 1200 kg per cubic metre through a vertical height of 11.5 metres, from 2.5 metres below pump axis to 9 metres above it. The plunger, which moves with S.H.M., has diameter 125 mm and stroke 225 mm. The suction and delivery pipes are 75 mm diameter and 3.5 metres and 13.5 metres long respectively. There is a large air vessel placed on the delivery pipe near the pump axis. But there is no air vessel on the suction pipe. If separation takes place at 8.829 N/cm^2 below atmospheric pressure, find :*

(*i*) *maximum speed, with which the pump can run without separation taking place, and*

(*ii*) *power required to drive the pump, if f = 0.02.*

Neglect slip for the pump.

Solution. Given :

Liquid density, $\rho = 1200$ kg/m^3

Total vertical height $= 11.5$ m

Suction head, $h_s = 2.5$ m

Delivery head, $h_d = 9$ m

Dia. of plunger, $D = 125$ mm $= 0.125$ m

Area of plunger, $A = \frac{\pi}{4} \times .125^2 = 0.0123$ m^2

Stroke length, $L = 225$ mm $= 0.225$ m

$\therefore$ Crank radius, $r = \frac{L}{2} = \frac{.225}{2} = .1125$

Dia. of suction and delivery pipe, $d = 75$ mm $= 0.075$ m

Area of suction and delivery pipe, $a = \frac{\pi}{4}(0.075)^2 = 0.00442$ m^2

Length of suction pipe, $l_s = 3.5$ m

Length of delivery pipe, $l_d = 13.5$ m.

Air vessel is placed on the delivery side only. Hence, the velocity in the delivery pipe will be uniform. And there will be no accelerating head on delivery side.

Separation pressure $= 8.829 \frac{\text{N}}{\text{cm}^2}$ below atmospheric pressure

$= 8.829 \times 10^4 \frac{\text{N}}{\text{m}^2}$ below atmospheric pressure

$\therefore$ Separation pressure head, $h_{sep} = \frac{\text{Separation pressure}}{\rho \times g}$

$= \frac{8.829 \times 10^4}{1200 \times 9.81}$ m below atmosphere

$= 7.5$ m below atmosphere ...(i)

(i) *Maximum speed, with which pump can run without separation taking place.*

Let N = Max. speed with which pump can run without separation taking place.

The separation can take place only at the beginning of suction stroke. As air vessel is not fitted on the suction pipe, there will be accelerating head acting on suction side.

Pressure head at the beginning of suction stroke

$= h_s + h_{as}$ below atmosphere

This pressure should be equal to h_{sep} in the limiting case

$\therefore \quad 7.5 = h_s + h_{as} = 2.5 + h_{as}$

$\therefore \quad h_{as} = 7.5 - 2.5 = 5.0$ m

But 'h_{as}' at the beginning of suction stroke

$$= \frac{l_s}{g} \times \frac{A}{a} \omega^2 r$$

$\therefore$
$$5.0 = \frac{3.5}{9.81} \times \frac{0.0123}{.00442} \times \omega^2 \times .1125$$

$\therefore$
$$\omega = \sqrt{\frac{5.0 \times 9.81 \times .00442}{3.5 \times .0123 \times .1125}} = 6.69 \text{ radians/s.}$$

But
$$\omega = \frac{2\pi N}{60}$$

$\therefore$
$$N = \frac{60 \times \omega}{2\pi} = \frac{60 \times 6.69}{2\pi} = \mathbf{63.88 \text{ r.p.m. Ans.}}$$

$\therefore$ Maximum speed with which the pump can run without separation taking place is 63.88 r.p.m.

(ii) *Power required to drive the pump.*

New discharge (Q) of the single-acting pump is given by equation (20.1) as

$$Q = \frac{ALN}{60} = \frac{0.0123 \times 0.225 \times 63.88}{60} = 0.00294 \text{ m}^3/\text{s}.$$

Velocity of liquid in delivery pipe will be uniform.

$\therefore$ Q = Area of delivery pipe × Velocity = $a \times v$

$\therefore$ $$v = \frac{Q}{a} = \frac{0.00294}{0.00442} = 0.665 \text{ m/s.}$$

$\therefore$ Head loss due to friction in delivery pipe,

$$h_{fd} = \frac{4f \times l_d \times v^2}{d \times 2g} = \frac{4 \times .02 \times 13.5 \times (.665)^2}{.075 \times 2 \times 9.81} = 0.324 \text{ m.}$$

During suction stroke, the value of maximum h_{fs} is given by

$$h_{fs} = \frac{4 \times f \times l_s}{d \times 2g} \times \left(\frac{A}{a}\omega r\right)^2 = \frac{4 \times .02 \times 3.5}{.075 \times 2 \times 9.81}\left(\frac{.0123}{.00442} \times 6.69 \times .1125\right)^2$$

$$= 0.834 \text{ m}$$

Now power required to drive the pump in kW

$$= \frac{\text{Work done/s}}{1000} = \frac{\rho \times g \times Q}{1000} \times \left[h_s + h_d + \frac{2}{3}h_{fs} + h_{fd}\right]$$

$$= \frac{1200 \times 9.81 \times .00294}{1000} \times \left[2.5 + 9.0 + \frac{2}{3} \times .834 + .324\right]$$

$$= \mathbf{0.428 \text{ kW. Ans.}}$$

Problem 20.16 *A double-acting reciprocating piston pump is pumping water (diameter of the piston 250 mm, diameter of piston rod, which is on one side of the piston 50 mm, piston stroke 380 mm). The suction and discharge heads are 4.5 m and 18.6 m respectively. Find the work done by the piston during outward stroke. Would the work done change for the inward stroke?*

Solution. Given :

Dia. of piston, $D = 250 \text{ mm} = 0.25 \text{ m}$

$\therefore$ Area of piston, $A = \frac{\pi}{4} \times D^2 = \frac{\pi}{4} \times 0.25^2 \text{ m}^2 = 0.0491 \text{ m}^2$

Dia. of piston rod, $d = 50 \text{ mm} = 0.05 \text{ m}$

$\therefore$ Area of piston rod, $a = \frac{\pi}{4} \times d^2 = \frac{\pi}{4} \times 0.05^2 = 0.001963 \text{ m}^2$

Stroke length, $L = 380 \text{ mm} = 0.380 \text{ m}$

Suction head, $h_s = 4.5 \text{ m}$

Discharge or delivery head, $h_d = 18.6 \text{ m}$

Find work done during outward stroke

In a double-acting pump for outward stroke, suction side will be towards the piston and delivery side will be towards the piston rod.

Hence, total work done during outward stroke

= Weight of water lifted × height through which water is lifted

+ Weight of water delivered × height through which water is delivered

$= \rho \times g \times Q_1 \times h_s + \rho \times g \times Q_2 \times h_d$

where during outward stroke, $Q_1 = A \times L = 0.0491 \times 0.380 = 0.01865\ m^3$

$Q_2 = (A - a) \times L$

$= (0.0491 - 0.001963) \times 0.380 = 0.01791\ m^3$

and $\rho \times g = 1000 \times 9.81\ N/m^3$

$\therefore$ Total work done during outward stroke

$= (1000 \times 9.81 \times 0.01865 \times 4.5 + 1000 \times 9.81 \times 0.01791 \times 18.6)\ Nm$

$= 9.81 \times 0.01865 \times 4.5 + 9.81 \times 0.01791 \times 18.6\ (kJ)$

$= (0.8233 + 3.268)\ kJ$ ($\because$ J = Nm)

$=$ **4.0913 kJ. Ans.**

For inward stroke, suction side will be towards the piston rod whereas the delivery side will be towards the piston.

$\therefore$ Total work done during inward stroke

$= \rho \times g \times Q_2 \times h_s + \rho \times g \times Q_1 \times h_d = \rho \times g\ (Q_2 \times h_s + Q_1 \times h_d)$

$= 1000 \times 9.81\ (0.01791 \times 4.5 + 0.01865 \times 18.6)\ Nm$

$= 1000 \times 9.81\ (0.0806 + 0.3468)\ J$

$= 9.81\ (0.0806 + 0.3468)\ kJ = 4.192\ kJ$

Hence, work done during inward stroke will be different. **Ans.**

Problem 20.17 *A single-acting reciprocating pump has a plunger diameter of 250 mm and stroke of 450 mm and it is driven with S.H.M. at 60 r.p.m. The length and diameter of delivery pipe are 60 m and 100 mm respectively. Determine the power saved in overcoming friction in the delivery pipe by fitting an air vessel on the delivery side of the pump. Assume friction factor = 0.01.*

Solution. Given :

Dia. of plunger, $D = 250\ mm = 0.25\ m$

$\therefore$ Area, $A = \frac{\pi}{4} \times 0.25^2$

Stroke length, $L = 450\ mm = 0.45\ m$

$\therefore$ Crank radius, $r = \frac{L}{2} = \frac{0.45}{2} = 0.225\ m$

Speed, $N = 60$ r.p.m.

$\therefore$ Angular speed, $\omega = 2\pi N/60 = 2\pi \times 60/60 = 2\pi$ rad/s.

Length of delivery pipe, $L = 60\ m$

Dia. of delivery pipe, $d = 100\ mm = 0.1\ m$

$\therefore$ Area of pipe, $a = \frac{\pi}{4} \times 0.1^2$

Friction factor, $f = 0.01$

Power saved is given by,

Power saved $= \rho \times g \times Q \times \left[\frac{2}{3}(h_f)_{\text{without air vessel}} - (h_f)_{\text{with air vessel}}\right]$

where $\rho \times g = 1000 \times 9.81 \frac{\text{N}}{\text{m}^3}$

$$Q = \frac{ALN}{60} = \frac{\pi}{4} \times \frac{0.25^2 \times 0.45 \times 60}{60} = 0.02209 \text{ m}^3/\text{s}$$

Without air vessel, $$h_f = \frac{f^* \times L \times v^2}{d \times 2g} = \frac{f \times L}{d \times 2g} \times \left(\frac{A}{a} \omega \times r\right)^2 \qquad \left[\because \; v = \frac{A}{a} \times \omega \times r\right]$$

$$= \frac{0.01 \times 60}{0.1 \times 2 \times 9.81} \times \frac{\left(\frac{\pi}{4} \times 0.25^2 \times 2\pi \times 0.225\right)^2}{\frac{\pi}{4} \times 0.1^2} = 23.87 \text{ m}$$

With air vessel, $$h_f = \frac{f^* \times L \times \overline{V}^2}{d \times 2g}$$

$$= \frac{f^* \times L}{d \times 2g} \times \left(\frac{A}{a} \times \frac{\omega r}{\pi}\right)^2, \text{ where } \overline{V}^2 = \frac{A}{a} \times \frac{\omega \times r}{\pi}$$

$$= \frac{0.01 \times 60}{0.1 \times 2 \times 9.81} \times \left(\frac{\frac{\pi}{4} \times 0.25^2}{\frac{\pi}{4} \times 0.1^2} \times \frac{2\pi \times 0.225}{\pi}\right)^2 = 2.419 \text{ m.}$$

$\therefore$ Power saved $$= \rho \times g \times Q \times \left[\frac{2}{3}(h_f)_{\text{without air vessel}} - (h_f)_{\text{with air vessel}}\right]$$

$$= 1000 \times 9.81 \times 0.02209 \left[\frac{2}{3} \times 23.87 - 2.419\right] \text{ W}$$

$$= 9.81 \times 0.02209 \left[\frac{2}{3} \times 23.87 - 2.419\right] \text{ kW} = \mathbf{2.924 \text{ kW. Ans.}}$$

Problem 20.18 *A double-acting reciprocating pump runs at 120 r.p.m. When its suction pipe of 100 mm diameter is fitted with an air vessel on its suction side. The diameter of cylinder and stroke are 150 mm and 450 mm respectively. If piston is to be driven with S.H.M., find the rate of flow from or into the air vessel when the crank makes angles of 30° , 90° and 120° with the inner dead centre. Find also the crank angles at which there is no flow into or from the air vessel.*

Solution. Given :

Speed, $N = 120$ r.p.m.

$\therefore$ Angular speed, $$\omega = \frac{2\pi N}{60} = \frac{2\pi \times 120}{60} = 4\pi \text{ rad/s}$$

* Here friction factor is given and hence the formula is $h_f = \frac{f \times L \times V^2}{d \times 2g}$ and not $\frac{4f \times L \times V^2}{d \times 2g}$.

Dia. of suction pipe = 100 mm = 0.1 m

$\therefore$ Area of suction pipe, $a = \frac{\pi}{4}(0.1)^2 = 0.007854 \text{ m}^2$

Dia. of cylinder = 150 mm = 0.15 m

$\therefore$ Area of cylinder, $A = \frac{\pi}{4}(0.15)^2 = 0.01767 \text{ m}^2$

Stroke length, $L = 450 \text{ mm} = 0.45 \text{ m}$

$\therefore$ Crank radius, $r = \frac{L}{2} = \frac{0.45}{2} = 0.225 \text{ m}$

Find rate of flow from or into air vessel when $\theta = 30°$, $90°$ and $120°$

The rate of flow of liquid for double-acting pump into the air vessel is given by equation (20.38).

$\therefore$ Rate of flow of liquid into air vessel

$$= A\omega r\left(\sin\theta - \frac{2}{\pi}\right) = 0.01767 \times 4\pi \times 0.225\left(\sin\theta - \frac{2}{\pi}\right) = 0.04996\left(\sin\theta - \frac{2}{\pi}\right)$$

In this problem, air vessel is fitted to the suction pipe. Hence if the above rate of flow is positive, the liquid will be flowing from the air vessel. And if the above rate of flow is negative, the liquid will be flowing into the air vessel.

(*i*) *For* $\theta = 30°$.

The above rate of flow $= 0.04996\left(\sin 30° - \frac{2}{\pi}\right) = 0.04996(0.5 - 0.6366) =$ **-0.00682 m^3/s. Ans.**

Since the rate of flow is negative, hence the flow is taking place into the air vessel.

(*ii*) *For* $\theta = 90°$.

The rate of flow becomes $= 0.04996\left(\sin 90° - \frac{2}{\pi}\right) = 0.04996(1 - 0.6366) =$ **0.0181 m^3/s. Ans.**

As it is positive, hence rate of flow is taking place from the air vessel.

(*iii*) *For* $\theta = 120°$.

The rate of flow becomes $= 0.04996\left(\sin 120° - \frac{2}{\pi}\right) = 0.04996(0.866 - 0.6366) =$ **0.01146 m^3/s. Ans.**

As it is positive, hence rate of flow is taking place from the air vessel.

(*iv*) *Crank angle at which there is no flow into or from air vessel*

Let θ = angle at which there is no flow. But rate of flow

$$= 0.04996\left(\sin\theta - \frac{2}{\pi}\right)$$

For no flow from or into air vessel

$$0.04996\left(\sin\theta - \frac{2}{\pi}\right) = 0 \text{ or } \sin\theta = \frac{2}{\pi} = 0.6366$$

$\therefore$ $\theta = \sin^{-1} 0.6366 =$ **39° 32′** and **140° 28′. Ans.**

▶ 20.10 COMPARISON BETWEEN CENTRIFUGAL PUMPS AND RECIPROCATING PUMPS

Centrifugal pumps	*Reciprocating pumps*
1. The discharge is continuous and smooth.	1. The discharge is fluctuating and pulsating.
2. It can handle large quantity of liquid.	2. It handles small quantity of liquid only.
3. It can be used for lifting highly viscous liquids.	3. It is used only for lifting pure water or less viscous liquids.
4. It is used for large discharge through smaller heads.	4. It is meant for small discharge and high heads.
5. Cost of centrifugal pump is less as compared to reciprocating pump.	5. Cost of reciprocating pump is approximately four times the cost of centrifugal pump.
6. Centrifugal pump runs at high speed. They can be coupled to electric motor.	6. Reciprocating pump runs at low speed. Speed is limited due to consideration of separation and cavitation.
7. The operation of centrifugal pump is smooth and without much noise. The maintenance cost is low.	7. The operation of reciprocating pump is complicated and with much noise. The maintenance cost is high.
8. Centrifugal pump needs smaller floor area and installation cost is low.	8. Reciprocating pump requires large floor area and installation cost is high.
9. Efficiency is high.	9. Efficiency is low.

HIGHLIGHTS

1. A reciprocating pump consists of a cylinder with a piston, a suction pipe, a delivery pipe, a suction valve and a delivery valve.

2. Discharge through a pump per second is given as

$$Q = \frac{ALN}{60} \quad \text{...For a single-acting}$$

$$= \frac{2ALN}{60} \quad \text{...For a double-acting.}$$

3. Work done by reciprocating pump per second

$$= \frac{\rho g ALN}{60}(h_s + h_d) \quad \text{...For a single-acting}$$

$$= \frac{2\rho g ALN}{60}(h_s + h_d) \quad \text{...For a double-acting.}$$

4. Slip of a pump is defined as the difference between the theoretical discharge and actual discharge of the pump.

5. The pressure head (h_a) due to acceleration in the suction and delivery pipes is given as

$$h_{as} = \frac{l_s}{g} \times \frac{A}{a_s}\omega^2 r \cos\theta \quad \text{...For suction pipe}$$

$$h_{ad} = \frac{l_d}{g} \times \frac{A}{a_d}\omega^2 r \cos\theta \quad \text{... For delivery pipe.}$$

6. The loss of head due to friction in suction and delivery pipes is obtained from

$$h_f = \frac{4fl}{d \times 2g} \times \left(\frac{A}{a}\omega r \sin\theta\right)^2.$$

7. Indicator diagram is a graph between the pressure head in the cylinder and the distance travelled by the piston from inner dead centre for one complete revolution of the crank.
8. Work done by the pump is proportional to the area of the indicator diagram. Area of ideal indicator diagram is the same as the area of indicator diagram due to acceleration in suction and delivery pipes.
9. Work done by the pump per second due to acceleration and friction in suction and delivery pipes

$$= \frac{\rho g A L N}{60}\left(h_s + h_d + \frac{2}{3}h_{fs} + \frac{2}{3}h_{fd}\right) \quad \text{...For a single-acting}$$

$$= \frac{2\rho g A L N}{60}\left(h_s + h_d + \frac{2}{3}h_{fs} + \frac{2}{3}h_{fd}\right) \quad \text{...For a double-acting.}$$

10. Air vessel is used to obtain a continuous supply of water at uniform rate, to save a considerable amount of work and to run the pump at a high speed without separation.
11. Mean velocity ($\overline{V}$) for a single-acting pump is given as

$$\overline{V} = \frac{A}{a}\frac{\omega r}{\pi}.$$

12. Work done by reciprocating with air vessels fitted to suction and delivery pipes

$$\simeq \frac{\rho g A L N}{60}\left[h_s + h_d + h_{fs} + h_{fd}\right].$$

13. Work saved by fitting air vessels in a single-acting reciprocating pump is 84.8% while in a double-acting reciprocating pump, the work saved is 39.2%.

EXERCISE

(A) THEORETICAL PROBLEMS

1. What is a reciprocating pump ? Describe the principle and working of a reciprocating pump with a neat sketch. Why is a reciprocating pump not coupled directly to the motor ? Discuss the reason in detail.
2. Differentiate : (*i*) Between a single-acting and double-acting reciprocating pump, (*ii*) Between a single cylinder and double cylinder reciprocating pump.
3. Define slip, percentage slip and negative slip of a reciprocating pump.
4. How will you classify the reciprocating pumps ?
5. What is the effect of acceleration of the piston on the velocity and acceleration of the water in suction and delivery pipes? Obtain an expression for the pressure head due to acceleration in the suction and delivery pipes.
6. Find an expression for the head lost due to friction in suction and delivery pipes.
7. Define indicator diagram. How will you prove that area of indicator diagram is proportional to the work done by the reciprocating pump?
8. What is the effect of acceleration in suction and delivery pipes on indicator diagram ? Does the area of the indicator diagram change as compared to the area of ideal indicator diagram ?
9. Draw an indicator diagram, considering the effect of acceleration and friction in suction and delivery pipes. Find an expression for the work done per second in case of single-acting reciprocating pump.
10. What is an air vessel ? Describe the function of the air vessel for reciprocating pumps.

11. Show from first principle that the work saved, against friction in the delivery pipe of a single-acting reciprocating pump, by fitting an air vessel is 84.8% while for a double-acting reciprocating pump the work saved is only 39.20%.
12. What is negative slip in a reciprocating pump ? Explain with neat sketches the function of air vessels in a reciprocating pump.
13. Differentiate, with examples between :
    (*i*) Turbines and pumps, (*ii*) Impulse and reaction turbines,
    (*iii*) Radial and axial flow turbines, flow turbines, (*iv*) Inward and outward radial, and
    (*v*) Kaplan and propeller turbines.
14. Explain in brief how and when separation of flow takes place in a reciprocating pump. Discuss the preventive measures usually adopted for effective reduction of separation in such a pump.
15. Why is it that the speed of a reciprocating pump without air vessels is not high ? Explain with sketches.
16. Derive an expression for the head lost due to friction in the delivery pipe of a reciprocating pump with and without an air vessel.

(B) NUMERICAL PROBLEMS

1. A single-acting reciprocating pump running at 30 r.p.m., delivers 0.012 m^3/s of water. The diameter of the piston is 25 cm and stroke length is 50 cm. Determine : (*i*) The theoretical discharge of the pump, (*ii*) Co-efficient of discharge, and (*iii*) Slip and percentage slip of the pump.
   [**Ans.** (*i*) 0.01227 m^3/s, (*ii*) 0.978, (*iii*) .00027 m^2/s and 2.20%]
2. A double-acting reciprocating pump, running at 50 r.p.m. is discharging 900 litres of water per minute. The pump has stroke of 400 mm. The diameter of piston is 250 mm. The delivery and suction heads are 25 m and 4 m respectively. Find the slip of the pump and power required to drive the pump.
   [**Ans.** .0027 m^3/s, 9.3 kW]
3. A single-acting reciprocating pump has a cylinder of a diameter 150 mm and of stroke length 300 mm. The centre of the pump is 4 m above the water surface in the sump. The atmospheric pressure head is 10.3 m of water and pump is running at 40 r.p.m. If the length and diameter of the suction pipe are 5 m and 10 cm respectively, determine the pressure head due to acceleration in the cylinder : (*i*) At the beginning of the suction stroke, and (*ii*) In the middle of suction stroke. [**Ans.** (*i*) 3.018 m, (*ii*) 0]
4. If in Problem 3, the length and diameter of delivery pipe are 35 m and 100 mm respectively and water is delivered by the pump to a tank which is 25 m above the centre of the pump, determine the pressure head in the cylinder : (*i*) At the beginning of the delivery stroke, (*ii*) In the middle of the stroke, and (*iii*) At the end of the delivery stroke. [**Ans.** (*i*) 5.426 m (abs.), (*ii*) 35.3 m (abs.), (*iii*) 14.174 m (abs.)]
5. A single-acting reciprocating pump has piston diameter 15 cm and stroke length 30 cm. The centre of the pump is 5 m above the water level in the sump. The diameter and length of the suction pipe are 10 cm and 8 m respectively. The separation occurs if the absolute pressure head in the cylinder during suction stroke falls below 2.5 m of water. Calculate the maximum speed at which the pump can run without separation. Take atmospheric pressure head = 10.3 m of water. [**Ans.** 30.45 r.p.m.]
6. A single-acting reciprocating pump has a plunger of 100 mm diameter and a stroke length 200 mm. The centre of the pump is 3 m above the water level in the sump and 20 m below the water level in a tank to which water is delivered by the pump. The diameter and length of suction pipe are 50 mm and 5 m while of the delivery pipe are 40 mm and 30 m respectively. Determine the maximum speed at which the pump may be run without separation, if separation occurs at 7.3575 N/cm^2 below the atmospheric pressure. Take atmospheric pressure head = 10.3 m of water. [**Ans.** 36.22 r.p.m.]
7. The diameter and stroke length of a single-acting reciprocating pump are 100 mm and 200 mm respectively. The lengths of suction and delivery pipes are 10 m and 30 m respectively and their diameters are 50 mm. If the pump is running at 30 r.p.m. and suction and delivery heads are 3.5 m and 20 m respectively,

find the pressure head in the cylinder : (*i*) at the beginning of the suction and delivery stroke, (*ii*) in the middle of suction and delivery stroke, and (*iii*) at the end of the suction and delivery stroke. Take atmospheric pressure head = 10.3 m of water and co-efficient of friction = .009 for both pipes.

[**Ans.** (*i*) 2.776 m (abs.), 42.373 m (abs.), (*ii*) 6.22 m, 43.34 m, (*iii*) Not possible, 18.225 m]

8. For Problem 7, find the power required to drive the pump, if the liquid flowing through the pump is water.

[**Ans.** 0.25 kW]

9. The cylinder of a single-acting reciprocating pump is 125 mm in diameter and 250 mm in stroke. The pump is running at 40 r.p.m. and discharge water to a height of 15 m. The diameter and length of the delivery pipe are 100 mm and 30 m respectively. If a large air vessel is fitted in the delivery pipe at a distance of 1.5 m from the centre of the pump, find the pressure head in the cylinder : (*i*) At the beginning of the delivery stroke, and (*ii*) In the middle of the delivery stroke. Take the efficiency of friction = .01.

[**Ans.** (*i*) 15.566 m, (*ii*) 15.07 m]

21 CHAPTER

FLUID SYSTEM

▶ 21.1 INTRODUCTION

Fluid system is defined as the device in which power is transmitted with the help of a fluid which may be liquid (water or oil) or a gas (air) under pressure. Most of these devices are based on the principles of fluid statics and fluid kinematics. In this chapter, the following devices will be discussed:

1. The hydraulic press,
2. The hydraulic accumulator,
3. The hydraulic intensifier,
4. The hydraulic ram,
5. The hydraulic lift,
6. The hydraulic crane,
7. The fluid or hydraulic coupling,
8. The fluid or hydraulic torque converter,
9. The air lift pump, and
10. The gear-wheel pump.

▶ 21.2 THE HYDRAULIC PRESS

The hydraulic press is a device used for lifting heavy weights by the application of a much smaller force. It is based on Pascal's law, which states that the intensity of pressure in a static fluid is transmitted equally in all directions.

The hydraulic press consists of two cylinders of different diameters. One of the cylinder is of large diameter and contains a ram, while the other cylinder is of smaller diameter and contains a plunger as shown in Fig. 21.1. The two cylinders are connected by a pipe. The cylinders and pipe contain a liquid through which pressure is transmitted.

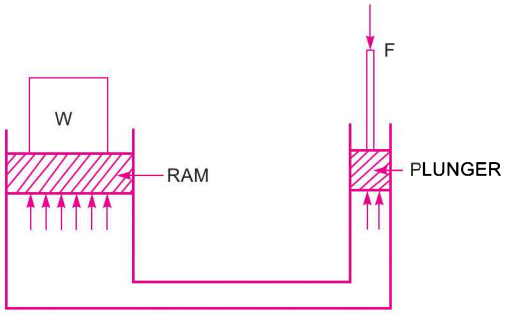

Fig. 21.1 *The hydraulic press.*

When a small force F is applied on the plunger in the downward direction, a pressure is produced on the liquid in contact with the plunger. This pressure is transmitted equally in all directions and acts on the ram in the upward direction as shown in Fig. 21.1. The heavier weight placed on the ram is then lifted up.

Let W = Weight to be lifted,
F = Force applied on the plunger,

A = Area of ram,
a = Area of plunger, and
p = Pressure intensity produced by force F.

$$= \frac{\text{Force } F}{\text{Area of plunger}} = \frac{F}{a}$$

Due to Pascal's law, the above intensity of pressure will be equally transmitted in all directions. Hence, the pressure intensity at the ram will be = $p = \frac{F}{a}$.

But the pressure intensity on ram is also = $\frac{\text{Weight}}{\text{Area of ram}} = \frac{W}{A}$.

Equating the pressure intensity on ram, $\frac{F}{a} = \frac{W}{A}$

$$\therefore \qquad W = \frac{F}{a} \times A. \qquad \text{...(21.1)}$$

21.2.1 Mechanical Advantage. The ratio of weight lifted to the force applied on the plunger is defined as the mechanical advantage. Mathematically, mechanical advantage is written as

$$\text{M. A.} = \frac{W}{F}. \qquad \text{...(21.2)}$$

21.2.2 Leverage of the Hydraulic Press. If a lever is used for applying force on the plunger, then a force F' smaller than F can lift the weight W as shown in Fig. 21.2. The ratio of L/l is called the leverage of the hydraulic press.

Taking moments about Q, $F' \times L = F \times l$

$$\therefore \qquad F = F' \times \frac{L}{l} \qquad \text{...(21.3)}$$

Substituting the value of F in equation (21.1), we get the expression for weight lifted as

$$W = \left(F' \times \frac{L}{l}\right) \times \frac{A}{a} = F' \times \frac{L}{l} \times \frac{A}{a} \qquad \text{...(21.4)}$$

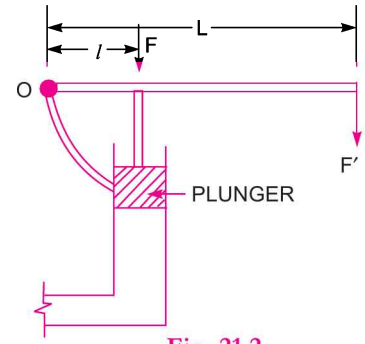

Fig. 21.2

21.2.3 Actual Heavy Hydraulic Press. Based on the nature of the work required, actual hydraulic press is different in shape. But all actual hydraulic press consist of a ram sliding in a cylinder to which high-pressure liquid is forced.

Fig. 21.3 shows one of the actual hydraulic press. It consists of a fixed cylinder in which a ram is sliding. To the lower end of the ram, movable plate is attached. As the ram moves up and down, the movable plate attached to the ram also moves up and down between two fixed plates. When any liquid under high pressure is supplied into the cylinder, the ram

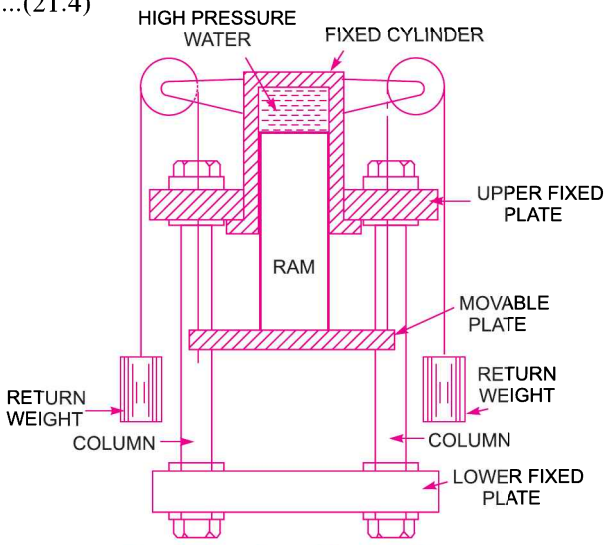

Fig. 21.3 *Actual hydraulic press.*

moves in the downward direction and exerts a force equal to the product of intensity of pressure supplied and area of the ram, on any material placed between the lower fixed plate and the movable plate. Thus the material gets pressed.

To bring back the ram in the upward position, the liquid from the cylinder is taken out. Then by the action of the return weights, the ram along with the movable plate will move up.

Problem 21.1 *A hydraulic press has a ram of 300 mm diameter and a plunger of 45 mm diameter. Find the weight lifted by the hydraulic press when the force applied at the plunger is 50 N.*

Solution. Given :

Diameter of ram, $D = 300 \text{ mm} = 0.30 \text{ m}$

Diameter of plunger, $d = 45 \text{ mm} = 0.045 \text{ m}$

Force on plunger, $F = 50 \text{ N}$

Let weight lifted $= W \text{ N}$

Area of ram, $A = \frac{\pi}{4} D^2 = \frac{\pi}{4} (0.30)^2 = 0.07068 \text{ m}^2$

Area of plunger, $a = \frac{\pi}{4} d^2 = \frac{\pi}{4} (.045)^2 = .00159 \text{ m}^2$

The weight lifted (W) is given by equation (21.1) as

$$W = \frac{F}{a} \times A = \frac{50 \times .07068}{.00159} = \mathbf{2222.64 \text{ N. Ans.}}$$

Problem 21.2 *A hydraulic press has a ram of 200 mm diameter and a plunger of 30 mm diameter. It is used for lifting a weight of 3 kN. Find the force required at the plunger.*

Solution. Given :

Diameter of ram, $D = 200 \text{ mm} = 0.20 \text{ m}$

$\therefore$ Area of ram, $A = \frac{\pi}{4} D^2 = \frac{\pi}{4} \times (0.20)^2 = 0.0314 \text{ m}^2$

Diameter of plunger, $d = 30 \text{ mm} = .03 \text{ m}$

$\therefore$ Area of plunger, $a = \frac{\pi}{4} (.03)^2 = 7.068 \times 10^{-4} \text{ m}^2$

Weight lifted, $W = 3 \text{ kN} = 3 \times 1000 = 3000 \text{ N}.$

Let the force on plunger $= F.$

Using relation given equation (21.1),

$$W = \frac{F}{a} \times A$$

$$F = \frac{W \times a}{A} = \frac{3000 \times 7.068 \times 10^{-4}}{.0314} = \mathbf{67.52 \text{ N. Ans.}}$$

Problem 21.3 *If in the problem 21.2, a lever is used for applying force on the plunger, find the force required at the end of the lever if the ratio l/L is 1/10.*

Solution. Given :

$D = 0.20 \text{ m}, \ A = 0.0314 \text{ m}^2$

$d = 0.03 \text{ m}, \ a = 7.068 \times 10^{-4} \text{ m}^2$

$$W = 3000 \text{ N}, \frac{l}{L} = \frac{1}{10}$$

Let F' = Force required at the end of the lever.

Using equation (21.4), $W = F' \times \frac{L}{l} \times \frac{A}{a}$

$$\therefore \quad F' = W \times \frac{l}{L} \times \frac{a}{A} = 3000 \times \frac{1}{10} \times \frac{7.068 \times 10^{-4}}{0.0314} = \textbf{6.752 N. Ans.}$$

Problem 21.4 *If in the problem 21.1, the stroke of the plunger is 100 mm, find the distance travelled by the weight in 100 strokes. Determine the work done during 100 strokes.*

Solution. The data given in problem 21.1 :

$D = 0.30$ m, $A = 0.07068$ m^2, $d = 0.045$ m, $a = .00159$ m^2

$F = 50$ N and W (calculated) = 2222.64 N

Stroke of plunger = 100 mm = 0.10 m

Number of strokes = 100

Volume of liquid displaced by plunger in one stroke

= Area of plunger × Stroke of plunger

= $a \times 0.10$ m^3 = $.00159 \times 0.10$ = .000159 m^3.

The liquid displaced by plunger will enter the cylinder in which ram is fitted and this liquid will move the ram in the upward direction.

Let the distance moved by the ram or weight in one stroke

= x m

Then volume displaced by ram in one stroke

= Area of ram × x = $A \times x = 0.07068 \times x$ m^3

As volume displaced by plunger and ram is the same,

$$\therefore \quad .000159 = .07068 \times x$$

$$\therefore \quad x = \frac{.000159}{.07068} = .00225 \text{ m}$$

$\therefore$ Distance moved by weight in 100 strokes

= $x \times 100 = .00225 \times 100 =$ **0.225 m. Ans.**

Work done during 100 strokes = Weight lifted × Distance moved

= $W \times 0.225 = 2222.64 \times 0.225$ Nm = **500.094 Nm. Ans**.

Problem 21.5 *A hydraulic press has a ram of 150 mm diameter, plunger of 20 mm diameter. The stroke of the plunger is 200 mm and weight lifted is 800 N. If the distance moved by the weight is 1.0 m in 20 minutes determine :*

(*i*) *The force applied on the plunger,* (*ii*) *Power required to drive the plunger, and*

(*iii*) *Number of strokes performed by the plunger.*

Solution. Given :

Diameter of ram, $D = 150$ mm = 0.15 m

Diameter of plunger, $d = 20$ mm = 0.02 m

Stroke of plunger = 200 mm = 0.20 m

Weight lifted, $W = 800$ N

Distance moved by weight = 1.0 m

Time taken by weight = 20 minutes

Now, area of ram, $A = \frac{\pi}{4} D^2 = \frac{\pi}{4} (.15)^2 = 0.01767 \text{ m}^2$

Area of plunger, $a = \frac{\pi}{4} (.02)^2 = .00031416 \text{ m}^2$.

(*i*) Let the force applied on the plunger = F.

Using equation (21.1), we have $W = \frac{F}{a} \times A$

$$\therefore \quad F = \frac{W \times a}{A} = \frac{800 \times .00031416}{.01767} = \textbf{14.22 N. Ans.}$$

(*ii*) Work done by the press per second

$$= \frac{\text{Weight lifted} \times \text{Distance travelled}}{\text{Time}}$$

$$= \frac{800 \times 1.0}{20 \times 60} = 0.6667 \text{ Nm/s}$$

$\therefore$ Power required to drive the plunger

$$= \frac{\text{Work done per sec}}{1000} = \frac{0.6667}{1000} = \textbf{0.000666 kW. Ans.}$$

(*iii*) Volume of liquid displaced by plunger in one stroke

= Area of plunger × Stroke length

= .00031416 × 0.20 = .000062832 m^3

Total volume of liquid displaced in cylinder

= Area of ram × Distance moved by weight

= .01767 × 1.0 = 0.01767 m^3

$\therefore$ Number of strokes performed by plunger or pump

$$= \frac{\text{Total volume of liquid displaced}}{\text{Volume of liquid displaced per stroke}}$$

$$= \frac{0.01767}{.000062832} = 281.22 \simeq \textbf{281. Ans.}$$

▶ 21.3 THE HYDRAULIC ACCUMULATOR

The hydraulic accumulator is a device used for storing the energy of a liquid in the form of pressure energy, which may be supplied for any sudden or intermittent requirement. In case of hydraulic lift or the hydraulic crane, a large amount of energy is required when lift or crane is moving upward. This energy is supplied from hydraulic accumulator. But when the lift is moving in the downward direction, no large external energy is required and at that time, the energy from the pump is stored in the accumulator.

Fig. 21.4 shows a hydraulic accumulator which consists of a fixed vertical cylinder containing a sliding ram. A heavy weight is placed on the ram. The inlet of the cylinder is connected to the pump, which continuously supplies water under pressure to the cylinder. The outlet of the cylinder is connected to the machine (which may be lift or crane etc.)

The ram is at the lowermost position in the beginning. The pump supplies water under pressure continuously. If the water under pressure is not required by the machine (lift or crane), the water under pressure will be stored in the cylinder. This will raise the ram on which a heavy weight is placed. When the ram is at the uppermost position, the cylinder is full of water and accumulator has stored the maximum amount of pressure energy. When the machine (lift or crane) requires a large amount of energy, the hydraulic accumulator will supply this energy and ram will move in the downward direction.

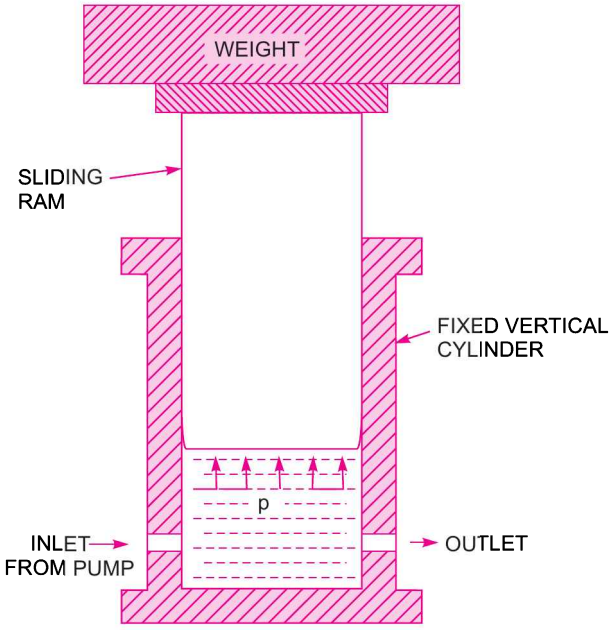

Fig. 21.4 *The hydraulic accumulator.*

21.3.1 Capacity of Hydraulic Accumulator. It is defined as the maximum amount of hydraulic energy stored in the accumulator. The expression for the capacity of accumulator is obtained as :

Let A = Area of the sliding ram,

L = Stroke or lift of the ram,

p = Intensity of water pressure supplied by the pump, and

W = Weight placed on the ram (including the weight of ram),

W = Intensity of pressure × Area of ram

Then $= p \times A$

The work done in lifting the ram $= W \times$ Lift of ram $= WL$

$= p \times A \times L$ $(W = p \times A)$

The work done in lifting the ram is also the energy stored in the accumulator. And energy stored is equal to the capacity of the accumulator.

$\therefore$ Capacity of accumulator = Work done in lifting the ram

$= p \times A \times L$ ...(21.5)

But $A \times L$ = Volume of accumulator

$\therefore$ Capacity of accumulator $= p \times$ Volume of accumulator. ...(21.6)

Problem 21.6 *Determine the length of stroke for an accumulator having a displacement of 115 litres. The diameter of the plunger is 350 mm.*

Solution. Given :

Displacement = 115 litres = 0.115 m^3

or Volume of accumulator = 0.115 m^3

Dia. of plunger, D = 350 mm = 0.35 m

$\therefore$ Area of plunger, $A = \frac{\pi}{4} D^2 = \frac{\pi}{4} \times .35^2$ m^2

But volume of accumulator $= A \times L$

where L = length of stroke.

$\therefore$ Volume $= \frac{\pi}{4} D^2 \times L$ or $0.115 = \frac{\pi}{4} \times (0.35)^2 \times L$

$\therefore$ $L = \frac{0.115 \times 4}{\pi \times 0.35^2}$ = **1.195 m. Ans.**

Problem 21.7 *The water is supplied at a pressure of 14 N/cm^2 to an accumulator, having a ram of diameter 1.5 m. If the total lift of the ram is 8 m, determine :*

(*i*) *The capacity of the accumulator, and*

(*ii*) *Total weight placed on the ram (including the weight of ram).*

Solution. Given :

Supply pressure, p = 14 N/cm^2 = 14×10^4 N/m^2

Dia. of ram, D = 1.5 m

$\therefore$ Area of ram, $A = \frac{\pi}{4} D^2 = \frac{\pi}{4} (1.5)^2 = 1.767$ m^2

Lift of ram, L = 8 m.

(*i*) Capacity of accumulator is given by equation (21.5) as

Capacity $= p \times A \times L = 14 \times 10^4 \times 1.767 \times 8$

$= 1979.04 \times 10^3$ Nm = **1979.04 kNm. Ans.**

(*ii*) Total weight (W), placed on the ram is given by

$W = p \times A = 14 \times 10^4 \times 1.767$ N = **247380 N. Ans.**

Problem 21.8 *The total weight (including the self-weight of ram) placed on the sliding ram of a hydraulic accumulator is 40 kN. The diameter of the ram is 500 mm. If the frictional resistance against the movement of the ram is 5% of the total weight, determine the intensity of pressure of water when :*

(*i*) *The ram is moving up with a uniform velocity, and*

(*ii*) *The ram is moving down with uniform velocity.*

Solution. Given :

Total weight, W = 40 kN = 40 × 1000 = 40000 N

Dia. of ram, D = 500 mm = 0.50 m

$\therefore$ Area of ram, $A = \frac{\pi}{4} D^2 = \frac{\pi}{4} (.50)^2 = 0.1963 \text{ m}^2$

Frictional resistance against the movement of ram = 5% of total weight = $\frac{5}{100} \times 40000 = 2000$ N.

(*i*) *Intensity of pressure of water when ram is moving up with a uniform velocity.* When ram is moving up, the frictional resistance is acting opposite to the direction of movement of the ram, *i.e.*, frictional resistance is acting in the downward direction. Weight is also acting in the downward direction.

$\therefore$ Total force on the ram = Total weight + Frictional resistance
= 40000 + 2000 = 42000 N.

$\therefore$ Pressure intensity (p) $= \frac{\text{Total force on ram}}{\text{Area of ram}} = \frac{42000}{0.1963}$
$= 213958 \text{ N/m}^2 =$ **21.3958 N/cm^2. Ans.**

(*ii*) *Intensity of pressure when ram is moving down with a uniform velocity.* In this case, the frictional resistance is acting in the upward direction.

$\therefore$ Total force on the ram = Total weight – Frictional resistance
= 40000 – 2000 = 38000 N

$\therefore$ Pressure intensity (p) $= \frac{\text{Total force}}{\text{Area}} = \frac{38000}{0.1963}$
$= 193581 \text{ N/m}^2 =$ **19.3581 N/cm^2. Ans.**

Problem 21.9 *If in the problem 21.8, the stroke of the ram is 10 m and the ram falls through the full stroke in 4 minutes steadily, find the work done by the accumulator per second. If the pump, connected to the inlet of the accumulator, supplies .01 m^3/s at the same time, determine the work supplied by the pump per second and also power delivered by the accumulator to the hydraulic machine, connected at the outlet of the hydraulic accumulator, when ram is moving downwards.*

Solution. The data from problem 21.8, when ram is moving downward :

Total weight = 40000 N
Frictional resistance = 2000 N
Total force on ram = Total weight – Frictional resistance
= 40000 – 2000 = 38000 N
Area, $A = 0.1963 \text{ m}^2$
Pressure intensity of water when ram is moving downward
$p = 193581 \text{ N/m}^2$
Stroke of ram, $L = 10$ m
Time taken by ram to fall through full stroke, $t = 4$ minutes $= 4 \times 60 = 240$ s
Discharge supplied $Q = .01 \text{ m}^3/\text{s}$

Distance moved by ram in one second $= \frac{\text{Stroke of ram}}{\text{Time}} = \frac{L}{t} = \frac{10}{240} = \frac{1}{24}$ m/s.

(*i*) Work done by accumulator per second
= Total force on ram × Distance moved by ram per sec
$= 38000 \times \frac{1}{24} =$ **1583.33 Nm. Ans.**

(*ii*) Work supplied by the pump per sec = Weight of water supplied by pump per second × Head of supply pressure

$$= \rho g \times Q \times H = 1000 \times 9.81 \times .01 \times H \text{ Nm}$$

where H = Pressure head of water supplied $= \dfrac{p}{\rho \times g} = \dfrac{193581}{1000 \times 9.81} = 19.733$ m

$\therefore$ Work supplied by pump per sec = $1000 \times 9.81 \times 0.01 \times 19.733$ = **1935.81 Nm. Ans.**

(*iii*) Power delivered by the accumulator to the hydraulic machine connected at the outlet of accumulator

$$= \frac{1}{1000} \text{ (Work done by accumulator per second + Work supplied by pump per second)}$$

$$= \frac{1}{1000} (1583.33 + 1935.81) = \textbf{3.519 kW. Ans.}$$

Problem 21.10 *An accumulator is loaded with 40 kN weight. The ram has a diameter of 30 cm and stroke of 6 m. Its friction may be taken as 5%. It takes two min. to fall through its full stroke. Find the total work supplied and power delivered to the hydraulic appliance by the accumulator, when 7.5 lit/s is being delivered by a pump, while the accumulator descends with the stated velocity.*

Solution. Given :

Total weight = 40 kN = $40 \times 1000 = 40000$ N

Dia. of ram, $D = 30$ cm $= 0.3$ m

$\therefore$ Area of ram, $A = \dfrac{\pi}{4} (.3)^2 = 0.07068$ m^2

Stroke of ram, $L = 6$ m

Friction = 5%

$\therefore$ Net load on accumulator (when it descends)

$$= 40000 \times 0.95 = 38000 \text{ N}$$

Time taken by ram to fall through full stroke, $t = 2$ min $= 2 \times 60 = 120$ sec

$\therefore$ Distance moved by ram per sec $= \dfrac{L}{t} = \dfrac{6}{120} = \dfrac{1}{20}$ m/s

Water supplied by pump $= 7.5$ lit/s $= \dfrac{7.5}{1000}$ m^3/s $= .0075$ m^3/s

Work supplied by accumulator per second

= Net load on ram × Distance moved by ram per sec

$$= 38000 \times \frac{1}{20} = 1900 \text{ Nm/s}$$

Intensity of pressure of water, $p = \dfrac{\text{Net load}}{\text{Area}} = \dfrac{38000}{0.07068} = 542857 \dfrac{\text{N}}{\text{m}^2}$

Head due to pressure, $H = \dfrac{p}{\rho g} = \dfrac{542857}{1000 \times 9.81} = 55.337$ m

Work supplied by pump per second = Weight of water supplied per second × Head of supplied pressure

$$= \rho g \times Q \times H = 1000 \times 9.81 \times .0075 \times 55.337 = 4071.35 \text{ Nm/s}$$

$\therefore$ Total work supplied per second to hydraulic machine

= Work supplied by accumulator and by pump

= 1900 + 4071.35 Nm/s = **5971.35 Nm/s. Ans.**

Power delivered to the hydraulic machine

$$= \frac{\text{Total work supplied per sec}}{1000} = \frac{5971.35}{1000} = \textbf{5.9713 kW. Ans.}$$

Problem 21.11 *An accumulator has a ram of diameter 250 mm and a lift of 8 m. The total weight on accumulator is 70 kN. The packing friction is 5% of the load on the ram. Find the power delivered to the machine if ram falls through the full height in 100 sec and at the same time the pumps are delivering 0.028 m^3/s through the accumulator.*

Solution. Given :

Dia. of ram, $D = 250 \text{ mm} = 0.25 \text{ m}$

$\therefore$ Area of ram, $A = \frac{\pi}{4}(.25)^2 = \frac{\pi}{64} \text{ m}^2$

Lift of ram, $L = 8 \text{ m}$

Total weight $= 70 \text{ kN} = 70 \times 1000 = 70000 \text{ N}$

Packing friction = 5% of 70000 $= \frac{5}{100} \times 70000 = 3500 \text{ N}$

$\therefore$ Net load on accumulator, when the ram is moving downwards

$= 70000 - 3500 = 66500 \text{ N}$

Time taken by ram to fall through 8 m, $t = 100$ sec

Water supplied by pump, $Q = 0.028 \text{ m}^3/\text{s}$.

When ram is moving downwards, the pressure intensity (p) is given by,

$$p = \frac{\text{Net load}}{\text{Area}} = \frac{66500}{\left(\frac{\pi}{64}\right)} = \frac{66500 \times 64}{\pi} \text{ N/m}^2$$

Head corresponding to the above pressure intensity,

$$h = \frac{p}{\rho g} = \frac{66500 \times 4}{1000 \times 9.81 \times \pi} = 138.09 \text{ m of water.}$$

Power delivered by pump $= \frac{\rho g . Q . H}{1000} = \frac{1000 \times 9.81 \times 0.028 \times 138.09}{1000} = 37.931 \text{ kW}$

Power supplied by accumulator $= \frac{\text{Net load on ram} \times \text{Lift}}{1000 \times \text{Time}} = \frac{66500 \times 8}{1000 \times 100} = 5.32 \text{ kW.}$

$\therefore$ Total power $= 37.931 + 5.32 = \textbf{43.251 kW. Ans.}$

21.3.2 Differential Hydraulic Accumulator.

It is a device in which the liquid is stored at a high pressure by a comparatively small load on the ram. It consists of a fixed vertical cylinder of small diameter as shown in Fig. 21.5. The fixed vertical cylinder is surrounded by closely fitting brass bush, which is surrounded by an inverted moving cylinder, having circular projected collar at the base on which weights are placed.

The liquid from the pump is supplied to the fixed vertical cylinder. The liquid moves up through the small diameter of fixed vertical cylinder and then enters the inverted cylinder. The water exerts an upward pressure force on the internal annular area of the inverted moving cylinder, which is loaded at the base. The internal annular area of the inverted moving cylinder is equal to the sectional area of the brass bush. When the inverted moving cylinder moves up, the hydraulic energy is stored in the accumulator.

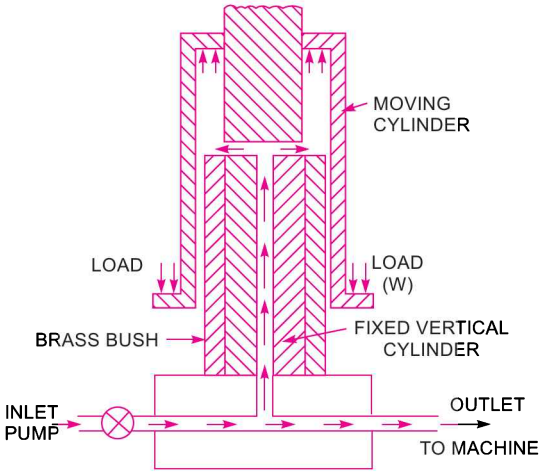

Fig. 21.5 *Differential hydraulic accumulator.*

Let p = Intensity of pressure of liquid supplied by pump,

a = Area of brass-bush,

L = Vertical lift of the moving cylinder,

W = Total weight placed on the moving cylinder including the weight of cylinder.

Then $W = p \times a$

$\therefore$ $$P = \frac{W}{a} \qquad ...(21.7)$$

From equation (21.7), it is clear that pressure intensity can be increased with a small load W, by making area 'a' small.

Now total energy stored in the accumulator = Total weight × Vertical lift

$$= W \times L \text{ Nm.} \qquad ...[21.7\ (a)]$$

▶ 21.4 THE HYDRAULIC INTENSIFIER

The device, which is used to increase the intensity of pressure of water by means of hydraulic energy available from a large amount of water at a low pressure, is called the hydraulic intensifier. Such a device is needed when the hydraulic machines such as hydraulic press requires water at very high pressure which cannot be obtained from the main supply directly.

A hydraulic intensifier consists of fixed ram through which the water, under a high pressure, flows to the machine. A hollow inverted sliding cylinder, containing water under high pressure, is mounted over the fixed ram. The inverted sliding cylinder is surrounded by another fixed inverted cylinder which contains water from the main supply at a low pressure as shown in Fig. 21.6

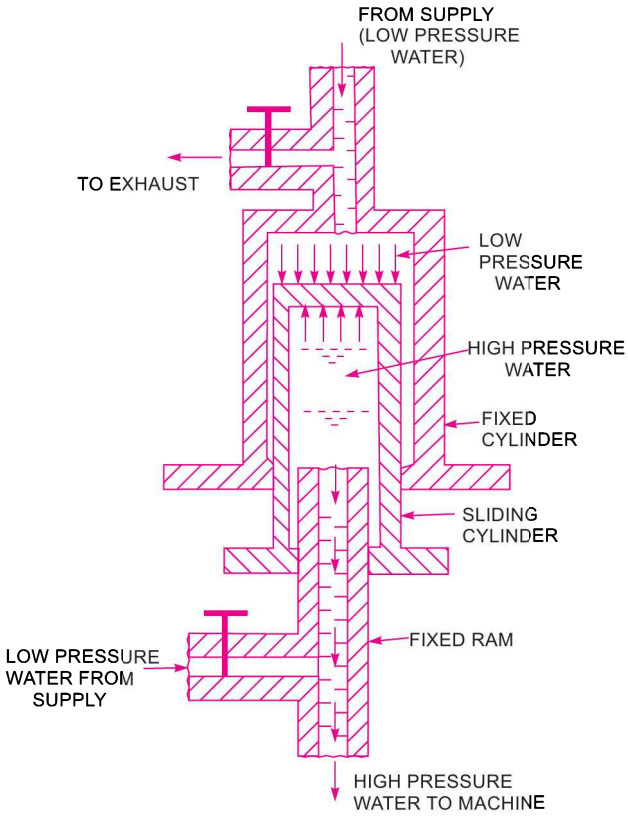

Fig. 21.6 *The hydraulic intensifier.*

A large quantity of water at low pressure from supply enters the inverted fixed cylinder. The weight of this water pressure the sliding cylinder in the downward direction. The water in the sliding cylinder gets compressed due to the downward movement of the sliding cylinder and its pressure is thus increased. The high pressure water is forced out of the sliding cylinder through the fixed ram, to the machine as shown in Fig. 21.6.

Let p = Intensity of pressure of water from supply to the fixed cylinder (low pressure water),

A = External area of the sliding cylinder,

a = Area of the end of the fixed ram, and

p^* = Intensity of the pressure of water in the sliding cylinder (high pressure water).

The force exerted by low pressure water on the sliding cylinder in the downward direction

$$= p \times A.$$

The force exerted by the high pressure water on the sliding cylinder in the upward direction

$$= p^* \times a.$$

Equating the upward and downward forces,

$$p \times A = p^* \times a.$$

$$p^* = \frac{p \times A}{a}. \qquad \text{...(21.8)}$$

Problem 21.12 *The diameters of fixed ram and fixed cylinder of an intensifier are 8 cm and 20 cm respectively. If the pressure of the water supplied to the fixed cylinder is 300 N/cm^2, find the pressure of the water flowing through the fixed ram.*

Solution. Given :

Dia. of fixed ram, $d = 8$ cm

$\therefore$ Area of fixed ram, $a = \frac{\pi}{4} d^2 = \frac{\pi}{4} \times 8^2 = 16\ \pi\ \text{cm}^2$

Dia. of fixed cylinder, $D = 20$ m

$\therefore$ Area of fixed cylinder, $A = \frac{\pi}{4} \times 20^2 = 100\ \pi\ \text{cm}^2$

Intensity of supply pressure, $p = 300\ \text{N/cm}^2$

Let the intensity of pressure of water flowing through fixed ram $= p^*$

Using equation (21.8), $p^* = \frac{p \times A}{a} = \frac{300 \times 100\pi}{16\pi} = \mathbf{1875\ N/cm^2.\ Ans.}$

Problem 21.13 *The pressure intensity of water supplied to an intensifier is 20 N/cm^2 while the pressure intensity of water leaving the intensifier is 100 N /cm^2. The external diameter of the sliding cylinder is 20 cm. Find the diameter of the fixed ram of the intensifier.*

Solution. Given :

Supply pressure, $p = 20\ \text{N/cm}^2$

Intensity of pressure leaving the intensifier, $p^* = 100\ \text{N/cm}^2$

External dia. of sliding cylinder, $D = 20$ cm

$\therefore$ Area of sliding cylinder, $A = \frac{\pi}{4} \times 20^2 = 100\ \pi\ \text{cm}^2$

Let the dia. of the fixed ram $= d$

$\therefore$ Area of the fixed ram, $a = \frac{\pi}{4} d^2$

Using equation (21.8), $p^* = \frac{p \times A}{a}$

$$100 = \frac{20 \times 100\pi}{\frac{\pi}{4} d^2} = \frac{20 \times 100 \times 4}{d^2}$$

$\therefore$ $$d = \sqrt{\frac{20 \times 100 \times 4}{100}} = \sqrt{80} = \mathbf{8.94\ cm.\ Ans.}$$

▶ 21.5 THE HYDRAULIC RAM

The hydraulic ram is a pump which raises water without any external power for its operation. When large quantity of water is available at a small height, a small quantity of water can be raised to a greater height with the help of hydraulic ram. It works on the principle of water hammer.

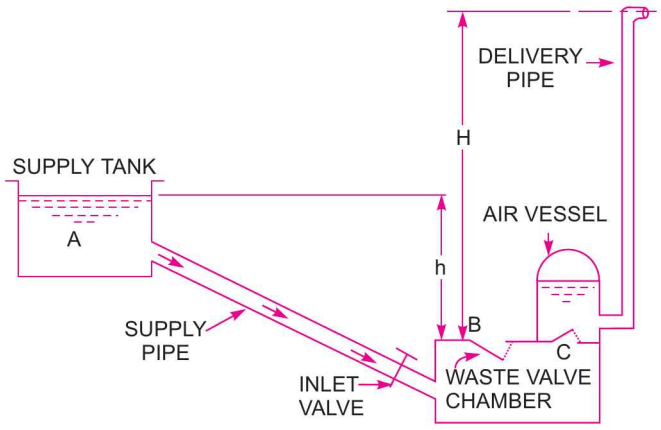

Fig. 21.7 *The hydraulic ram.*

Fig. 21.7 shows the main components of the hydraulic ram. When the inlet valve fitted to the supply pipe is opened, water starts flowing from the supply tank to the chamber, which has two valves at *B* and *C*. The valve *B* is called waste valve and valve *C* is called the delivery valve. The valve *C* is fitted to an air vessel. As the water is coming into the chamber from supply tank, the level of water rises in the chamber and waste valve *B* starts moving upward. *A* stage comes, when the waste valve *B* suddenly closes. This sudden closure of waste valve creates high pressure inside the chamber. This high pressure force opens the delivery valve *C*. The water from chamber enters the air vessel and compresses the air inside the air vessel. This compressed air exerts force on the water in the air vessel and small quantity of water is raised to a greater height as shown in Fig. 21.7.

When the water in the chamber loses its momentum, the waste valve *B* opens in the downward direction and the flow of water from supply tank starts flowing to the chamber and the cycle will be repeated.

Let W = Weight of water flowing per second into chamber,

w = Weight of water raised per second,

h = Height of water in supply tank above the chamber,

H = Height of water raised from the chamber.

The energy supplied by the supply tank to ram

= Weight of water supplied × Height of supply water

$= W \times h$ ...(*i*)

Energy delivered by the ram = Weight of water raised × Height through which water is raised

$= w \times H$ ...(*ii*)

∴ Efficiency of the hydraulic ram,

$$\eta = \frac{\text{Energy delivered by the ram}}{\text{Energy supplied to the ram}} = \frac{w \times H}{W \times h} \qquad ...(21.9)$$

The above expression of efficiency was given by D' Aubuisson and hence known as *D' Aubuisson's efficiency*.

Rankine gave another form of the above efficiency. According to him, the weight of water (w) is raised to a height of ($H - h$) and not H. The water is initially at a height of h from the ram and hence the water is only raised to a height equal to ($H - h$). Hence according to Rankine :

Energy delivered by the ram $= w \times (H - h)$

Energy supplied $= (W - w)\, h$

$\therefore$ Efficiency, $$\eta = \frac{w \times (H - h)}{(W - w) \times h} \qquad ...(21.10)$$

Equation (21.10) is known as *Rankine's efficiency.*

The above two efficiencies, in terms of discharge is written as,

D' Aubuisson's $$\eta = \frac{q \times H}{Q \times h} \qquad ...(21.11)$$

Rankine's $$\eta = \frac{q(H - h)}{(Q - q) \times h} \qquad ...(21.12)$$

where q = Discharge of delivery pipe,

Q = Discharge through supply pipe.

Problem 21.14 *The water is supplied at the rate of 0.02 m^3 per second from a height of 3 m to a hydraulic ram, which raises 0.002 m^3/s to a height of 20 m from the ram. Determine D' Aubuisson's and Rankine's efficiencies of the hydraulic ram.*

Solution. Given :

Discharge through supply pipe, $Q = 0.02$ m^3/s

Supply head, $h = 3$ m

Discharge raised, $q = 0.002$ m^3/s

Height of water raised from hydraulic ram, $H = 20$ m

Using equation (21.11),

D' Aubuisson's $$\eta = \frac{q \times H}{Q \times h} = \frac{.002 \times 20}{.02 \times 3} = .6667 = \mathbf{66.67\%.\ Ans.}$$

Rankine's efficiency is given by equation (21.12) as

Rankine's $$\eta = \frac{q(H - h)}{(Q - q) \times h}$$

$$= \frac{0.002 \times (20 - 3)}{(0.020 - .0002) \times 3} = \frac{0.002 \times 17}{.018 \times 3} = 0.6296 = \mathbf{62.96\%.\ Ans.}$$

Problem 21.15 *The water is supplied at the rate of 3000 litres per minute from a height of 4 m to a hydraulic ram, which raises 300 litres/minute to a height of 30 m from the ram. The length and diameter of the delivery pipe is 100 m and 70 mm respectively. Calculate the efficiency of the hydraulic ram if the co-efficiency of friction f = .009.*

Solution. Given :

Discharge supplied, $Q = 3000$ litres/minute

$$= \frac{3000}{60} \text{ lit/s} = \frac{3000}{60 \times 1000} \text{m}^3\text{/s} = 0.05 \text{ m}^3\text{/s}$$

Supply head, $h = 4$ m

Discharge raised, $q = 300$ lit/min $= \dfrac{0.3}{60} = .005$ m^3/s ($\because$ 300 lit = 0.3 m^3)

Height of water raised from hydraulic ram, $H = 30$ m

Length of delivery pipe, $L = 100$ m

Dia. of delivery pipe, $d = 70$ mm $= .07$ m

Co-efficient of friction, $f = .009$

Head lost due to friction in delivery pipe is

$$h_f = \frac{4fLV^2}{d \times 2g} = \frac{4 \times .009 \times 100 \times V^2}{.07 \times 2 \times 9.81} \quad ...(i)$$

But V = Velocity of water in delivery pipe

$$= \frac{\text{Discharge in delivery pipe}}{\text{Area}}$$

$$= \frac{q}{\frac{\pi}{4}d^2} = \frac{0.005}{\frac{\pi}{4} \times (.07)^2} = 1.299 \simeq 1.3 \text{ m/s.}$$

Substituting this value of V in equation (i), we get

$$h_f = \frac{4 \times .009 \times 100 \times (1.3)}{.07 \times 2 \times 9.81} = 4.43 \text{ m}$$

$\therefore$ Effective head developed by the ram

$$= H + h_f = 30 + 4.43 = 34.43 \text{ m}$$

D' Aubuisson's efficiency is given by equation (21.11), as

$$\eta = \frac{q \times \text{Effective head}}{Q \times h} \quad \text{(Here } H \text{ = Effective head)}$$

$$= \frac{.005 \times 34.43}{0.05 \times 4} = 0.8607 = \mathbf{86.07\%. \text{ Ans.}}$$

Rankine's efficiency is given by equation (21.12) as

$$\eta = \frac{q(\text{Effective head} - h)}{(Q - q) \times h}$$

$$= \frac{.005\,(34.43 - 4.0)}{(.05 - .005) \times 4.0} = \frac{.005 \times 30.43}{.045 \times 4.0} = 0.8453 = \mathbf{84.53\%. \text{ Ans.}}$$

▶ 21.6 THE HYDRAULIC LIFT

The hydraulic lift is a device used for carrying passenger or goods from one floor to another in multi-storeyed building. The hydraulic lifts are of two types, namely,

1. Direct acting hydraulic lift, and 2. Suspended hydraulic lift.

21.6.1 Direct Acting Hydraulic Lift. It consists of a ram, sliding in fixed cylinder as shown in Fig. 21.8. At the top of the sliding ram, a cage (on which the persons may stand or goods may be placed) is fitted. The liquid under pressure flows into the fixed cylinder. This liquid exerts force on the sliding ram, which moves vertically up and thus raises the cage to the required height.

The cage is moved in the downward direction, by removing the liquid from the fixed cylinder.

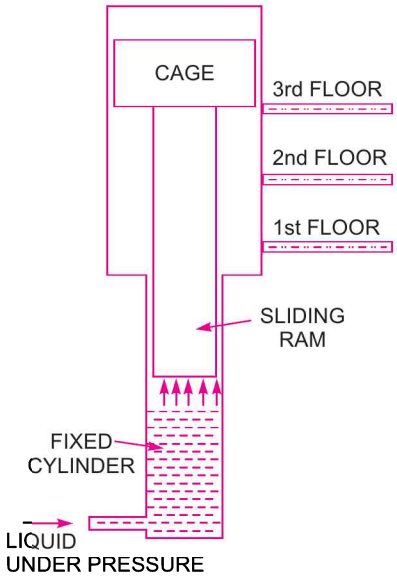

Fig. 21.8 *Suspended hydraulic lift.*

21.6.2 Suspended Hydraulic Lift. Fig. 21.9 shows the suspended hydraulic lift. It is a modified form of the direct acting hydraulic lift. It consists of a cage (on which persons may stand or goods may be placed) which is suspended from a wire rope. A jigger, consisting of a fixed cylinder, a sliding ram and a set of two pulley blocks, is provided at the foot of the hole of the cage. One of the pulley block is movable and the other is a fixed one. The end of the sliding ram is connected to the movable pulley block. A wire rope, one end of which is fixed at *A* and the other end is taken round all the pulleys of the movable and fixed blocks and finally over the guide pulleys as shown in Fig. 21.9. The cage is suspended from the other end of the rope. The raising or lowering of the cage of the lift is done by the jigger as explained below.

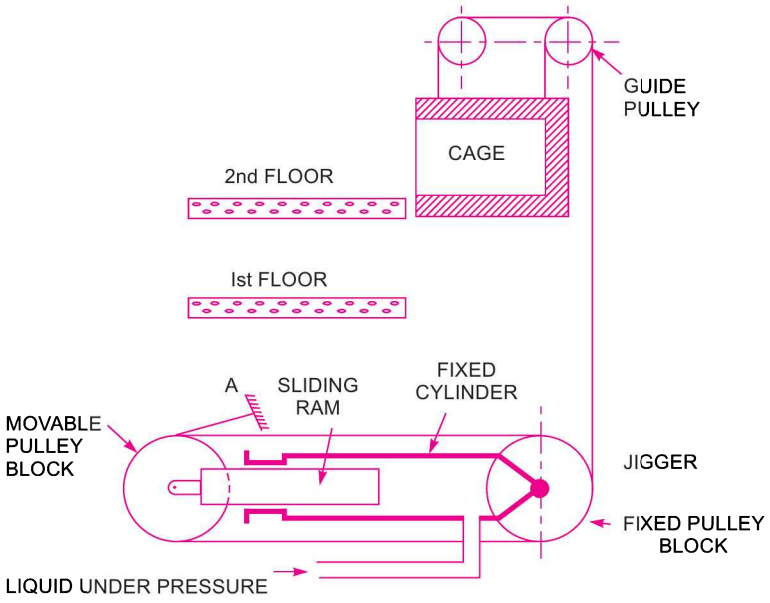

Fig. 21.9 *Suspended hydraulic lift.*

When water under high pressure is admitted into the fixed cylinder of the jigger, the sliding ram is forced to move towards left. As one end of the sliding ram is connected to the movable pulley block and hence the movable pulley block moves towards the left, thus increasing the distance between two

pulley blocks. The wire rope connected to the cage is pulled and the cage is lifted. For lowering the cage, water from the fixed cylinder is taken out. The sliding ram moves towards right and hence movable pulley blocks also moves towards right. This decreases the distance between two pulley blocks and the cage is lowered due to increased length of the rope.

Problem 21.16 *A hydraulic lift is required to lift a load of 8 kN through a height of 10 metres, once in every 80 seconds. The speed of the lift is 0.5 m per second. Determine :*

(i) Power required to drive the lift, (ii) Working period of lift in seconds, and

(iii) Idle period of the lift in seconds.

Solution. Given :

Load lifted, $W = 8 \text{ kN} = 8 \times 1000 = 8000 \text{ N}$

Height, $H = 10 \text{ m}$

Time for one operation, $t = 80 \text{ s}$

Speed of lift, $v = 0.5 \text{ m/s}$.

(*i*) Work done in lifting the load in 80 seconds

$$= W \times H = 8000 \times 10 = 80000 \text{ Nm}$$

$\therefore$ Work done/s $= \dfrac{80000}{80} = 1000 \text{ Nm/s}$

$\therefore$ Power required to drive the lift $= \dfrac{1}{1000} \times \text{Work done/s} = \dfrac{1}{1000} \times 1000 =$ **1.0 kW. Ans.**

(*ii*) Working period of the lift $= \dfrac{\text{Height of the lift}}{\text{Velocity of lift}} = \dfrac{10}{0.50} =$ **20 sec. Ans.**

(*iii*) Idle period of the lift = Total time – Working period of lift

$= 80 - 20 =$ **60 sec. Ans.**

Problem 21.17 *A hydraulic lift is required to lift a load of 12 kN through a height of 10 m, once in every 1.75 minutes. The speed of the lift is 0.75 m/s. During working stroke of the lift, water from accumulator and the pump at a pressure of 400 N/cm^2 is supplied to the lift. If the efficiency of the pump is 8% and that of lift is 75%, find the power required to drive the pump and the minimum capacity of the accumulator. Neglect friction losses in the pipe.*

Solution. Given :

Load lifted, $W = 12 \text{ kN} = 12 \times 1000 = 12000 \text{ N}$

Height, $H = 10 \text{ m}$

Total time for one operation, $t = 1.75 \text{ min} = 1.75 \times 60 = 105 \text{ s}$

Speed of lift, $v = 0.75 \text{ m/s}$

Water pressure from accumulator and pump,

$$p = 400 \text{ N/cm}^2 = 400 \times 10^4 \text{ N/m}^2$$

Efficiency of pump, $\eta_p = 80\% = 0.80$

Efficiency of lift, $\eta_l = 75\% = 0.75$

Work done by water (supplied from accumulator and pump) in raising lift per second

$$= \text{Load lifted} \times \text{Distance travelled per s}$$

$$= W \times \text{Velocity of lift}$$

$$= W \times v = 12000 \times 0.75 = 9000 \text{ Nm/s}$$

$\therefore$ Useful power $= \dfrac{\text{Work done per second}}{1000} = \dfrac{9000}{1000} = 9 \text{ kW}$

$\therefore$ Actual power supplied to lift $= \dfrac{\text{Useful horse power}}{\eta_l} = \dfrac{9.0}{0.75} = 12$ kW.

The power 12 kW has been supplied by the pump and by accumulator to the lift.

Let P_1 = Output of the pump in kW

Then $(12 - P_1)$ = Output of the accumulator in kW ...(*i*)

Now, working period of the lift $= \dfrac{\text{Height of lift}}{\text{Velocity of lift}} = \dfrac{H}{v} = \dfrac{10}{0.75} = 13.33$ s

Idle period of lift = Total time – Working period of lift

= 105 – 13.33 = 91.67 s

Thus during idle period of lift, the energy will be stored in the accumulator and during working period of lift of 13.33 s, the energy will be supplied by the accumulator to the lift.

$\therefore$ Energy stored during idle period in accumulator

= Output of pump × Idle period

$= (P_1 \times 1000) \times 91.67$ Nm/s ($\because$ 1 kW = 1000 Nm/s) ...(*ii*)

The above energy is supplied by accumulator in 13.33 seconds.

$\therefore$ Energy supplied by accumulator per second

$$= \frac{(P_1 \times 1000) \times 91.67}{13.33} \text{ Nm/s}$$

$\therefore$ Power supplied by accumulator $= \dfrac{1}{1000}$ [Energy supplied by accumulator per second]

$$= \frac{1}{1000}\left[\frac{P_1 \times 1000 \times 91.67}{13.33}\right] = 6.877\, P_1.$$

But from equation (*i*), power supplied by accumulator is also

$= (12 - P_1)$

$\therefore$ Equating the two values of power supplied by accumulator,

$6.877\, P_1 = 12 - P_1$ or $6.877\, P_1 + P_1 = 12$ or $7.877\, P_1 = 12$

$\therefore$ $P_1 = \dfrac{12}{7.877} = 1.523.$

But we have assumed P_1 as the output of the pump.

$\therefore$ Input to the pump $= \dfrac{\text{Output}}{\text{Efficiency of pump}} = \dfrac{P_1}{\eta_p} = \dfrac{1.523}{0.80} = 1.90375$ kW.

(*i*) $\therefore$ Power required to drive the pump = **1.90375 kW. Ans.**

(*ii*) Minimum capacity of the accumulator.

From equation (*ii*), the energy stored in the accumulator

$= P_1 \times 1000 \times 91.67$ Nm

$= 1.523 \times 1000 \times 91.67$ Nm ($\because$ $P_1 = 1.523$)

= 139613.4 Nm.

The capacity of the accumulator means the amount of hydraulic energy stored in the accumulator.

$\therefore$ Minimum capacity of accumulator = Energy stored = **139613.4 Nm. Ans.**

▶ 21.7 THE HYDRAULIC CRANE

Hydraulic crane is a device, used for raising or transferring heavy loads. It is widely used in workshops, warehouses and dock sidings.

A hydraulic crane consists of a mast, tie, jib, guide pulley and a jigger. The jib and tie are attached to the mast. The jib can be raised or lowered in order to decrease or increase the radius of action of the crane. The mast along with the jib can revolve about a vertical axis and thus the load attached to the rope can be transferred to any place within the area of the crane's action. The jigger, which consists of a movable ram sliding in a fixed cylinder, is used for lifting or lowering the heavy loads. One end of the ram is in contact with water and the other end is connected to set of movable pulley block. Another pulley block, called the fixed pulley block is attached to the fixed cylinder. The pulley block, attached to the ram, moves up and down while the pulley block, attached to the fixed cylinder, is not having any movement.

A wire rope, one end of which is fixed to a movable pulley (which is attached to the sliding ram) is taken round all the pulleys of the two sets of the pulleys and finally passes over the guide pulley, attached to the jib as shown in Fig. 21.10. The other end of the rope is provided with a hook, for suspending the load.

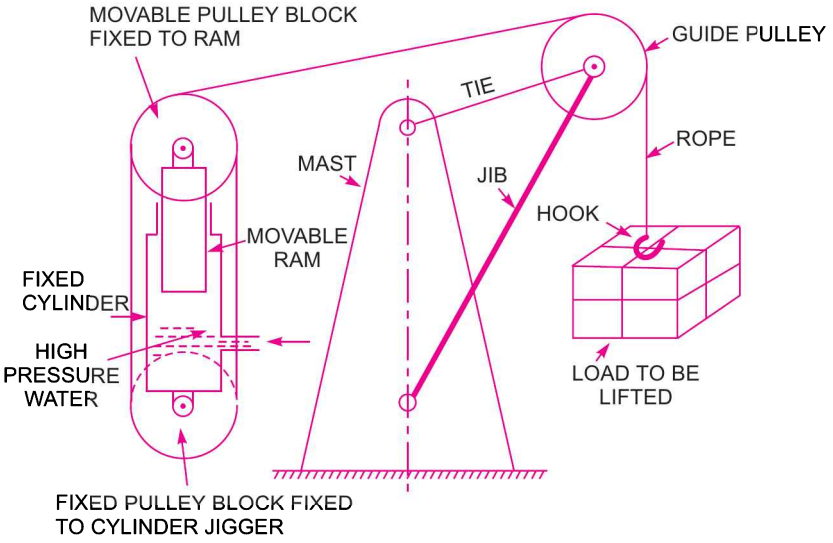

Fig. 21.10 *The hydraulic crane.*

For lifting the load by the crane, the water under high pressure is admitted into the cylinder of the jigger. This water forces the sliding ram to move vertically up. Due to the movement of the ram in the vertically up direction, the movable pulley block attached to the ram also moves upward. This increases the distance between two pulley blocks and hence the wire passing over the guide pulley is pulled by the jigger. This raises the load attached to the hook.

Problem 21.18 *Find the efficiency of a hydraulic crane, which is supplied 300 litres of water under a pressure of 60 N/cm^2 for lifting a weight of 12 kN through a height of 11 m.*

Solution. Given :

Water supplied, $Q = 300 \text{ litres} = 0.30 \text{ m}^3$

Pressure, $p = 60 \text{ N/cm}^2 = 60 \times 10^4 \frac{\text{N}}{\text{m}^2}$

Weight lifted, $W = 12 \text{ kN} = 12 \times 1000 = 12000 \text{ N}$

Height, $h = 11 \text{ m}$

Output of the crane = Weight lifted × Height through which weight is lifted

$= W \times h = 12000 \times 11 \text{ Nm}$

Input of the crane = Energy supplied by the water

= Work done by water on the ram

= Force on ram × Distance moved by ram

= Pressure × Area of ram × Stroke of ram

$= p \times A \times L$

$= 60 \times 10^4 \times$ Volume displaced

$= 60 \times 10^4 \times 0.30$ $(\because \quad A \times L = Q)$

$= 18 \times 10^4 \text{ Nm}$

$\therefore$ Efficiency of the crane $= \dfrac{\text{Output}}{\text{Input}} = \dfrac{12000 \times 11}{18 \times 10^4} = 0.7333 =$ **73.33%. Ans.**

Problem 21.19 *The efficiency of a hydraulic crane, which is supplied water under a pressure of 70 N/cm^2 for lifting a weight through a height of 10 m, is 60%. If the diameter of the ram is 150 mm and velocity ratio is 6, find*

(*i*) *the weight lifted by the crane, and*

(*ii*) *the volume of water required in litres to lift the weight.*

Solution. Given :

Efficiency, $\eta = 60\% = 0.60$

Pressure of water, $p = 70 \text{ N/cm}^2 = 70 \times 10^4 \text{ N/m}^2$

Height through which weight is lifted, $h = 10 \text{ m}$

Diameter of the ram, $D = 150 \text{ mm} = 0.15 \text{ m}$

$\therefore$ Area of ram, $A = \dfrac{\pi}{4} (.15)^2 = 0.01767 \text{ m}^2$

Velocity ratio = 6

Pressure force on ram, P = Pressure × Area of ram

$= p \times A = 70 \times 10^4 \times 0.01767 = 12369 \text{ N}.$

(*i*) We know efficiency of the hydraulic crane is given as

$$\eta = \frac{\text{Output}}{\text{Input}} = \frac{\text{Weight} \times \text{Distance moved by weight}}{\text{Force} \times \text{Distance moved by force}}$$

or $$0.60 = \frac{W \times \text{Distance moved by weight}}{P \times \text{Distance moved by force}}$$

But $\dfrac{\text{Distance moved by weight}}{\text{Distance moved by force}} = \text{Velocity ratio} = 6$

$\therefore$ $$0.60 = \frac{W}{P} \times 6 = \frac{W}{12369} \times 6$$

$\therefore$ $$W = \frac{0.60 \times 12369}{6} = \textbf{1236.9 N. Ans.}$$

(*ii*) Volume of water required to lift the weight :

$$\text{Velocity ratio} = \frac{\text{Distance moved by weight}}{\text{Distance moved by force on ram}}$$

or $$6 = \frac{h}{\text{Stroke of ram}} \quad (\because \text{ Distance moved by ram = Stroke of ram})$$

$\therefore$ Stroke of ram, $L = \frac{h}{6} = \frac{10}{6} = 1.667$ m

$\therefore$ Volume of water = Area of ram × Stroke of ram = $A \times L = 0.01767 \times 1.667$

$= 0.02945 \text{ m}^3 = 0.02945 \times 1000 =$ **29.45 litres. Ans.**

Problem 21.20 *A hydraulic crane is lifting a weight of 12000 N through a height of 12 m with a speed of 18 m per minute once in every two minutes. The efficiency of the hydraulic crane is 65% and it is working under a pressure of 500 N/cm^2 of water. The crane is fed from an accumulator to which water is supplied by a pump. Find :*

(*i*) *the capacity of the cylinder of the jigger in litres,*

(*ii*) *the capacity of the accumulator in litres, and*

(*iii*) *minimum power required for the pump.*

Solution. Given :

Weight lifted, $W = 12000$ N

Height, $h = 12$ m

Speed of weight, $V = 18$ m/min

No. of times the weight if lifted = Once in every two minutes

Efficiency, $\eta = 65\% = 0.65$

Pressure of water, $p = 500 \text{ N/cm}^2 = 500 \times 10^4 \text{ N/m}^2$

(*i*) Output of the crane = Weight lifted × Height

$= W \times h = 12000 \times 12 = 144000$ Nm.

Input of the crane = Work done by water on ram

= Force on ram × Distance moved by ram

$= p \times A \times L$

$= p \times$ Volume of cylinder $(\because \ A \times L =$ Volume of cylinder)

$= 500 \times 10^4 \times$ Volume of cylinder

$\therefore \quad \eta = \frac{\text{Output}}{\text{Input}} = \frac{144000}{500 \times 10^4 \times \text{volume of cylinder}}$

$\therefore$ Volume of cylinder $= \frac{144000}{500 \times 10^4 \times \eta} = \frac{144000}{500 \times 10^4 \times 0.65} = 0.0443 \text{ m}^3 = 44.3$ litres.

$\therefore$ Capacity of the cylinder of the jigger = **44.3 litres. Ans.**

(*ii*) Input of the crane $= p \times$ Volume of cylinder $= 500 \times 10^4 \times 0.0443 = 221500$ Nm.

This input is given to the crane once in every two minutes.

$\therefore$ Input to crane per min. $= \frac{221500}{2} = 110750$ Nm.

The weight 12000 N is lifted to a height of 12 m with a speed of 18 m/min.

Time required to lift the weight through height of 12 m $= \frac{\text{Height}}{\text{Speed}} = \frac{12}{18} = \frac{2}{3}$ min.

$\therefore$ Work done by the pump during lifting

= Work done per min. × Time required to lift the weight

$= 110750 \times \frac{2}{3} = 73833.33$ Nm

$\therefore$ Energy supplied by accumulator = Total input energy to the crane – Work done during lifting

$= 221500 - 73833.33 = 147666.67$ Nm ...(*i*)

But energy supplied by accumulator = Force on the ram of accumulator × Lift of ram

$= p \times A \times H = p \times$ Capacity of accumulator

$= 500 \times 10^4 \times$ Capacity of accumulator ...(*ii*)

Equating the two values given by equations (*i*) and (*ii*),

$147666.67 = 500 \times 10^4 \times$ Capacity of accumulator

$\therefore$ Capacity of accumulator $= \frac{147666.67}{500 \times 10^4} = 0.0295 \text{ m}^3 =$ **29.5 litres. Ans.**

(*iii*) Minimum power required for the pump

$= \frac{\text{Work input per minute}}{1000 \times 60} = \frac{110750}{1000 \times 60} =$ **1.846 kW. Ans.**

▶ 21.8 THE FLUID OR HYDRAULIC COUPLING

The fluid or hydraulic coupling is a device used for transmitting power from driving shaft to driven shaft with the help of fluid (generally oil). There is no mechanical connection between the two shafts. It consists of a radial pump impeller mounted on a driving shaft *A* and a radial flow reaction turbine mounted on the driven shaft *B*. Both the impeller and runner are identical in shape and they together form a casing which is completely enclosed and filled with oil.

In the beginning, both the shafts *A* and *B* are at rest. When the driving shaft *A* is rotated, the oil starts moving from the inner radius to the outer radius of the pump impeller as shown in Fig. 21.11. The pressure energy and kinetic energy of the oil increases at the outer radius of the pump impeller. This oil of increased energy enters the runner of the reaction turbine at the outer radius of the turbine runner and flows inwardly to the inner radius of the turbine runner. The oil, while flowing through the runner, transfers its energy to the blades of the runner and makes the runner to rotate. The oil, from the runner then flows back into the pump impeller, thus having a continuous circulation.

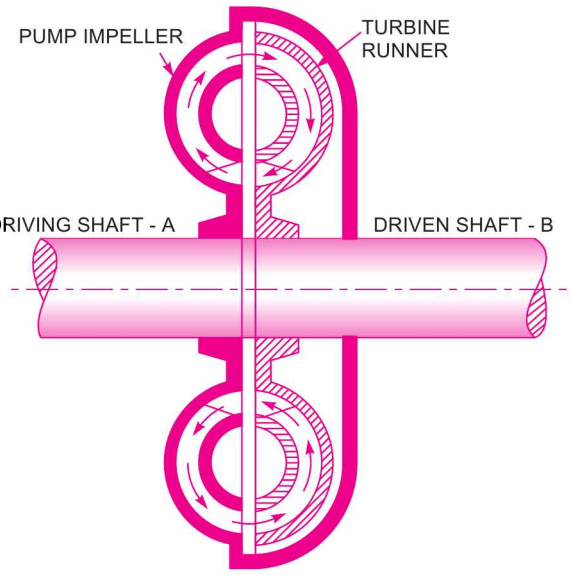

Fig. 21.11 *The hydraulic coupling.*

The power is transmitted hydraulically from the driving shaft to driven shaft and the driven shaft is free from engine vibrations. The speed of the driven shaft B is always less than the speed of the shaft A, by about 2 per cent. The efficiency of the power transmission by hydraulic coupling is about 98%. This is derived as given below.

$$\text{Efficiency of a fluid coupling} = \frac{\text{Power output}}{\text{Power input}}$$

or
$$\eta = \frac{\text{Power transmitted to shaft } B}{\text{Power available at shaft } A} \qquad ...(i)$$

But power at any shaft $= \dfrac{2\pi NT}{60{,}000} \propto NT \propto \text{Speed} \times \text{Torque}$

Let N_A = Speed of shaft A, ...(*ii*)

T_A = Torque at the shaft A,

N_B = Speed of shaft B,

T_B = Torque transmitted to shaft B.

From equation (*ii*), we have

Power available to shaft $A \propto$ (Speed of shaft A) $\times$ Torque of A

$$\propto N_A \times T_A.$$

Similarly, power transmitted to shaft $B \propto N_B \times T_B$.

Substituting these values of powers in equation (*ii*),

$$\eta = \frac{N_B \times T_B}{N_A \times T_A}$$

But $T_A = T_B$ ($\because$ Torque transmitted is same)

$$\therefore \quad \eta = \frac{N_B}{N_A} \qquad ...(21.13)$$

Slip of fluid coupling is defined as the ratio of the difference of the speeds of the driving and driven shaft to the speed of the driving sharp. Mathematically,

Slip, $$S = \frac{N_A - N_B}{N_A} = 1 - \frac{N_B}{N_A} = 1 - \eta \qquad \left(\because \frac{N_B}{N_A} = \eta\right) \qquad ...(21.14)$$

▶ 21.9 THE HYDRAULIC TORQUE CONVERTER

The hydraulic torque converter is a device used for transmitting increased torque at the driven shaft. The torque transmitted at the driven shaft may be more or less than the torque available at the driving shaft. The torque at the driven shaft may be increased about five times the torque available at the driving shaft with an efficiency of about 90%.

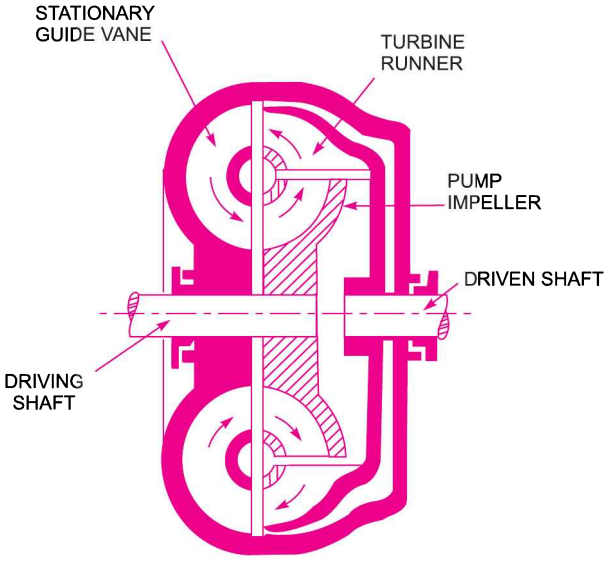

Fig. 21.12 *Fluid of hydraulic torque converter.*

As mentioned in Art. 21.8, the power at any shaft is proportional to the product of torque and speed of the shaft. Hence, if the torque at the driven shaft is to be increased, the corresponding value of the speed at the same shaft should be decreased. The speed of the driven shaft is decreased by decreasing the velocity of oil, which is allowed to flow from the pump impeller to the turbine runner and then through stationary guide vanes as shown in Fig. 21.12. Due to the decrease in speed at the driven shaft, the torque increases.

▶ 21.10 THE AIR LIFT PUMP

The air lift pump is a device which is used for lifting water from a well or sump by using compressed air. The compressed air is made to mix with the water. The density of the mixture of air and water is reduced. The density of this mixture is much less than that of pure water. Hence a very small column of pure water can balance a very long column of air water mixture. This is the principle on which the air lift pump works.

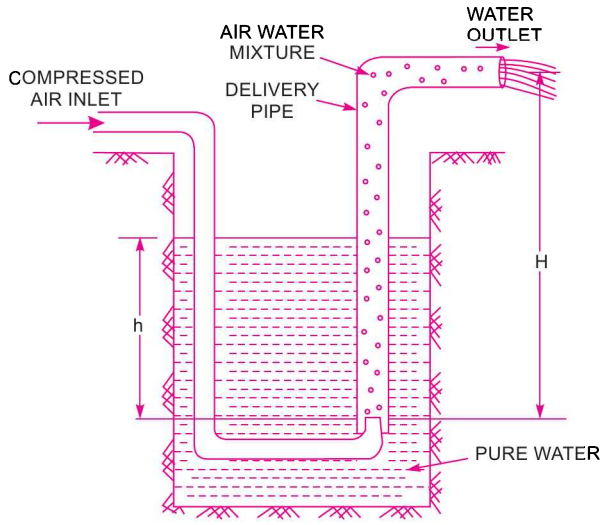

Fig. 21.13 *Air lift pump.*

Fig. 21.13 shows the air lift pump. The compressed air is introduced through one or more nozzles at the foot of the delivery pipe, which is fixed in the well from which water is to be lifted. In the delivery pipe, a mixture of air and water is formed. The density of this air water mixture becomes very less as compared to the density of pure water. Hence, a small column of pure water will balance a very long column of air water mixture. This air water mixture will be discharged out of the delivery pipe. The flow will continue as long as there is supply of compressed air.

Let h = Height of static water level above the tip of the nozzle,

H = Height to which water is lifted above the tip of the nozzle.

The $(H - h)$ is known as the useful lift. The best results are obtained if the useful lift $(H - h)$ is less than the height of static water (h) above the tip of the nozzle. Hence for best results, $(H - h)$ should be less than h.

The ratio $\left(\frac{h}{H-h}\right)$ generally varies from 4 to 1.

When $h = 30$ m, the ratio $\left(\frac{h}{H-h}\right)$ is about 4.

When $h = 90$ m, the ratio $\left(\frac{h}{H-h}\right)$ is 1.

For $h = 30$ m, $\frac{h}{(H-h)} = 4$ or $\frac{30}{(H-30)} = 4$ or $30 = 4H - 120$

or $30 + 120 = 4H$ or $H = \frac{150}{4} = 37.5$ m.

The air lift pump is not having any moving parts below water level and hence there are no chances of suspended solid particles damaging the pump. This is the main advantage of this pump. Also this pump can raise more water through a bore hole of given diameter than any other pump. But the efficiency of this pump is low as out of the energy expended in compressing the air, only 20 to 40% energy appears in the form of useful water horse-power.

▶ 21.11 THE GEAR-WHEEL PUMP

The gear pump is a rotary pump in which two gears mesh to provide the pumping action. This type of pump is mostly used for cooling water and pressure oil to be supplied for lubrication to motors, turbines, machine tools etc. Although the gear pump is a rotating machinery, yet its action on liquid to be pumped is not dynamic and it merely displaces the liquid from one side to the other. The flow of liquid to be pumped is continuous and uniform.

Fig. 21.14 shows the gear pump, which consists of two identical intermeshing gears working in a fine clearance inside a casing. One of the gear is keyed to a driving shaft. The other gear revolves due to driving gear. The space between teeth and the casing is filled with oil. The oil is carried round between the gears from the suction pipe to the delivery pipe.

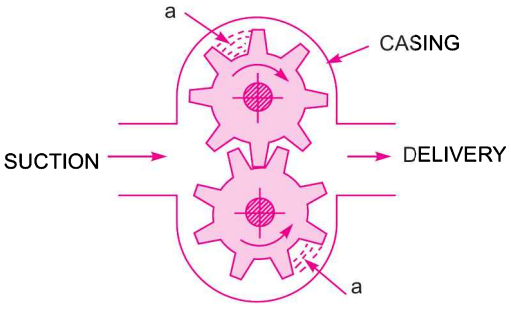

Fig. 21.14 *Gear-wheel pump.*

The mechanical contact between the gears does not allow the flow from inlet to outlet directly. The outer radial tips of the gears and sides of the gears form a part off moving oil.

The oil pushed into the delivery pipe, cannot back into the suction pipe due to the meshing of the gears. The theoretical oil pumped per second is obtained as :

Let N = Speed of rotating gear in r.p.m.,
a = Area enclosed between two successive teeth and casing,
n = Total number of teeth in each gear,
L = Axial length of teeth.

Volume of oil discharged per revolution = $2 \times a \times L \times N$ m^3

$\therefore$ Discharge/s = Volume of oil per revolution $\times$ No. of revolution in one second

$$= 2aLn \times \frac{N}{60} \text{ m}^3$$

The actual discharge will be less than the theoretical discharge.

Now, volumetric efficiency $= \dfrac{\text{Actual discharge}}{\text{Theoretical discharge}}$.

HIGHLIGHTS

1. The devices, based on the principles of fluid statics and fluid kinematics for the transmission of power with the help of a fluid (oil or air), are called fluid or hydraulic devices.
2. A device, which is used for lifting heavy weights by the application of a much smaller force is known as hydraulic press.
3. The device, used for storing the energy of a liquid in the form of pressure energy which may be supplied for any sudden or intermittent requirement, is known as hydraulic accumulator.
4. Capacity of the hydraulic accumulator is given as
$$= p \times A \times L$$
where p = Liquid pressure supplied by pump, A = Area of the sliding ram, L = Stroke or lift of the ram.
5. Differential hydraulic accumulator is a device in which liquid is stored at a high pressure by comparatively small load on the ram.
6. Hydraulic intensifier is a device, in which the pressure intensity of a liquid is increased by means of hydraulic energy available from a large amount of liquid at a low pressure. The increased pressure intensity (p^*) is given by the relation,
$$p^* = \frac{p \times A}{a}$$
where p = Low pressure intensity of liquid, A = External area of the sliding ram,
a = Area of the end of the fixed ram.
7. Hydraulic ram is a pump which raises water without any external power (electricity etc.) for its operation. There are two efficiencies of a hydraulic ram namely D' Aubuisson's efficiency and Rankine efficiency.
They are given by the relations, D' Aubuisson's $\eta = \dfrac{wh}{Wh}$ or $\dfrac{qH}{Qh}$

Rankine's $\eta = \dfrac{w \times (H-h)}{(W-w) \times h}$ or $\dfrac{q \times (H-h)}{(Q-q) \times h}$

where w = Weight of water raised per sec, W = Weight of water flowing per sec into chamber,

h = Height of water above chamber in supply tank, H = Height of water raised above chamber.

8. Hydraulic lift is a device used for carrying persons or goods from one floor to another floor in a multi-storeyed building. They are of two types namely direct acting hydraulic lifts and suspended hydraulic lifts.
9. Hydraulic crane is a device used for raising or transferring heavy weights.
10. Fluid coupling is a device, in which power is transmitted from driving shaft to driven shaft without any change of torque while torque converter is a device in which arrangement is provided for getting increased or decreased torque at the driven shaft.

EXERCISE

(A) THEORETICAL PROBLEMS

1. Explain the term,'Hydraulic devices'. Name any five hydraulic devices.
2. Draw a neat sketch and explain the principle and working of a hydraulic press.
3. Define the term, the hydraulic accumulator. Obtain an expression for the capacity of a hydraulic accumulator. Differentiate between hydraulic accumulator and differential accumulator.
4. What is a hydraulic intensifier ? Explain its principle and working.
5. Differentiate between a hydraulic ram and a centrifugal pump. Obtain an expression for the efficiencies of the hydraulic ram.
6. Explain with the help of a neat sketch, the principle and working of the following hydraulic devices :
   (*a*) Hydraulic lift, (*b*) Hydraulic crane,
   (*c*) Hydraulic coupling, and (*d*) Hydraulic torque converter.
7. What is a difference between a fluid coupling and fluid torque converter? Explain the torque converter with a sketch.
8. Explain with neat sketch, the working of air lift pump. Mention its advantages.
9. How does a torque converter differ from a fluid coupling ? Explain the working principle of any one of them.

(B) NUMERICAL PROBLEMS

1. A hydraulic press has a ram of 300 mm diameter and a plunger of 50 mm diameter. Find the weight lifted by the hydraulic press when the force applied at the plunger is 40 N. [**Ans.** 1440 N]
2. A hydraulic press has a ram of 150 mm diameter and plunger of 30 mm. The stroke of the plunger is 250 mm and weight lifted is 600 N. If the distance moved by the weight is 1.20 m in 20 minutes, determine : (*a*) the force applied on the plunger, (*b*) power required to drive the plunger, and (*c*) number of strokes performed by the plunger. [**Ans.** (*a*) 24 N, (*b*) 0.0006 kW, (*c*) 120]
3. The water is supplied at a pressure of 15 N/cm^2 to an accumulator, having a ram of diameter 2.0 m. If the total lift of the ram is 10 m, determine :
   (*a*) the capacity of the accumulator, and
   (*b*) total weight placed on the ram (including the weight of the ram).
   [**Ans.** (*a*) 4712.4 kNm, (*b*) 471240 N]

4. The diameters of the fixed ram and fixed cylinder of an intensifier are 100 mm and 250 mm respectively. If the pressure of the water supplied to the fixed cylinder is 25 N/cm^2, find the pressure of the water flowing through the fixed ram. [**Ans.** 156.25 N/cm^2]

5. The water is supplied at the rate of 30 litres per second from a height of 4 m to a hydraulic ram, which raises 3 litres per second to a height of 18 m from the ram. Determine D' Aubuisson's and Rankine's efficiencies of the hydraulic ram. [**Ans**. 45%, 38.8%]

6. A hydraulic lift is required to lift a load of 98.1 kN through a height of 12 m, once in every 100 seconds. The speed of the lift is 600 mm/s. Determine :

(*a*) power required to drive the lift, (*b*) working period of lift in seconds, and (*c*) idle period of the lift in seconds. [**Ans.** (*a*) 11.772 kW, (*b*) 20 sec, (*c*) 80 sec]

7. Find the efficiency of a hydraulic crane, which is supplied 400 litres of water under a pressure of 490.5 N/cm^2 for lifting a weight of 98.1 kN through a height of 10 m. [**Ans**. 50%]

8. In a hydraulic coupling, the speeds of the driving and driven shafts are 800 r.p.m. and 780 r.p.m. respectively. Find :

(*a*) the efficiency of the hydraulic coupling, and (*b*) the slip of the coupling. [**Ans.** (*a*) 97.5%, (*b*) 2.5%]

OBJECTIVE TYPE QUESTIONS

Tick mark (√) the most appropriate statement of the multiple choice answers :

1. An ideal fluid is defined as the fluid which
- (*a*) is compressible
- (*b*) is incompressible
- (*c*) is incompressible and non-viscous (inviscid)
- (*d*) has negligible surface tension.

2. Newton's law of viscosity states that
- (*a*) shear stress is directly proportional to the velocity
- (*b*) shear stress is directly proportional to velocity gradient
- (*c*) shear stress is directly proportional to shear strain
- (*d*) shear stress is directly proportional to the viscosity.

3. A Newtonian fluid is defined as the fluid which
- (*a*) is incompressible and non-viscous
- (*b*) obeys Newton's law of viscosity
- (*c*) is highly viscous
- (*d*) is compressible and non-viscous.

4. Kinematic viscosity is defined as equal to
- (*a*) dynamic viscosity × density
- (*b*) dynamic viscosity/density
- (*c*) dynamic viscosity × pressure
- (*d*) pressure × density.

5. Dynamic viscosity (μ) has the dimensions as
- (*a*) MLT^{-2} (*b*) $ML^{-1}T^{-1}$
- (*c*) $ML^{-1}T^{-2}$ (*d*) $M^{-1}L^{-1}T^{-1}$

6. Poise is the unit of
- (*a*) mass density
- (*b*) kinematic viscosity
- (*c*) viscosity
- (*d*) velocity gradient.

7. The increase of temperature
- (*a*) increases the viscosity of a liquid
- (*b*) decreases the viscosity of a liquid
- (*c*) decreases the viscosity of a gas
- (*d*) increases the viscosity of a gas.

8. Stoke is the unit of
- (*a*) surface tension
- (*b*) viscosity
- (*c*) kinematic viscosity
- (*d*) none of the above.

9. The dividing factor for converting one poise into MKS unit of dynamic viscosity is
- (*a*) 9.81 (*b*) 98.1
- (*c*) 981 (*d*) 0.981.

10. Surface tension has the units of
- (*a*) force per unit area
- (*b*) force per unit length
- (*c*) force per unit volume
- (*d*) none of the above.

11. The gases are considered incompressible when Mach number
- (*a*) is equal to 1.0 (*b*) is equal to 0.50
- (*c*) is more than 0.3 (*d*) is less than 0.2.

12. Pascal's law states that pressure at a point is equal in all directions
- (*a*) in a liquid at rest
- (*b*) in a fluid at rest
- (*c*) in a laminar flow
- (*d*) in a turbulent flow.

13. The hydrostatic law states that rate of increase of pressure in a vertical direction is equal to
- (*a*) density of the fluid
- (*b*) specific weight of the fluid
- (*c*) weight of the fluid
- (*d*) none of the above.

14. Fluid statics deals with
- (*a*) viscous and pressure forces
- (*b*) viscous and gravity forces
- (*c*) gravity and pressure forces
- (*d*) surface tension and gravity forces.

15. Gauge pressure at a point is equal to
- (*a*) absolute pressure plus atmospheric pressure
- (*b*) absolute pressure minus atmospheric pressure
- (*c*) vacuum pressure plus absolute pressure
- (*d*) none of the above.

16. Atmospheric pressure held in terms of water column is
- (*a*) 7.5 m (*b*) 8.5 m
- (*c*) 9.81 m (*d*) 10.30 m.

17. The hydrostatic pressure on a plane surface is equal to
- (*a*) $wA\bar{h}$ (*b*) $wA\bar{h}\sin^2\theta$.
- (*c*) $\frac{1}{2}wA\bar{h}$ (*d*) $wA\bar{h}\sin\theta$.

where A = Area of plane surface, and
h = Depth of centroid of the plane area below the liquid-free surface.

18. Centre of pressure of a plane surface immersed in a liquid is
(*a*) above the centre of gravity of the plane surface
(*b*) at the centre of gravity of the plane surface
(*c*) below the centre of gravity of the plane surface
(*d*) none of the above.

19. The resultant hydrostatic force acts through a point known as
(*a*) centre of gravity
(*b*) centre of buoyancy
(*c*) centre of pressure
(*d*) none of the above.

20. For a submerged curved surface, the vertical component of the hydrostatic force is
(*a*) mass of the liquid supported by the curved surface
(*b*) weight of the liquid supported by the curved surface
(*c*) the force on the projected area of the curved surface on vertical plane
(*d*) none of the above.

21. For a floating body, the buoyant force passes through the
(*a*) centre of gravity of the body
(*b*) centre of gravity of the submerged part of the body
(*c*) metacentre of the body
(*d*) centroid of the liquid displaced by the body.

22. The condition of stable equilibrium for a floating body is
(*a*) the metacentre M coincides with the centre of gravity G
(*b*) the metacentre M is below centre of gravity G
(*c*) the metacentre M is above centre of gravity G
(*d*) the centre of buoyancy B is above centre of gravity G.

23. A submerged body will be in stable equilibrium if
(*a*) the centre of buoyancy B is below the centre of gravity G
(*b*) the centre of buoyancy B coincides with G
(*c*) the centre of buoyancy B is above the metacentre M
(*d*) the centre of buoyancy B is above G.

24. The metacentric height of a floating body is
(*a*) the distance between metacentre and centre of buoyancy
(*b*) the distance between the centre of buoyancy and centre of gravity
(*c*) the distance between metacentre and centre of gravity
(*d*) none of the above.

25. The necessary condition for the flow to be steady is that
(*a*) the velocity does not change from place to place
(*b*) the velocity is constant at a point with respect to time
(*c*) the velocity changes at a point with respect to time
(*d*) none of the above.

26. The necessary condition for the flow to be uniform is that
(*a*) the velocity is constant at a point with respect to time
(*b*) the velocity is constant in the flow field with respect to space
(*c*) the velocity changes at a point with respect to time
(*d*) none of the above.

27. The flow in pipe is laminar if
(*a*) Reynolds number is equal to 2500
(*b*) Reynolds number is equal to 4000
(*c*) Reynolds number is more than 2500
(*d*) none of the above.

28. A stream line is a line
(*a*) which is along the path of a particle
(*b*) which is always parallel to the main direction of flow
(*c*) across which there is no flow
(*d*) on which tangent drawn at any point gives the direction of velocity.

29. Continuity equation can take the form
(*a*) $A_1 V_1 = A_2 V_2$
(*b*) $\rho_1 A_1 = \rho_2 A_2$
(*c*) $\rho_1 A_1 V_1 = \rho_2 A_2 V_2$
(*d*) $p_1 A_1 V_1 = p_2 A_2 V_2$.

30. Pitot-tube is used for measurement of
(*a*) pressure
(*b*) flow
(*c*) velocity at a point
(*d*) discharge.

31. Bernoulli's theorem deals with the law of conservation of
(*a*) mass (*b*) momentum
(*c*) energy (*d*) none of the above.

32. Continuity equation deals with the law of conservation of
(*a*) mass (*b*) momentum
(*c*) energy (*d*) none of the above.

33. Irrotational flow means
(*a*) the fluid does not rotated while moving
(*b*) the fluid moves in straight lines
(*c*) the net rotation of fluid particles about their mass centre is zero
(*d*) none of the above.

34. The velocity components in x and y directions in terms of velocity potential (ϕ) are
(*a*) $u = -\frac{\partial \phi}{\partial x}, v = \frac{\partial \phi}{\partial y}$
(*b*) $u = \frac{\partial \phi}{\partial y}, v = \frac{\partial \phi}{\partial x}$
(*c*) $u = -\frac{\partial \phi}{\partial x}, v = -\frac{\partial \phi}{\partial y}$
(*d*) $u = -\frac{\partial \phi}{\partial x}, v = -\frac{\partial \phi}{\partial y}$.

35. The velocity components in x and y directions in terms of stream function (ψ) are
(*a*) $u = \frac{\partial \psi}{\partial x}, v = \frac{\partial \psi}{\partial y}$
(*b*) $u = -\frac{\partial \psi}{\partial x}, v = \frac{\partial \psi}{\partial y}$
(*c*) $u = \frac{\partial \psi}{\partial y}, v = \frac{\partial \psi}{\partial x}$
(*d*) $u = -\frac{\partial \psi}{\partial y}, v = \frac{\partial \psi}{\partial x}$.

36. The relation between tangential velocity (V) and radius (r) is given by
(*a*) $V \times r$ = Constant for forced vortex
(*b*) V/r = Constant for forced vortex
(*c*) $V \times r$ = Constant for free vortex
(*d*) V/r = Constant for free vortex.

37. The pressure variation along the radial direction for vortex flow along a horizontal plane is given as
(*a*) $\frac{\partial p}{\partial r} = -\rho \frac{V^2}{r}$ (*b*) $\frac{\partial p}{\partial r} = \rho \frac{V}{r^2}$
(*c*) $\frac{\partial p}{\partial r} = \rho \frac{V^2}{r}$ (*d*) none of the above.

38. For a forced vortex flow, the height of paraboloid formed is equal to
(*a*) $\frac{p}{\rho g} + \frac{V^2}{2g}$ (*b*) $\frac{V^2}{2g}$
(*c*) $\frac{V^2}{r^2 \times 2g}$ (*d*) $\frac{\omega r^2}{2g}$.

39. Bernoulli's equation is derived making assumptions that
(*a*) the flow is uniform and incompressible
(*b*) the flow is non-viscous, uniform and steady
(*c*) the flow is steady, non-viscous, incompressible and irrotational
(*d*) none of the above.

40. The Bernoulli's equation can take the form
(*a*) $\frac{p_1}{\rho_1} + \frac{V_1^2}{2g} + Z_1 = \frac{p_2}{\rho_2} + \frac{V_2^2}{2g} + Z_2$
(*b*) $\frac{p_1}{\rho_1 g} + \frac{V_1^2}{2} + Z_1 = \frac{p_2}{\rho_2 g} + \frac{V_2^2}{2} + Z_2$
(*c*) $\frac{p_1}{\rho_1 g} + \frac{V_1^2}{2g} + gZ_1 = \frac{p_2}{\rho_2 g} + \frac{V_2^2}{2g} + gZ_2$
(*d*) $\frac{p_1}{\rho_1 g} + \frac{V_1^2}{2g} + Z_1 = \frac{p_2}{\rho_2 g} + \frac{V_2^2}{2g} + Z_2$.

41. The flow rate through a circular pipe is measured by
(*a*) Pitot-tube (*b*) Venturimeter
(*c*) Orifice-meter (*d*) None of the above.

42. The range for co-efficient of discharge (C_d) for a venturimeter is
(*a*) 0.6 to 0.7 (*b*) 0.7 to 0.8
(*c*) 0.8 to 0.9 (*d*) 0.95 to 0.99.

43. The co-efficient of velocity (C_v) for an orifice is
(*a*) $C_v = \sqrt{\frac{4x^2}{yH}}$ (*b*) $C_v = \frac{2x}{\sqrt{4yH}}$
(*c*) $C_v = \sqrt{\frac{x^2}{4yH}}$ (*d*) none of the above.

44. The co-efficient of discharge (C_d) in terms of C_v and C_c is
(*a*) $C_d = \frac{C_v}{C_c}$ (*b*) $C_d = C_v \times C_c$
(*c*) $C_d = \frac{C_c}{C_v}$ (*d*) none of the above.

45. An orifice is known as large orifice when the head of liquid from the centre of orifice is

(*a*) more than 10 times the depth of orifice
(*b*) less than 10 times the depth of orifice
(*c*) less than 5 times the depth of orifice
(*d*) none of the above.

46. Which mouthpiece is having maximum co-efficient of discharge
(*a*) external mouthpiece
(*b*) convergent-divergent mouthpiece
(*c*) internal mouthpiece
(*d*) none of the above.

47. The co-efficient of discharge (C_d)
(*a*) for an orifice is more than that for a mouthpiece
(*b*) for internal mouthpiece is more than that for external mouthpiece
(*c*) for a mouthpiece is more than that for an orifice
(*d*) none of the above.

48. A flow is said to be laminar when
(*a*) the fluid particles moves in a zig-zag way
(*b*) the Reynolds number is high
(*c*) the fluid particles move in layers parallel to the boundary
(*d*) none of the above.

49. For the laminar flow through a circular pipe
(*a*) the maximum velocity = 1.5 times the average velocity
(*b*) the maximum velocity = 2.0 times the average velocity
(*c*) the maximum velocity = 2.5 times the average velocity
(*d*) none of the above.

50. The loss of pressure head for the laminar flow through pipes varies
(*a*) as the square of velocity
(*b*) directly as the velocity
(*c*) as the inverse of the velocity
(*d*) none of the above.

51. For the laminar flow through a pipe, the shear stress over the cross-section
(*a*) varies inversely as the distance from the centre of the pipe
(*b*) varies directly as the distance from the surface of the pipe
(*c*) varies directly as the distance from the centre of the pipe
(*d*) remains constant over the cross-section.

52. For the laminar flow between two parallel plates
(*a*) the maximum velocity = 2.0 times the average velocity
(*b*) the maximum velocity = 2.5 times the average velocity
(*c*) the maximum velocity = 1.33 times the average velocity
(*d*) none of the above.

53. The value of the kinetic energy correction factor (α) of the viscous flow through a circular pipe is
(*a*) 1.33 (*b*) 1.50
(*c*) 2.0 (*d*) 1.25.

54. The value of the momentum correction factor (β) for the viscous flow through a circular pipe is
(*a*) 1.33 (*b*) 1.50
(*c*) 2.0 (*d*) 1.25.

55. The pressure drop per unit length of a pipe for laminar flow is
(*a*) equal to $\frac{12\mu\bar{U}L}{\rho g D^2}$ (*b*) equal to $\frac{12\mu\bar{U}}{\rho g D^2}$
(*c*) equal to $\frac{32\mu\bar{U}L}{\rho g D^2}$ (*d*) none of the above.

56. For viscous flow between two parallel plates, the pressure drop per unit length is equal to
(*a*) $\frac{12\mu\bar{U}L}{\rho g D^2}$ (*b*) $\frac{12\mu\bar{U}L}{D^2}$
(*c*) $\frac{32\mu\bar{U}L}{D^2}$ (*d*) $\frac{12\mu\bar{U}}{D^2}$.

57. The velocity distribution in laminar flow through a circular pipe follow the
(*a*) parabolic law (*b*) linear law
(*c*) logarithmic law (*d*) none of the above.

58. A boundary is known as hydrodynamically smooth if
(*a*) $\frac{k}{\delta'} = 0.3$ (*b*) $\frac{k}{\delta'} > 0.3$
(*c*) $\frac{k}{\delta'} < 0.25$ (*d*) $\frac{k}{\delta'} = 6.0$
where k = Average height of the irregularities from the boundary
and δ' = Thickness of laminar sub-layer.

59. The co-efficient of friction for laminar flow through a circular pipe is given by
(*a*) $f = \frac{0.0791}{(R_e)^{1/4}}$ (*b*) $f = \frac{16}{R_e}$
(*c*) $f = \frac{64}{R_e}$ (*d*) none of the above.

60. The loss of head due to sudden expansion of a pipe is given by

(*a*) $h_L = \frac{V_1^2 - V_2^2}{2g}$ (*b*) $h_L = \frac{0.5\, V_1^2}{2g}$

(*c*) $h_L = \frac{(V_1 - V_2)^2}{2g}$ (*d*) none of the above.

61. The loss of head due to sudden contraction of a pipe is equal to

(*a*) $\left(\frac{1}{C_c} - 1\right)^2 \frac{V_2}{2g}$ (*b*) $\left(1 - \frac{1}{C_c}\right)^2 \frac{V_2}{2g}$

(*c*) $\frac{1}{C_c}\left(1 - \frac{V_2^2}{2g}\right)$ (*d*) none of the above.

62. Hydraulic gradient line (H.G.L.) represents the sum of
(*a*) pressure head and kinetic head
(*b*) kinetic head and datum head
(*c*) pressure head, kinetic head and datum head
(*d*) pressure head and datum head.

63. Total energy line (T.E.L.) represents the sum of
(*a*) pressure head and kinetic head
(*b*) kinetic head and datum head
(*c*) pressure head and datum head
(*d*) pressure head, kinetic head and datum head.

64. When the pipes are connected in series, the total rate of flow
(*a*) is equal to the sum of the rate of flow in each pipe
(*b*) is equal to the reciprocal of the sum of the rate of flow in each pipe
(*c*) is the same as flowing through each pipe
(*d*) none of the above.

65. Power transmitted through pipes, will be maximum when
(*a*) head lost due to friction = $\frac{1}{2}$ total head at inlet of the pipe
(*b*) head lost due to friction = $\frac{1}{4}$ total head at inlet of the pipe
(*c*) head lost due to friction = total head at the inlet of the pipe
(*d*) head lost due to friction = $\frac{1}{3}$ total head at the inlet of the pipe.

66. The valve closure is said to be gradual if the time required to close the valve

(*a*) $t = \frac{2L}{C}$ (*b*) $t \le \frac{2L}{C}$

(*c*) $t < \frac{4L}{C}$ (*d*) $t > \frac{2L}{C}$

where L = Length of pipe, C = Velocity of pressure wave.

67. The velocity of pressure wave in terms of bulk modulus (K) and density (ρ) is given by

(*a*) $C = \sqrt{\frac{\rho}{K}}$ (*b*) $C = \sqrt{K\rho}$

(*c*) $C = \sqrt{\frac{K}{\rho}}$ (*d*) none of the above.

68. Reynold's number is defined as the
(*a*) ratio of inertia force to gravity force
(*b*) ratio of viscous force to gravity force
(*c*) ratio of viscous force to elastic force
(*d*) ratio of inertia force to viscous force.

69. Froude's number is defined as the ratio of
(*a*) inertia force to viscous force
(*b*) inertia force to gravity force
(*c*) inertia force to elastic force
(*d*) inertia force to pressure force.

70. Mach number is defined as the ratio of
(*a*) inertia force to viscous force
(*b*) viscous force to surface tension force
(*c*) viscous force to elastic force
(*d*) inertia force to elastic force.

71. Euler's number is the ratio of
(*a*) inertia force to pressure force
(*b*) inertia force to elastic force
(*c*) inertia force to gravity force
(*d*) none of the above.

72. Models are known undistorted model if
(*a*) the prototype and model are having different scale ratios
(*b*) the prototype and model are having same scale ratio
(*c*) model and prototype are kinematically similar
(*d*) none of the above.

73. Geometric similarity between model and prototype means
(*a*) the similarity discharge
(*b*) the similarity of linear dimensions
(*c*) the similarity of motion
(*d*) the similarity of forces.

74. Kinematic similarity between model and prototype means
(*a*) the similarity of forces
(*b*) the similarity of shape
(*c*) the similarity of motion
(*d*) the similarity of discharge.

75. Dynamic similarity between model and prototype means
(*a*) the similarity of forces
(*b*) the similarity of motion
(*c*) the similarity of shape
(*d*) none of the above.

76. Reynolds number is expressed as

(*a*) $R_e = \frac{\rho \mu L}{V}$ (*b*) $R_e = \frac{V \mu L}{\rho}$

(*c*) $R_e = \frac{\rho V L}{\mu}$ (*d*) $R_e = \frac{V \times d}{\nu}$.

77. Froude's number (F_e) is given by

(*a*) $F_e = V\sqrt{\frac{L}{g}}$ (*b*) $F_e = V\sqrt{\frac{g}{L}}$

(*c*) $F_e = \frac{V}{\sqrt{Lg}}$ (*d*) none of the above.

78. Mach number (M) is given by

(*a*) $M = \frac{C}{V}$ (*b*) $M = V \times C$

(*c*) $M = \frac{V}{C}$ (*d*) none of the above.

79. Boundary layer on a flat plate is called laminar boundary layer if
(*a*) Reynold number is less than 2000
(*b*) Reynold number is less than 4000
(*c*) Reynold number is less than 5×10^5
(*d*) None of the above.

80. Boundary layer thickness (δ) is the distance from the surface of the solid body in the direction perpendicular to flow, where the velocity of fluid is equal to
(*a*) free-stream velocity
(*b*) 0.9 times the free-stream velocity
(*c*) 0.99 times the free-stream velocity
(*d*) none of the above.

81. Displacement thickness (δ^*) is given by

(*a*) $\delta^* = \int_0^{\delta}\left(1 - \frac{U}{u}\right)dy$

(*b*) $\delta^* = \int_0^{\delta} \frac{u}{U}\left(1 - \frac{u}{U}\right)dy$

(*c*) $\delta^* = \int_0^{\delta} \frac{u}{U}\left(1 - \frac{u^2}{U^2}\right)dy$

(*d*) none of the above.

82. Momentum thickness (θ) is given by

(*a*) $\theta = \int_0^{\delta} \frac{u}{U}\left(1 - \frac{u}{U}\right)dy$

(*b*) $\theta = \int_0^{\delta} \left(1 - \frac{u}{U}\right)dy$

(*c*) $\theta = \int_0^{\delta} \frac{u}{U}\left(1 - \frac{u^2}{U^2}\right)dy$

(*d*) none of the above.

83. Energy thickness (δ^{**}) is equal to

(*a*) $\int_0^{\delta} \frac{u}{U}\left[1 - \frac{u}{U}\right]$

(*b*) $\int_0^{\delta} \frac{u}{U}\left(1 - \frac{u^2}{U^2}\right)dy$

(*c*) $\int_0^{\delta} \frac{u}{U}\left(1 - \frac{u}{U}\right)^2$

(*d*) none of the above.

84. Von-Karman momentum integral equation is given as

(*a*) $\frac{\tau_0}{\frac{1}{2}\rho U^2} = \frac{\partial \theta}{\partial x}$ (*b*) $\frac{\tau_0}{\rho U^2} = \frac{\partial \theta}{\partial x}$

(*c*) $\frac{\tau_0}{2\rho U^2} = \frac{\partial \theta}{\partial x}$ (*d*) none of the above.

85. The boundary layer separation takes place if
(*a*) pressure gradient is zero
(*b*) pressure gradient is positive
(*c*) pressure gradient is negative
(*d*) none of the above.

86. The condition for boundary layer separation is

(*a*) $\left(\frac{\partial u}{\partial y}\right)_{y=0} = +\text{ve}$ (*b*) $\left(\frac{\partial u}{\partial y}\right)_{y=0} = -\text{ve}$

(*c*) $\left(\frac{\partial u}{\partial y}\right)_{y=0} = 0$ (*d*) none of the above.

87. The boundary layer flow will be attached to the surface if

(*a*) $\left(\frac{\partial u}{\partial y}\right)_{y=0} = 0$ (*b*) $\left(\frac{\partial u}{\partial y}\right)_{y=0} = +\text{ve}$

(*c*) $\left(\frac{\partial u}{\partial y}\right)_{y=0}$ = –ve (*d*) none of the above.

88. The condition for detached flow is

(*a*) $\left(\frac{\partial u}{\partial y}\right)_{y=0} = 0$ (*b*) $\left(\frac{\partial u}{\partial y}\right)_{y=0}$ = +ve

(*c*) $\left(\frac{\partial u}{\partial y}\right)_{y=0}$ = –ve (*d*) none of the above.

89. Drag is defined as the force exerted by a flowing fluid on a solid body
(*a*) in the direction of flow
(*b*) perpendicular to the direction of flow
(*c*) in the direction which is at an angle of 45° to the direction of flow
(*d*) none of the above.

90. Lift force is defined as the force exerted by a flowing fluid on a solid body
(*a*) in the direction of flow
(*b*) perpendicular to the direction of flow
(*c*) at an angle of 45° to the direction of flow
(*d*) none of the above.

91. Drag force is expressed mathematically, as

(*a*) $F_D = \frac{1}{2}\rho U^2 \times C_D \times A$

(*b*) $F_D = \rho U^2 \times C_D \times A$

(*c*) $F_D = 2\rho U^2 \times C_D \times A$

(*d*) none of the above.

92. Lift force (F_L) is expressed mathematically, as

(*a*) $F_L = \frac{1}{2}\rho U^2 \times C_L$

(*b*) $F_L = \frac{1}{2}\rho U^2 \times C_L \times A$

(*c*) $F_L = 2\rho U^2 \times C_L \times A$

(*d*) $F_L = \rho U^2 \times C_L \times A$.

93. Total drag on a body is the sum of
(*a*) pressure drag and velocity drag
(*b*) pressure drag and friction drag
(*c*) friction drag and velocity drag
(*d*) none of the above.

94. A body is called stream lined body when it is placed in a flow and the surface of the body
(*a*) coincides with streamlines
(*b*) does not coincide with the streamlines
(*c*) is perpendicular to the streamlines
(*d*) none of the above.

95. A body is called bluff body if the surface of the body
(*a*) coincides with the streamlines
(*b*) does not coincide with the streamlines
(*c*) is very smooth
(*d*) none of the above.

96. The drag on a sphere (F_D) for Reynold's number less than 0.2 is given by
(*a*) $F_D = 5\pi\mu DU$ (*b*) $F_D = 3\pi\mu DU$
(*c*) $F_D = 2\ \pi\mu DU$ (*d*) $F_D = \pi\mu DU$.

97. The skin friction drag on a sphere (for Reynold's number less than 0.2) is equal to
(*a*) one-third of the total drag
(*b*) half of the total drag
(*c*) two-third of the total drag
(*d*) none of the above.

98. The pressure drag on a sphere (for Reynold's number less than 0.2) is equal to
(*a*) one-third of the total drag
(*b*) half of the total drag
(*c*) two-third of the total drag
(*d*) none of the above.

99. Terminal velocity of a falling body is equal to
(*a*) a maximum velocity with which body will fall
(*b*) the maximum constant velocity with which body will fall
(*c*) half of the maximum velocity
(*d*) none of the above.

100. When a falling body has attained terminal velocity, the weight of the body is equal to
(*a*) drag force minus buoyant force
(*b*) buoyant force minus drag force
(*c*) drag force plus the buoyant force
(*d*) none of the above.

101. The tangential velocity of ideal fluid at any point on the surface of the cylinder is given by

(*a*) $u_\theta = \frac{1}{2}\ U \sin\theta$ (*b*) $u_\theta = U \sin\theta$

(*c*) $u_\theta = 2U \sin\theta$ (*d*) none of the above.

102. The lift force (F_L) produced on a rotating circular cylinder in a uniform flow is given by

(*a*) $F_L = \frac{LU\Gamma}{\rho}$ (*b*) $F_L = \rho LU\Gamma$

(*c*) $F_L = \frac{\rho U\Gamma}{\rho}$ (*d*) $F_L = \frac{\rho LU}{\Gamma}$

where L = Length of the cylinder, U = Free-stream velocity, Γ = Circulation.

103. The lift co-efficient (C_L) for a rotating cylinder in a uniform flow is given by

(*a*) $C_L = \dfrac{\Gamma U}{R}$ (*b*) $C_L = \dfrac{\Gamma R}{U}$

(*c*) $C_L = \dfrac{\Gamma}{RU}$ (*d*) $C_L = \dfrac{RU}{\Gamma}$.

104. Kinematic viscosity (ν) is equal to

(*a*) $\mu \times \rho$ (*b*) $\dfrac{\mu}{\rho}$

(*c*) $\dfrac{\rho}{\mu}$ (*d*) none of the above.

105. Compressibility is equal to

(*a*) $\dfrac{\left(\dfrac{dV}{V}\right)}{dp}$ (*b*) $\dfrac{dp}{-\left(\dfrac{dV}{V}\right)}$

(*c*) $\dfrac{dp}{d\rho}$ (*d*) $\sqrt{\dfrac{dp}{d\rho}}$.

106. Hydrostatic law of pressure is given as

(*a*) $\dfrac{\partial p}{\partial z} = \rho g$ (*b*) $\dfrac{\partial p}{\partial z} = 0$

(*c*) $\dfrac{\partial p}{\partial z} = z$ (*d*) $\dfrac{\partial p}{\partial z}$ = constant.

107. Four curves are shown in Fig. 1 with velocity gradient $\left(\dfrac{\partial u}{\partial y}\right)$ along x-axis and viscous shear stress (τ) along y-axis. Curve A corresponds to

(*a*) ideal fluid
(*b*) newtonian fluid
(*c*) non-newtonian fluid
(*d*) ideal solid.

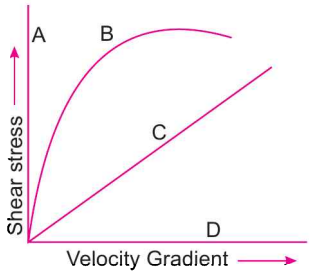

Fig. 1

108. Curve B in Fig.1 corresponds to

(*a*) ideal fluid
(*b*) newtonian fluid
(*c*) non-newtonian fluid
(*d*) ideal solid.

109. Curve C in Fig. 1 corresponds to

(*a*) ideal fluid
(*b*) newtonian fluid
(*c*) non-newtonian fluid
(*d*) ideal solid.

110. Curve D in Fig. 1 corresponds to

(*a*) ideal fluid
(*b*) newtonian fluid
(*c*) non-newtonian fluid
(*d*) ideal solid.

111. The relation between surface tension (σ) and difference of pressure (Δp) between the inside and outside of a liquid droplet is given as

(*a*) $\Delta p = \dfrac{\sigma}{4d}$ (*b*) $\Delta p = \dfrac{\sigma}{2d}$

(*c*) $\Delta p = \dfrac{4\sigma}{d}$ (*d*) $\Delta p = \dfrac{\sigma}{d}$.

112. For a soap bubble, the surface tension (σ) and difference of pressure (Δp) are related as

(*a*) $\Delta p = \dfrac{\sigma}{4d}$ (*b*) $\Delta p = \dfrac{\sigma}{2d}$

(*c*) $\Delta p = \dfrac{4\sigma}{d}$ (*d*) $\Delta p = \dfrac{8\sigma}{d}$.

113. For a liquid jet, the surface tension (σ) and difference of pressure (Δp) are related as

(*a*) $\Delta p = \dfrac{\sigma}{4d}$ (*b*) $\Delta p = \dfrac{\sigma}{2d}$

(*c*) $\Delta p = \dfrac{4\sigma}{d}$ (*d*) $\Delta p = \dfrac{2\sigma}{d}$.

114. The capillary rise or fall of a liquid is given by

(*a*) $h = \dfrac{\sigma \cos\theta}{4\rho g d}$ (*b*) $h = \dfrac{4\sigma \cos\theta}{\rho g d}$

(*c*) $h = \dfrac{8\sigma \cos\theta}{\rho g d}$ (*d*) none of the above.

115. Manometer is a device used for measuring

(*a*) velocity at a point in fluid
(*b*) pressure at a point in a fluid
(*c*) discharge of a fluid
(*d*) none of the above.

116. Differential manometers are used for measuring

(*a*) velocity at a point in a fluid
(*b*) pressure at a point in a fluid
(*c*) difference of pressure between two points
(*d*) none of the above.

117. The pressure at a height Z in a static compressible fluid undergoing isothermal compression is given by

(*a*) $p = p_0 e^{-\frac{gR}{ZT}}$ (*b*) $p = p_0 e^{-\frac{gT}{RZ}}$

(*c*) $p = p_0 e^{-\frac{RT}{gZ}}$ (*d*) $p = p_0 e^{-\frac{gT}{RT}}$

where p_0 = Pressure at ground level, R = Gas constant, T = Absolute temperature.

118. The pressure at a height Z in a static compressible fluid undergoing adiabatic compression is given by

(*a*) $p = p_0\left[1-\frac{\gamma-1}{\gamma}\frac{RT_0}{gZ}\right]^{\frac{\gamma}{\gamma-1}}$

(*b*) $p = p_0\left[1-\frac{\gamma}{\gamma-1}\frac{RT_0}{gZ}\right]^{\frac{\gamma}{\gamma-1}}$

(*c*) $p = p_0\left[1-\frac{\gamma-1}{\gamma}\frac{gZ}{RT_0}\right]^{\frac{\gamma}{\gamma-1}}$

(*d*) none of the above.

119. The temperature at a height Z in a static compressible fluid undergoing adiabatic compression is given as

(*a*) $T = T_0\left[1-\frac{\gamma-1}{\gamma}\frac{RT_0}{gZ}\right]$

(*b*) $T = T_0\left[1-\frac{\gamma-1}{\gamma}\frac{gZ}{RT_0}\right]$

(*c*) $T = T_0\left[1-\frac{\gamma}{\gamma-1}\frac{RT_0}{gZ}\right]$

(*d*) none of the above.

120. Temperature lapse-rate is given by

(*a*) $L = -\frac{R}{g}\left[\frac{\gamma-1}{\gamma}\right]$ (*b*) $L = -\frac{R}{g}\left[\frac{\gamma}{\gamma-1}\right]$

(*c*) $L = -\frac{g}{R}\left[\frac{\gamma-1}{\gamma}\right]$ (*d*) none of the above.

121. When the fluid is at rest, the shear stress is

(*a*) maximum (*b*) zero

(*c*) unpredictable (*d*) none of the above.

122. The depth of centre of pressure of an inclined immersed surface from free surface of liquid is equal to

(*a*) $\frac{I_G}{A\bar{h}}+\bar{h}$ (*b*) $\frac{I_G A\sin^2\theta}{\bar{h}}+\bar{h}$

(*c*) $\frac{I_G\sin^2\theta}{A\bar{h}}+\bar{h}$ (*d*) $\frac{I_G\bar{h}}{A\sin^2\theta}+\bar{h}.$

123. The depth of centre of pressure of a vertical immersed surface from free surface of liquid is equal to

(*a*) $\frac{I_G}{A\bar{h}}+\bar{h}$ (*b*) $\frac{I_G A}{\bar{h}}+\bar{h}$

(*c*) $\frac{I_G\bar{h}}{\bar{h}}+\bar{h}$ (*d*) $\frac{A\bar{h}}{I_G}+\bar{h}.$

124. The centre of pressure for a plane vertical surface lies at a depth of

(*a*) half the height of the immersed surface

(*b*) one-third the height of the immersed surface

(*c*) two-third the height of the immersed surface

(*d*) none of the above.

125. The inlet length of a venturimeter

(*a*) is equal to the outlet length

(*b*) is more than the outlet length

(*c*) is less than the outlet length

(*d*) none of the above.

126. Flow of a fluid in a pipe takes place from

(*a*) higher level to lower level

(*b*) higher pressure to lower pressure

(*c*) higher energy to lower energy

(*d*) none of the above.

127. The point, through which the buoyant force is acting, is called

(*a*) centre of pressure

(*b*) centre of gravity

(*c*) centre of buoyancy

(*d*) none of the above.

128. The point, through which the weight is acting, is called

(*a*) centre of pressure

(*b*) centre of gravity

(*c*) centre of buoyancy

(*d*) none of the above.

129. The point, about which a floating body starts oscillating when the body is tilted, is called

(*a*) centre of pressure

(*b*) centre of buoyancy

(*c*) centre of gravity

(*d*) metacentre.

130. The metacentric height (GM) is given by

(a) $GM = BG - \frac{I}{V}$ (b) $GM = \frac{V}{I} - BG$

(c) $GM = \frac{I}{V} - BG$ (d) none of the above.

131. For a floating body, if the metacentre is above the centre of gravity, the equilibrium is called

(a) stable (b) unstable

(c) neutral (d) none of the above.

132. For a floating body, if the metacentre is below the centre of gravity, the equilibrium is called

(a) stable (b) unstable

(c) neutral (d) none of the above.

133. For a floating body, if the metacentre coincides with the centre of gravity, the equilibrium is called

(a) stable (b) unstable

(c) neutral (d) none of the above.

134. For a floating body, if centre of buoyancy is above the centre of gravity, the equilibrium is called

(a) stable (b) unstable

(c) neutral (d) none of the above.

135. For a sub-merged body, if the centre of buoyancy is above the centre of gravity, the equilibrium is called

(a) stable (b) unstable

(c) neutral (d) none of the above.

136. For a sub-merged body, if the centre of buoyancy is below the centre of gravity, the equilibrium is called

(a) stable (b) unstable

(c) neutral (d) none of the above.

137. For a sub-merged body, if the centre of buoyancy coincides with the centre of gravity, the equilibrium is called

(a) stable (b) unstable

(c) neutral (d) none of the above.

138. For a sub-merged body, if the metacentre is below the centre of gravity, the equilibrium is called

(a) stable (b) unstable

(c) neutral (d) none of the above.

139. The metacentric height (GM) experimentally is given as

(a) $GM = \frac{W \tan\theta}{wx}$ (b) $GM = \frac{w \tan\theta}{W \times x}$

(c) $GM = \frac{wx}{W \tan\theta}$ (d) $GM = \frac{Wx}{w \tan\theta}$

where w = Movable weight, W = Weight of floating body including w, θ = Angle of tilt.

140. The time period of oscillation of a floating body is given by

(a) $T = 2\pi\sqrt{\frac{GM \times g}{k^2}}$ (b) $T = 2\pi\sqrt{\frac{k^2}{GM \times g}}$

(c) $T = 2\pi\sqrt{\frac{GM}{gk^2}}$ (d) $T = 2\pi\sqrt{\frac{gk^2}{GM}}$.

where k = Radius of gyration, GM = Metacentric height, and T = Time period.

141. If the velocity, pressure, density etc., do not change at a point with respect to time, flow is called

(a) uniform (b) incompressible

(c) non-uniform (d) steady.

142. If the velocity, pressure, density, etc., change at a point with respect to time, the flow is called

(a) uniform (b) compressible

(c) unsteady (d) incompressible.

143. If the velocity in a fluid flow does not change with respect to length of direction of flow, it is called

(a) steady flow

(b) uniform flow

(c) incompressible flow

(d) rotational flow.

144. If the velocity in a fluid flow changes with respect to length of direction of flow, it is called

(a) unsteady flow

(b) compressible flow

(c) irrotational flow

(d) none of the above.

145. If the density of a fluid is constant from point to point in a flow region, it is called

(a) steady flow

(b) incompressible flow

(c) uniform flow

(d) rotational flow.

146. If the density of a fluid changes from point to point in a flow region, it is called

(a) steady flow (b) unsteady flow

(c) non-uniform flow (d) compressible flow.

147. If the fluid particles move in straight lines and all the lines are parallel to the surface, the flow is called

(a) steady (b) uniform

(c) compressible (d) laminar.

148. If the fluid particles move in a zig-zag way, the flow is called

(a) unsteady (b) non-uniform

(c) turbulent (d) incompressible.

149. The acceleration of a fluid particle in the direction of x is given by

(*a*) $A_x = u\dfrac{\partial u}{\partial x} + v\dfrac{\partial v}{\partial y} + w\dfrac{\partial w}{\partial z} + \dfrac{\partial u}{\partial t}$

(*b*) $A_x = u\dfrac{\partial u}{\partial x} + u\dfrac{\partial v}{\partial y} + u\dfrac{\partial w}{\partial z} + \dfrac{\partial u}{\partial t}$

(*c*) $A_x = u\dfrac{\partial u}{\partial x} + v\dfrac{\partial u}{\partial y} + w\dfrac{\partial u}{\partial z} + \dfrac{\partial u}{\partial t}$

(*d*) none of the above.

150. The local acceleration in the direction of x is given by

(*a*) $u\dfrac{\partial u}{\partial x} + \dfrac{\partial u}{\partial t}$ (*b*) $\dfrac{\partial u}{\partial t}$

(*c*) $u\dfrac{\partial u}{\partial x}$ (*d*) none of the above.

151. The convective acceleration in the direction of x is given by

(*a*) $u\dfrac{\partial u}{\partial y} + v\dfrac{\partial v}{\partial y} + w\dfrac{\partial w}{\partial z}$

(*b*) $u\dfrac{\partial u}{\partial x} + u\dfrac{\partial u}{\partial y} + u\dfrac{\partial u}{\partial z}$

(*c*) $u\dfrac{\partial u}{\partial x} + u\dfrac{\partial v}{\partial y} + u\dfrac{\partial w}{\partial z}$

(*d*) $u\dfrac{\partial u}{\partial x} + v\dfrac{\partial u}{\partial y} + w\dfrac{\partial u}{\partial z}$.

152. Shear strain rate is given by

(*a*) $\dfrac{1}{2}\left(\dfrac{\partial u}{\partial x} + \dfrac{\partial v}{\partial y}\right)$ (*b*) $\dfrac{1}{2}\dfrac{\partial u}{\partial x} + \dfrac{\partial v}{\partial y}$

(*c*) $\dfrac{1}{2}\left(\dfrac{\partial v}{\partial x} + \dfrac{\partial u}{\partial y}\right)$ (*d*) $\dfrac{1}{2}\dfrac{\partial v}{\partial x} + \dfrac{\partial u}{\partial y}$.

153. For a two-dimensional fluid element in x-y plane, the rotational component is given as

(*a*) $\omega_z = \dfrac{1}{2}\left(\dfrac{\partial v}{\partial x} + \dfrac{\partial u}{\partial y}\right)$

(*b*) $\omega_z = \dfrac{1}{2}\left(\dfrac{\partial u}{\partial x} - \dfrac{\partial v}{\partial y}\right)$

(*c*) $\omega_z = \dfrac{1}{2}\left(\dfrac{\partial u}{\partial x} + \dfrac{\partial v}{\partial y}\right)$

(*d*) $\omega_z = \dfrac{1}{2}\left(\dfrac{\partial v}{\partial x} - \dfrac{\partial u}{\partial y}\right)$.

154. Vorticity is given by

(*a*) two times the rotation
(*b*) 1.5 times the rotation
(*c*) three times the rotation
(*d*) equal to the rotation.

155. Study of fluid motion with the forces causing the flow is known as

(*a*) kinematics of fluid flow
(*b*) dynamics of fluid flow
(*c*) statics of fluid flow
(*d*) none of the above.

156. Study of fluid motion without considering the forces, causing the flow, is known as

(*a*) kinematics of fluid flow
(*b*) dynamics of fluid flow
(*c*) statics of fluid flow
(*d*) none of the above.

157. Study of fluid at rest is known as

(*a*) kinematics (*b*) dynamics
(*c*) statics (*d*) none of the above.

158. The term $V^2/2g$ is known as

(*a*) kinetic energy
(*b*) pressure energy
(*c*) kinetic energy per unit weight
(*d*) none of the above.

159. The terms $p/\rho g$ is known as

(*a*) kinetic energy per unit weight
(*b*) pressure energy
(*c*) pressure energy per unit weight
(*d*) none of the above.

160. The term Z is known as

(*a*) potential energy
(*b*) pressure energy
(*c*) potential energy per unit weight
(*d*) none of the above.

161. The discharge through a venturimeter is given as

(*a*) $Q = \dfrac{A_1^2 A_2^2}{\sqrt{A_1^2 - A_2^2}} \times \sqrt{2gh}$

(*b*) $Q = \dfrac{A_1 A_2}{\sqrt{2A_1^2 - A_2^2}} \times \sqrt{2gh}$

(*c*) $Q = \dfrac{A_1 A_2}{\sqrt{A_1^2 - A_2^2}} \times \sqrt{2gh}$

(*d*) none of the above.

162. The difference of pressure head (h) measured by mercury-oil differential manometer is given as

(*a*) $h = x\left[1 - \frac{S_g}{S_o}\right]$ (*b*) $h = x\left[S_g - S_o\right]$

(*c*) $h = x\left[S_o - S_g\right]$ (*d*) $h = x\left[\frac{S_g}{S_o} - 1\right]$

where x = Difference of mercury level, S_g = Specific gravity of mercury and S_o = Specific gravity of oil.

163. The difference of pressure head (h) measured by a differential manometer containing lighter liquid is

(*a*) $h = x\left[1 - \frac{S_l}{S_o}\right]$ (*b*) $h = x\left[\frac{S_l}{S_o} - 1\right]$

(*c*) $h = x\left[S_o - S_l\right]$ (*d*) none of the above.

where S_l = Specific gravity of lighter liquid in manometer.

S_o = Specific gravity of fluid flowing

x = Difference of lighter liquid levels in differential manometer.

164. Pitot-tube is used to measure
(*a*) discharge
(*b*) average velocity
(*c*) velocity at a point
(*d*) pressure at a point.

165. Venturimeter is used to measure
(*a*) discharge
(*b*) average velocity
(*c*) velocity at a point
(*d*) pressure at a point.

166. Orifice-meter is used to measure
(*a*) discharge
(*b*) average velocity
(*c*) velocity at a point
(*d*) pressure at a point.

167. For a sub-merged curved surface, the horizontal component of force due to static liquid is equal to
(*a*) weight of liquid supported by the curved surface
(*b*) force on a projection of the curved surface on a vertical plane
(*c*) area of curved surface × pressure at the centroid of the submerged area
(*d*) none of the above.

168. For a sub-merged curved surface, the vertical component of force due to static liquid is equal to
(*a*) weight of the liquid supported by curved surface
(*b*) force on a projection of the curved surface on a vertical plane
(*c*) area of curved surface × pressure at the centroid of the sub-merged area
(*d*) none of the above.

169. An oil of specific gravity 0.7 and pressure 0.14 kgf/cm^2 will have the height of oil as
(*a*) 70 cm of oil (*b*) 2 m of oil
(*c*) 20 cm of oil (*d*) 80 cm of oil.

170. The difference in pressure head, measured by a mercury water differential manometer for a 20 cm difference of mercury level will be
(*a*) 2.72 m (*b*) 2.52 m
(*c*) 2.0 m (*d*) 0.2 m.

171. The difference in pressure head, measured by a mercury-oil differential manometer for a 20 cm difference of mercury level will be (sp. gravity of oil = 0.8)
(*a*) 2.72 m of oil (*b*) 2.52 m of oil
(*c*) 3.20 m of oil (*d*) 2.0 m of oil.

172. The rate of flow through a venturimeter varies as
(*a*) H (*b*) $\sqrt{H}$
(*c*) $H^{3/2}$ (*d*) $H^{5/2}$.

173. The rate of flow through a V-notch varies as
(*a*) H (*b*) $\sqrt{H}$
(*c*) $H^{3/2}$ (*d*) $H^{5/2}$.

174. Orifices are used to measure
(*a*) velocity (*b*) pressure
(*c*) rate of flow (*d*) none of the above.

175. Mouthpieces are used to measure
(*a*) velocity (*b*) pressure
(*c*) viscosity (*d*) rate of flow.

176. The ratio of actual velocity of a jet of water at vena-contracta to the theoretical velocity, is known as
(*a*) co-efficient of discharge
(*b*) co-efficient of velocity
(*c*) co-efficient of contraction
(*d*) co-efficient of viscosity.

177. The ratio of actual discharge of a jet of water to its theoretical discharge is known as
(*a*) co-efficient of discharge
(*b*) co-efficient of velocity
(*c*) co-efficient of contraction
(*d*) co-efficient of viscosity.

178. The ratio of the area of the jet of water at vena-contracta to the area of orifice, is known as
(*a*) co-efficient of discharge
(*b*) co-efficient of velocity
(*c*) co-efficient of contraction
(*d*) co-efficient of viscosity.

179. The discharge through a large rectangular orifice is
(*a*) $\frac{2}{3}C_d \times b \times \sqrt{2g}(\sqrt{H_2} - \sqrt{H_1})$
(*b*) $\frac{8}{15}C_d \times b \times \sqrt{2g}(H_2^{3/2} - H_1^{3/2})$
(*c*) $\frac{2}{3}C_d \times b \times \sqrt{2g}(H_2^{3/2} - H_1^{3/2})$
(*d*) none of the above.
where b = Width of orifice, H_1 = Height of liquid above top edge of the orifice,
H_2 = Height of liquid above bottom edge of orifice.

180. The discharge through fully sub-merged orifice is
(*a*) $C_d \times b \times (H_2 - H_1) \times \sqrt{2g} \times H^{3/2}$
(*b*) $C_d \times b \times (H_2 - H_1) \times \sqrt{2gH}$
(*c*) $C_d \times b \times (H_2^{3/2} - H_1^{3/2}) \times \sqrt{2gH}$
(*d*) none of the above
where H = Difference of liquid level on both sides of the orifice,
H_1 = Height of liquid above top edge orifice on upstream side,
H_2 = Height of liquid above bottom edge of orifice on upstream side.

181. Notch is a device used for measuring
(*a*) rate of flow through pipes
(*b*) rate of flow through a small channel
(*c*) velocity through a pipe
(*d*) velocity through a small channel.

182. The discharge through a rectangular notch is given by
(*a*) $Q = \frac{2}{3}C_d \times L \times H^{5/2}$
(*b*) $Q = \frac{2}{3}C_d \times L \times H^{3/2}$
(*c*) $Q = \frac{8}{15}C_d \times L \times H^{5/2}$
(*d*) $\frac{8}{15}Q = \frac{8}{15}C_d \times L \times H^{3/2}$.

183. The discharge through a triangular notch is given by
(*a*) $Q = \frac{2}{3}C_d \times \tan\frac{\theta}{2} \times \sqrt{2gH}$
(*b*) $Q = \frac{2}{3}C_d \times \tan\frac{\theta}{2} \times \sqrt{2g} \times H^{3/2}$
(*c*) $Q = \frac{2}{15}C_d \times \tan\frac{\theta}{2} \times \sqrt{2g}\ H^{5/2}$
(*d*) none of the above.
where θ = Total angle of triangular notch,
H = Head over notch.

184. The discharge through a trapezoidal notch is given as
(*a*) $Q = \frac{2}{3}C_{d_1} \times L \times H^{3/2} + \frac{8}{15} \times C_{d_2} \times \tan\theta/2 \times \sqrt{2g} \times H^{3/2}$
(*b*) $Q = \frac{2}{3}C_{d_1} \times L \times H^{5/2} + \frac{8}{15} \times C_{d_2} \times \tan\theta/2 \times \sqrt{2g}H^{3/2}$
(*c*) $Q = \frac{2}{3}C_{d_1} \times L \times H^{3/2} + \frac{8}{15} \times C_{d_2} \times \tan\theta/2 \times \sqrt{2g}H^{5/2}$
(*d*) none of the above
where $\theta/2$ = Slope of the side of the trapezoidal notch.

185. The error in discharge due to the error in the measurement of head over a rectangular notch is given by
(*a*) $\frac{dQ}{Q} = \frac{5}{2}\frac{dH}{H}$ (*b*) $\frac{dQ}{Q} = \frac{3}{2}\frac{dH}{H}$
(*c*) $\frac{dQ}{Q} = \frac{7}{2}\frac{dH}{H}$ (*d*) $\frac{dQ}{Q} = \frac{1}{2}\frac{dH}{H}$.

186. The error in discharge due to the error in the measurement of head over a triangular notch is given by
(*a*) $\frac{dQ}{Q} = \frac{5}{2}\frac{dH}{H}$ (*b*) $\frac{dQ}{Q} = \frac{3}{2}\frac{dH}{H}$
(*c*) $\frac{dQ}{Q} = \frac{7}{2}\frac{dH}{H}$ (*d*) $\frac{dQ}{Q} = \frac{1}{2}\frac{dH}{H}$.

187. The velocity with which the water approaches a notch is called
(*a*) velocity of flow
(*b*) velocity of approach
(*c*) velocity of whirl
(*d*) none of the above.

188. The discharge over a rectangular notch considering velocity of approach is given as
(*a*) $Q = \frac{2}{3} C_d L \sqrt{2g}\,(H^{3/2} - h_a^{3/2})$
(*b*) $Q = \frac{2}{3} C_d L \sqrt{2g}\,(H - h_a)^{3/2}$
(*c*) $Q = \frac{2}{3} C_d L \sqrt{2g}\,[(H + h_a)^{3/2} - h_a^{3/2}]$
(*d*) none of the above.
where H = Head over notch, and h_a = Head due to velocity of approach.

189. The velocity of approach (V_a) is given by
(*a*) $V_a = \frac{\text{Discharge over notch}}{\text{Area of notch}}$
(*b*) $V_a = \frac{\text{Discharge over notch}}{\text{Area of channel}}$
(*c*) $V_a = \frac{\text{Discharge over notch}}{\text{Head over notch} \times \text{Width of channel}}$
(*d*) none of the above.

190. Francis's formula for a rectangular weir with end contraction suppressed is given as
(*a*) $Q = 1.84\, L\, H^{5/2}$ (*b*) $Q = \frac{2}{3} L \times H^{3/2}$
(*c*) $Q = 1.84\, L\, H^{3/2}$ (*d*) $Q = \frac{2}{3} L \times H^{5/2}$.

191. Francis's formula for a rectangular weir for two end contractions is given by
(*a*) $Q = 1.84[L - 0.2H]H^{5/2}$
(*b*) $Q = 1.84[L - 0.2H]H^{3/2}$
(*c*) $Q = 1.84[L - 0.2H]H^{5/2}$
(*d*) none of the above.

192. Bazin's formula for discharge over a rectangular weir without velocity of approach is given by
(*a*) $Q = mL \times \sqrt{2g}\, H^{5/2}$
(*b*) $Q = mL \times \sqrt{2g} \times H^{3/2}$
(*c*) $Q = m \times L \times \sqrt{2gH}$
(*d*) none of the above.
where $m = 0.405 + \frac{0.003}{H}$ and H = Head over weir.

193. Cipolletti weir is a trapezoidal weir having side slope of
(*a*) 1 horizontal to 2 vertical
(*b*) 4 horizontal to 1 vertical
(*c*) 1 horizontal to 4 vertical
(*d*) 1 horizontal to 3 vertical.

194. The co-efficient of friction in terms of shear stress is given by
(*a*) $f = \frac{2\rho V^2}{\tau_0}$ (*b*) $f = \frac{2\tau_0}{\rho V^2}$
(*c*) $f = \frac{\tau_0}{2\rho V^2}$ (*d*) $f = \frac{\rho V^2}{2\tau_0}$

195. When the pipes are connected in parallel, the total loss of head
(*a*) is equal to the sum of the loss of head in each pipe
(*b*) is same as in each pipe
(*c*) is equal to the reciprocal of the sum of loss of head in each pipe
(*d*) none of the above.

196. L_1, L_2, L_3 and the length of three pipes, connected in series. If d_1, d_2 and d_3 are their diameters, then the equivalent size of the pipe is given by
(*a*) $\frac{L}{d^5} = \frac{L_1}{d_1^5} + \frac{L_2}{d_2^5} + \frac{L_3}{d_3^5}$
(*b*) $\frac{d^5}{L} = \frac{d_1^5}{L_1} + \frac{d_2^5}{L_2} + \frac{d_3^5}{L_3}$
(*c*) $Ld^5 = L_1 d_2^5 + L_2 d_2^5 + L_3 d_3^5$
(*d*) none of the above.

197. The power transmitted through pipe is given by
(*a*) $\frac{\rho g \times Q \times H}{1000}$
(*b*) $\frac{\rho g \times Q \times h_f}{1000}$
(*c*) $\frac{\rho g \times Q \times (H - h_f)}{4500}$
(*d*) $\frac{\rho g \times Q \times (H - h_f)}{1000}$
where H = Total head at the inlet of pipe, h_f = Head lost due to friction in pipe and Q = discharge per second.

198. Efficiency of power transmission through pipe is given by

(*a*) $\frac{H - h_f}{H}$ (*b*) $\frac{H}{H + h_f}$

(*c*) $\frac{H - h_f}{H + h_f}$ (*d*) none of the above

where H = Total head at inlet, h_f = Head lost due to friction.

199. Maximum efficiency of power transmission through pipe is

(*a*) 50% (*b*) 66.67%

(*c*) 75% (*d*) 100%.

200. For a viscous flow through circular pipes, certain curves are shown in Fig. 2, curve *A* is for

(*a*) shear stress distribution

(*b*) velocity distribution

(*c*) pressure distribution

(*d*) none of the above.

201. Curve *B* in Fig. 2 is for

(*a*) shear stress distribution

(*b*) velocity distribution

(*c*) pressure distribution

(*d*) none of the above.

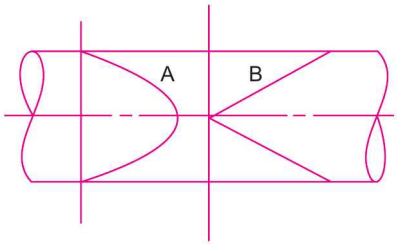

Fig. 2

202. Fig. 3 shows four curves for velocity distribution across a section for Reynolds number equal to 1000, 4000, 6000 and 10000. Curve *A* corresponds to Reynolds number equal to

(*a*) 1000 (*b*) 4000

(*c*) 6000 (*d*) 10000.

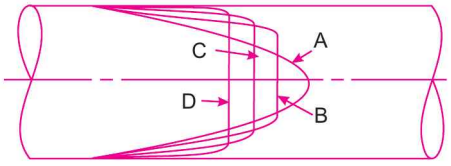

Fig. 3

203. Curve *B* in Fig. 3 corresponds to Reynolds number

(*a*) 1000 (*b*) 4000

(*c*) 6000 (*d*) 10000.

204. Curve *C* in Fig. 3 corresponds to the Reynolds number

(*a*) 1000 (*b*) 4000

(*c*) 6000 (*d*) 10000.

205. Curve *D* in Fig. 3 corresponds to the Reynold number

(*a*) 1000 (*b*) 4000

(*c*) 6000 (*d*) 10000.

206. The shear stress distribution across a section of a circular pipe, having viscous flow is given by

(*a*) $\tau = \frac{\partial p}{\partial x} r^2$ (*b*) $\tau = \frac{\partial p}{\partial x} \frac{r}{2}$

(*c*) $\tau = -\frac{\partial p}{\partial x} \frac{r}{2}$ (*d*) $\tau = -\frac{\partial p}{\partial x} \times 2r.$

207. The velocity distribution across a section of a circular pipe having viscous flow is given by

(*a*) $u = U_{max}\left[1 - \left(\frac{r}{R}\right)^2\right]$

(*b*) $u = U_{max}\,[R^2 - r^2]$

(*c*) $u = U_{max}\left[1 - \frac{r}{R}\right]^2$

(*d*) none of the above.

208. The velocity distribution across a section of two fixed parallel plates having viscous flow is given by

(*a*) $u = \frac{1}{2\mu}\left(-\frac{\partial p}{\partial x}\right)(t^2 - y^2)$

(*b*) $u = \frac{1}{2\mu}\frac{\partial p}{\partial x}\left[t_y - y^2\right]$

(*c*) $u = \frac{1}{2\mu}\frac{\partial p}{\partial x}\,[y - ty]$

(*d*) $u = -\frac{1}{2\mu}\frac{\partial p}{\partial x}[t - y^2]$

where t = Distance between two plates and y is measured from the lower plate.

209. The shear stress distribution across a section of two fixed parallel plates having viscous flow is given by

(*a*) $\tau = -\frac{1}{2}\frac{\partial p}{\partial x}[t^2 - y^2]$

(*b*) $\tau = -\frac{1}{2}\frac{\partial p}{\partial x}[t - 2y]$

(*c*) $\tau = -\frac{1}{2}\frac{\partial p}{\partial x}[ty - y^2]$

(*d*) $\tau = \frac{1}{2}\frac{\partial p}{\partial x}[y - ty]$

where t = Distance between two parallel plates and y is measured from the plate.

210. The ratio of inertia force to viscous force is known as
(*a*) Reynolds number (*b*) Froude number
(*c*) Mach number (*d*) Euler number.

211. The square root of the ratio of inertia force to gravity force is called
(*a*) Reynolds number (*b*) Froude number
(*c*) Mach number (*d*) Euler number.

212. The square root of the ratio of inertia force to force due to compressibility is known as
(*a*) Reynolds number (*b*) Froude number
(*c*) Mach number (*d*) Euler number.

213. The square root of the ratio of inertia force to pressure force is known as
(*a*) Reynolds number (*b*) Froude number
(*c*) Mach number (*d*) Euler's number.

214. Model analysis of pipes flow are based on
(*a*) Reynolds number (*b*) Froude number
(*c*) Mach number (*d*) Euler number.

215. Model analysis of free surface flows are based on
(*a*) Reynolds number (*b*) Froude number
(*c*) Mach number (*d*) Euler number.

216. Model analysis of aeroplanes and projectile moving at supersonic speed based on
(*a*) Reynolds number (*b*) Froude number
(*c*) Mach number (*d*) Euler number.

217. The boundary-layer takes place
(*a*) for ideal fluids
(*b*) for pipe-flow only
(*c*) for real fluids
(*d*) for flow over flat plate only.

218. The boundary layer is called turbulent boundary layer if
(*a*) Reynolds number is more than 2000
(*b*) Reynolds number is more than 4000
(*c*) Reynolds number is more than 5×10^5
(*d*) none of the above.

219. Laminar sub-layer exists in
(*a*) laminar boundary layer region
(*b*) turbulent boundary layer region
(*c*) transition zone
(*d*) none of the above.

220. The thickness of laminar boundary layer at a distance x from the leading edge over a flat plate varies as
(*a*) $x^{4/5}$ (*b*) $x^{1/2}$
(*c*) $x^{1/5}$ (*d*) $x^{3/5}$.

221. The thickness of turbulent boundary layer at a distance x from the leading edge over a flat plate varies as
(*a*) $x^{4/5}$ (*b*) $x^{1/2}$
(*c*) $x^{1/5}$ (*d*) $x^{3/5}$.

222. The separation of boundary layer takes place in case of
(*a*) negative pressure gradient
(*b*) positive pressure gradient
(*c*) zero pressure gradient
(*d*) none of the above.

223. The velocity profile for turbulent boundary layer is

(*a*) $\frac{u}{U} = \sin\left(\frac{\pi}{2}\frac{y}{\delta}\right)$

(*b*) $\frac{u}{U} = \left(\frac{y}{\delta}\right)^{4/7}$

(*c*) $\frac{u}{U} = 2\left(\frac{y}{\delta}\right) - \left(\frac{y}{\delta}\right)^2$

(*d*) $\frac{u}{U} = \frac{3}{2}\left(\frac{y}{\delta}\right) - \frac{1}{2}\left(\frac{y}{\delta}\right)^3$.

224. The drag force exerted by a fluid on a body immersed in the fluid is due to
(*a*) pressure and viscous force
(*b*) pressure and gravity force
(*c*) pressure and turbulence force
(*d*) none of the above.

225. For supersonic flow, if the area of flow increases then
(*a*) velocity decreases
(*b*) velocity increases
(*c*) velocity is constant
(*d*) none of the above.

226. The area velocity relationship for compressible fluids is

(*a*) $\frac{dA}{A} = \frac{dV}{A}[1 - M^2]$ (*b*) $\frac{dA}{A} = \frac{dV}{V}[M^2 - 1]$

(*c*) $\frac{dA}{A} = \frac{dV}{V}[1 - V^2]$ (*d*) $\frac{dA}{A} = \frac{dV}{V}[C^2 - 1]$.

227. The flow in open channel is laminar if the Reynolds number is
(*a*) 2000 (*b*) less than 2000
(*c*) less than 500 (*d*) none of the above.

228. The flow in open channel is turbulent if the Reynolds number is
(*a*) 2000 (*b*) more than 2000
(*c*) more than 4000 (*d*) 4000.

229. If the Froude number in open channel flow is less than 1.0, the flow is called
(*a*) critical flow
(*b*) super-critical flow
(*c*) sub-critical flow
(*d*) none of the above.

230. If the Froude number in open channel flow is equal to 1.0, the flow is called
(*a*) critical flow (*b*) streaming flow
(*c*) shooting (*d*) none of the above.

231. If the Froude number in open channel flow is more than 1.0, the flow is called
(*a*) critical flow (*b*) streaming flow
(*c*) shooting flow (*d*) none of the above.

232. Chezy's formula is given as
(*a*) $V = i\sqrt{mC}$ (*b*) $V = C\sqrt{mi}$
(*c*) $V = m\sqrt{Ci}$ (*d*) none of the above.

233. The discharge through a rectangular channel is maximum when
(*a*) $m = \frac{d}{3}$ (*b*) $m = \frac{d}{2}$
(*c*) $m = 2d$ (*d*) $m = \frac{3d}{2}$
where m = Hydraulic mean depth, d = Depth of flow.

234. The discharge through a trapezoidal channel is maximum when
(*a*) half of top width = sloping side
(*b*) top width = half of sloping side
(*c*) top width = 1.5 × sloping side
(*d*) none of the above.

235. The maximum velocity through a circular channel takes place when depth of flow is equal to
(*a*) 0.95 times the diameter
(*b*) 0.5 times the diameter
(*c*) 0.81 times the diameter
(*d*) 0.5 times the diameter.

236. The maximum discharge through a circular channel takes place when depth of flow is equal to
(*a*) 0.95 times the diameter
(*b*) 0.3 times the diameter
(*c*) 0.81 times the diameter
(*d*) 0.5 times the diameter.

237. Specific energy of a flowing fluid per unit weight is equal to
(*a*) $\frac{p}{w} + \frac{V^2}{2g}$ (*b*) $\frac{p}{w} + h$
(*c*) $\frac{V^2}{2g} + h$ (*d*) $\frac{p}{w} + \frac{V^2}{2g} + h$.

238. The depth of flow after hydraulic jump is
(*a*) $d_2 = \frac{d_1}{2}[\sqrt{1 + 8(F_e)_1^2} - 1]$
(*b*) $d_2 = \frac{d_1}{2}[1 + \sqrt{8(F_e)_1^2} - 1]$
(*c*) $d_2 = \frac{d_1}{2} + \sqrt{\frac{d_1^2}{4} + 8(F_e)_1}$
(*d*) none of the above.

239. The depth of flow at which specific energy is minimum is called
(*a*) normal depth (*b*) critical depth
(*c*) alternate depth (*d*) none of the above.

240. The critical depth (h_c) is given by
(*a*) $\left(\frac{q^2}{g}\right)^{1/2}$ (*b*) $\left(\frac{q}{g}\right)^{1/3}$
(*c*) $\left(\frac{q^2}{g}\right)^{1/3}$ (*d*) $\left(\frac{q^2}{g}\right)^{2/3}$
where q = Rate of flow per unit width of channel.

241. For a circular channel, the wetted perimeter is given by
(*a*) $\frac{R\theta}{2}$ (*b*) $3R\theta$
(*c*) $2R\theta$ (*d*) $R\theta$
where R = Radius of circular channel and θ = half the angle subtended by the water surface at the centre.

242. For a circular channel the area of flow is given by
(*a*) $R^2\left(2\theta - \frac{\sin 2\theta}{2}\right)$ (*b*) $R^2\left(\theta - \frac{\sin 2\theta}{2}\right)$
(*c*) $R^2(\theta - \sin 2\theta)$ (*d*) none of the above
where θ = Half the angle subtended by water surface at the centre, and R = Radius of circular channel.

243. The hydraulic mean depth is given by

(*a*) $\frac{P}{A}$ (*b*) $\frac{P^2}{A}$

(*c*) $\frac{A}{P}$ (*d*) $\sqrt{\frac{A}{P}}$

where A = Area , and P = Wetted perimeter.

244. A most economical section is one which for a given cross-sectional area, slope of bed (i) and co-efficient of resistance has

(*a*) maximum wetted perimeter
(*b*) maximum discharge
(*c*) maximum depth of flow
(*d*) none of the above.

245. Specific speed of a turbine is defined as the speed of the turbine which

(*a*) produces unit power at unit head
(*b*) produces unit horse power at unit discharge
(*c*) delivers unit discharge at unit head
(*d*) delivers unit discharge at unit power.

246. A pump is defined as a device which converts

(*a*) Hydraulic energy into mechanical energy
(*b*) Mechanical energy into hydraulic energy
(*c*) Kinetic energy into mechanical energy
(*d*) None of the above.

247. A turbine is a device which converts

(*a*) Hydraulic energy into mechanical energy
(*b*) Mechanical energy into hydraulic energy
(*c*) Kinetic energy into mechanical energy
(*d*) Electrical energy into mechanical energy.

248. The force exerted by a jet of water on a stationary vertical plate in the direction of jet is given by

(*a*) $F_x = \rho AV^2 \sin^2 \theta$

(*b*) $F_x = \rho AV^2 \ [1 + \cos \theta]$

(*c*) $F_x = \rho AV^2$

(*d*) none of the above.

249. The force exerted by a jet of water on a stationary inclined plate in the direction of jet is given by

(*a*) $F_x = \rho AV^2$

(*b*) $F_x = \rho AV^2 \sin^2 \theta$

(*c*) $F_x = \rho AV^2 \ [1 + \cos \theta]$

(*d*) $F_x = \rho AV^2 \ [1 + \sin \theta]$.

250. The force exerted by a jet of water on a stationary curved plate in the direction of jet is equal to

(*a*) ρAV^2

(*b*) $\rho AV^2 \sin^2 \theta$

(*c*) $\rho AV^2 \ (1 + \cos \theta)$

(*d*) $\rho AV^2 \ [1 + \sin \theta]$.

251. The force exerted by a jet of water having velocity V on a vertical plate, moving with a velocity u is given by

(*a*) $F_x = \rho A(V - u)^2 \sin^2 \theta$
(*b*) $F_x = \rho A(V - u)^2$
(*c*) $F_x = \rho A(V - u)^2 \ [1 + \cos \theta]$
(*d*) None of the above.

252. The force exerted by a jet of water having velocity V on a series of vertical plates moving with velocity u is given by

(*a*) $F_x = \rho AV^2$ (*b*) $F_x = \rho A \ (V - u)^2$
(*c*) $F_x = \rho AVu$ (*d*) None of the above.

253. Efficiency of the jet of water having velocity V striking a series of vertical plates moving with a velocity u is given by

(*a*) $\eta = \frac{2V \ (V - u)}{u^2}$ (*b*) $\eta = \frac{2u(V - u)}{V^2}$

(*c*) $\eta = \frac{u^2}{V^2 \ (V - u)}$ (*d*) None of the above.

254. Efficiency, of the jet of water having velocity V and striking a series of vertical plates moving with a velocity u, is maximum when

(*a*) $u = 2V$ (*b*) $u = \frac{V}{2}$

(*c*) $u = \frac{3V}{2}$ (*d*) $u = \frac{4V}{3}$.

255. Maximum efficiency of a series of vertical plates is

(*a*) 66.67% (*b*) 33.33%
(*c*) 50% (*d*) 80%.

256. For a series of curved radial vanes, the work done per second per unit weight is equal to

(*a*) $\frac{1}{g} V_{W_1} u_1 + V_{W_2} u_2$ (*b*) $\frac{1}{g}[V_1 u_1 + V_2 u_2]$

(*c*) $\frac{1}{g}[V_{W_1} u_1 \pm V_{W_2} u_2]$ (*d*) none of the above.

257. The net head (H) on the turbine is given by

(*a*) H = Gross Head + Head lost due to friction
(*b*) H = Gross Head – Head lost due to friction

(*c*) H = Gross Head + $\frac{V^2}{2g}$ – Head lost due to friction.

258. Hydraulic efficiency of a turbine is defined as the ratio of
(*a*) Power available at the inlet of turbine to power given by water to the runner
(*b*) Power at the shaft of the turbine to power given by water to the runner
(*c*) Power at the shaft of the turbine to the power at the inlet of turbine
(*d*) None of the above.

259. Mechanical efficiency of a turbine is the ratio of
(*a*) Power at the inlet to the power at the shaft of turbine
(*b*) Power at the shaft to the power given to the runner
(*c*) Power at the shaft to the power at the inlet of turbine
(*d*) None of the above.

260. The overall efficiency of a turbine is the ratio of
(*a*) Power at the inlet of turbine to the power at the shaft
(*b*) Power at the shaft to the power given to the runner
(*c*) Power at the shaft to the power at the inlet of turbine
(*d*) None of the above.

261. The relation between hydraulic efficiency (η_h), mechanical efficiency (η_m) and overall efficiency (η_o) is
(*a*) $\eta_h = \eta_o \times \eta_m$ (*b*) $\eta_o = \eta_h \times \eta_m$
(*c*) $\eta_o = \frac{\eta_m}{\eta_h}$ (*d*) none of the above.

262. A turbine is called impulse if at the inlet of the turbine
(*a*) total energy is only kinetic energy
(*b*) total energy is only pressure energy
(*c*) total energy is the sum of kinetic energy and pressure energy
(*d*) none of the above.

263. A turbine is called reaction turbine if at the inlet of the turbine the total energy is
(*a*) kinematic energy only
(*b*) kinetic energy and pressure energy
(*c*) pressure energy only
(*d*) none of the above.

264. Which of the following statement is correct?
(*a*) Pelton wheel is a reaction turbine
(*b*) Pelton wheel is a radial flow turbine
(*c*) Pelton wheel is an impulse turbine
(*d*) None of the above.

265. Francis turbine is
(*a*) an impulse turbine
(*b*) a radial flow impulse turbine
(*c*) an axial flow turbine
(*d*) a reaction radial flow turbine.

266. Kaplan turbine is
(*a*) an impulse turbine
(*b*) a radial flow impulse turbine
(*c*) an axial flow reaction turbine
(*d*) a radial flow reaction turbine.

267. Jet ratio (m) is defined as the ratio of
(*a*) diameter of jet of water to diameter of Pelton wheel
(*b*) velocity of vane to the velocity of jet of water
(*c*) velocity of flow to the velocity of jet of water
(*d*) diameter of Pelton wheel to diameter of the jet of water.

268. Flow ratio is defined as the ratio of
(*a*) Velocity of flow at inlet to the velocity given by $\sqrt{2gH}$
(*b*) Velocity of runner at inlet to the velocity of flow at inlet
(*c*) Velocity of runner to the velocity given by $\sqrt{2gH}$
(*d*) None of the above.

269. Speed ratio is given by
(*a*) $\frac{u}{\sqrt{2gH}}$ (*b*) $\frac{V_f}{\sqrt{2gH}}$
(*c*) $\frac{\sqrt{2gH}}{V_f}$ (*d*) $\frac{V_w}{\sqrt{2gH}}$.

270. The speed ratio for Pelton wheel varies from
(*a*) 0.45 to 0.50 (*b*) 0.6 to 0.7
(*c*) 0.3 to 0.4 (*d*) 0.8 to 0.9.

271. The discharge through Pelton Turbine is given by
(*a*) $Q = \pi DB\, V_f$
(*b*) $Q = \frac{\pi}{4} d^2 \times \sqrt{2gH}$
(*c*) $Q = \frac{\pi}{4}\left[D_o^2 - D_b^2\right] \times V_f$
(*d*) None of the above.

272. The discharge through Francis Turbine is given by
(*a*) $Q = \pi DB\, V_f$
(*b*) $Q = \frac{\pi}{4} d^2 \times \sqrt{2gH}$
(*c*) $Q = \frac{\pi}{4}\left[D_o^2 - D_b^2\right]$
(*d*) None of the above.

273. The discharge through Kaplan turbine is given by
(*a*) $Q = \pi DB\, V_f$ (*b*) $Q = \frac{\pi}{4} d^2 \times \sqrt{2gH}$
(*c*) $Q = \frac{\pi}{4}\left[D_o^2 - D_b^2\right]$ (*d*) $Q = 0.9\, \pi DB\, V_f$.

274. Draft tube is used for discharging water from the exit of
(*a*) an impulse turbine (*b*) a Francis turbine
(*c*) a Kaplan turbine (*d*) a Pelton wheel.

275. Specific speed of a turbine is defined as the speed at which the turbine runs when
(*a*) working under unit head and discharging one litre per second
(*b*) working under unit head and develops unit horse power
(*c*) develops unit horse power and discharges one litre per second
(*d*) none of the above.

276. The specific speed (N_s) of a turbine is given by
(*a*) $N_s = \frac{N\sqrt{P}}{H^{3/4}}$ (*b*) $N_s = \frac{N\sqrt{Q}}{H^{3/4}}$
(*c*) $N_s = \frac{N\sqrt{P}}{H^{5/4}}$ (*d*) $N_s = \frac{NP^{5/4}}{\sqrt{H}}$.

277. Unit speed is the speed of a turbine when it is working
(*a*) under unit head and develops unit power
(*b*) under unit head and discharge one m^3/sec
(*c*) under unit head
(*d*) none of the above.

278. Unit discharge is the discharge of a turbine when
(*a*) the head on turbine is unity and it develops unit power
(*b*) the head on turbine is unity and it moves at unit speed
(*c*) the head on the turbine is unity
(*d*) none of the above.

279. Unit power is the power developed by a turbine when
(*a*) head on turbine is unity and discharge is also unity
(*b*) head = one metre and speed is unity
(*c*) head on turbine is unity
(*d*) none of the above.

280. The unit speed (N_u) is given by the expression
(*a*) $N_u = \frac{N}{H^{3/2}}$ (*b*) $N_u = \frac{N}{H^{3/4}}$
(*c*) $N_u = \frac{N}{\sqrt{H}}$ (*d*) $N_u = \frac{N}{H^{5/4}}$.

281. The unit discharge (Q_u) is given by the expression
(*a*) $Q_u = \frac{Q}{\sqrt{H}}$ (*b*) $Q_u = \frac{Q}{H^{3/2}}$
(*c*) $Q_u = \frac{Q}{H^{3/4}}$ (*d*) $Q_u = \frac{Q}{H^{5/4}}$.

282. Unit power (P_u) is given by the expression
(*a*) $P_u = \frac{P}{\sqrt{H}}$ (*b*) $P_u = \frac{P}{H^{3/2}}$
(*c*) $P_u = \frac{P}{H^{3/4}}$ (*d*) $P_u = \frac{P}{H^{5/4}}$.

283. The unit discharge (Q_u) and unit speed (N_u) curves for different turbines are shown in Fig. 4. Curve *A* is for
(*a*) Francis Turbine
(*b*) Kaplan Turbine
(*c*) Pelton Turbine
(*d*) Propeller Turbine.

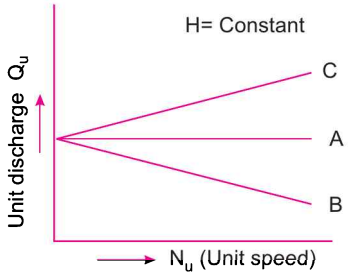

Fig. 4

284. Curve *B* in Fig. 4 is for
(*a*) Francis Turbine
(*b*) Kaplan Turbine
(*c*) Pelton Turbine
(*d*) Propeller Turbine.

285. Curve *D* in Fig. 4 is for
(*a*) Francis Turbine
(*b*) Kaplan Turbine
(*c*) Pelton Turbine
(*d*) Propeller Turbine.

286. Tick mark the correct statement
(*a*) curves at constant speed are called main characteristic curves
(*b*) curves at constant head are called main characteristic curves
(*c*) curves at constant efficiency are called operating characteristic curves
(*d*) curves at constant efficiency are called main characteristic curves.

287. Main characteristic curves of a turbine means
(*a*) curves at constant speed
(*b*) curves at constant efficiency
(*c*) curves at constant head
(*d*) none of the above.

288. Operating characteristic curves of a turbine means
(*a*) curves drawn at constant speed
(*b*) curves drawn at constant efficiency
(*c*) curves drawn at constant head
(*d*) none of the above.

289. Muschel curves means
(*a*) curves at constant head
(*b*) curves at constant speed
(*c*) curves at constant efficiency
(*d*) none of the above.

290. Governing of a turbine means
(*a*) the head is kept constant under all condition of working
(*b*) the speed is kept constant under all conditions
(*c*) the discharge is kept constant under all conditions
(*d*) none of the above.

291. The work done by impeller of a centrifugal pump on water per second per unit weight of water is given by
(*a*) $\frac{1}{g}V_{W_1}u_1$ (*b*) $\frac{1}{g}V_{W_2}u_2$
(*c*) $\frac{1}{g}(V_{W_2}u_2 - V_{W_1}u_1)$ (*d*) none of the above.

292. The manometer head (H_m) of a centrifugal pump is given by
(*a*) Pressure head at outlet of pump – pressure head at inlet
(*b*) Total head at inlet – total head at outlet
(*c*) Total head at outlet – total head at inlet
(*d*) None of the above.

293. The manometric efficiency (η_{man}) of a centrifugal pump is given by
(*a*) $\frac{H_m}{gV_{W_2}u_2}$ (*b*) $\frac{gH_m}{V_{W_2}u_2}$
(*c*) $\frac{V_{W_2}u_2}{gH_m}$ (*d*) $\frac{g \times V_{W_2}u_2}{H_m}$.

294. Mechanical efficiency (η_{mech}) of a centrifugal pump is given by
(*a*) (Power at the impeller)/S.H.P.
(*b*) S.H.P./Power at the impeller
(*c*) Power possessed by water/power at the impeller
(*d*) Power possessed by water/S.H.P.

295. To produce a high head by multistage centrifugal pumps, the impellers are connected
(*a*) in parallel
(*b*) in series
(*c*) in parallel and in series both
(*d*) none of the above.

296. To discharge a large quantity of liquid by multi-stage centrifugal pump, the impellers are connected
(*a*) in parallel
(*b*) in series
(*c*) in parallel and in series
(*d*) none of the above.

297. Specific speed of a pump is the speed at which a pump runs when
(*a*) head developed is unity and discharge is one cubic metre
(*b*) head developed is unity and shaft horse power is also unity
(*c*) discharge is one cubic metre and shaft horse power is unity
(*d*) none of the above.

298. The specific speed (N_s) of a pump is given by the expression
(*a*) $N_s = \frac{N\sqrt{Q}}{H_m^{5/4}}$ (*b*) $N_s = \frac{N\sqrt{P}}{H_m^{3/4}}$
(*c*) $N_s = \frac{N\sqrt{Q}}{H_m^{3/4}}$ (*d*) $N_s = \frac{N\sqrt{P}}{H_m^{5/4}}$.

299. The operating characteristic curves of a centrifugal pump are shown in Fig. 5, curve *A* is for
(*a*) Head (*b*) Efficiency
(*c*) Power (*d*) None of the above.

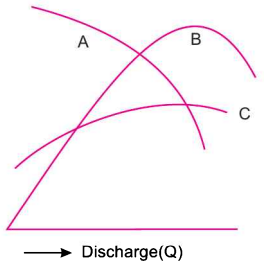

Fig. 5

300. Curve *B* in Fig. 5 is for
(*a*) Head (*b*) Efficiency
(*c*) Power (*d*) None of the above.

301. Curve *C* in Fig. 5 is for
(*a*) Head (*b*) Efficiency
(*c*) Power (*d*) None of the above.

302. Cavitation will take place if the pressure of the flowing fluid at any point is
(*a*) more than vapour pressure of the fluid
(*b*) equal to vapour pressure of the fluid
(*c*) is less than vapour pressure of the fluid
(*d*) none of the above.

303. Cavitation can take place in case of
(*a*) Pelton Wheel
(*b*) Francis Turbine
(*c*) Reciprocating pump
(*d*) Centrifugal pump.

304. Which of the following statement is correct?
(*a*) Centrifugal pump convert mechanical energy into hydraulic energy by sucking liquid into chamber
(*b*) Reciprocating pumps convert mechanical energy into hydraulic energy by means of centrifugal force.
(*c*) Centrifugal pumps convert mechanical energy into hydraulic energy by means of centrifugal force
(*d*) Reciprocating pumps convert hydraulic energy into mechanical energy.

305. The discharge through a single-acting reciprocating pump is
(*a*) $Q = \frac{ALN}{60}$ (*b*) $Q = \frac{2ALN}{60}$
(*c*) $Q = ALN$ (*d*) $Q = 2ALN$.

306. The pressure head due to acceleration (h_a) in reciprocating pump is given by
(*a*) $h_a = \frac{l}{g} \times \frac{a}{A} \times \omega^2 r \sin\theta$
(*b*) $h_a = \frac{l}{g} \times \frac{A}{a} \times \omega^2 r \sin\theta$
(*c*) $h_a = \frac{l}{g} \times \frac{A}{a} \omega^2 r \cos\theta$
(*d*) $h_a = \frac{A}{a} \omega^2 r \sin\theta$
where A = Area of cylinder, a = Area of pipe and r = radius of crank.

307. Indicator diagram shows for one complete revolution of crank the
(*a*) Variation of kinetic head in the cylinder
(*b*) Variation of pressure head in the cylinder
(*c*) Variation of kinetic and pressure head in the cylinder
(*d*) None of the above.

308. Air vessel in a reciprocating pump is used
(*a*) to obtain a continuous supply of water at uniform rate
(*b*) to reduce suction head
(*c*) to increase the delivery head
(*d*) none of the above.

309. The work saved by fitting an air vessel to a single-acting reciprocating pump is
(*a*) 39.2% (*b*) 84.4%
(*c*) 48.8% (*d*) 92.3%.

310. The work saved by fitting an air vessel to a double acting reciprocating pump is
(*a*) 39.2% (*b*) 84.8%
(*c*) 48.8% (*d*) 92.3%.

311. The pressure, at which separation takes place, is known as separation pressure or separation pressure head. For water, the limiting value of separation pressure head is
(*a*) 2.5 m (abs.) (*b*) 7.5 m (abs.)
(*c*) 10.3 m (abs.) (*d*) 5 m (abs.)

312. During suction stroke of a reciprocating pump, the separation may take place
(*a*) at the end of suction stroke
(*b*) in the middle of suction stroke
(*c*) in the beginning of suction stroke
(*d*) none of the above.

313. During delivery stroke of a reciprocating pump, the separation may take place
(*a*) at the end of delivery stroke
(*b*) in the middle of delivery stroke
(*c*) in the beginning of the delivery stroke
(*d*) none of the above.

314. Hydraulic accumulator is a device used for
(*a*) lifting heavy weights
(*b*) storing the energy of a fluid in the form of pressure energy
(*c*) increasing the pressure intensity of a fluid
(*d*) none of the above.

315. Hydraulic intensifier is a device used for
(*a*) storing energy of a fluid in the form of pressure energy
(*b*) increasing pressure intensity of a liquid
(*c*) transmitting power from one shaft to another
(*d*) none of the above.

316. Hydraulic ram is pump which works
(*a*) on the principle of water-hammer
(*b*) on the principle of centrifugal action
(*c*) on the principle of reciprocating action
(*d*) none of the above.

317. Hydraulic coupling is a device used for
(*a*) transmitting same torque to the driven shaft
(*b*) transmitting increased torque to the driven shaft
(*c*) transmitting decreased torque to the driven shaft
(*d*) none of the above.

318. Torque converter is a device used for
(*a*) transmitting same torque to the driven shaft
(*b*) transmitting increased torque to the driven shaft
(*c*) transmitting decreased torque to the driven shaft
(*d*) transmitting increased or decreased torque to the driven shaft.

319. Capacity of a hydraulic accumulator is given as equal to
(*a*) pressure of water supplied by pump × volume of accumulator
(*b*) pressure of water × area of accumulator
(*c*) pressure of water × stroke of the ram of accumulator
(*d*) none of the above.

320. Kaplan turbine is a propeller turbine in which the vanes fixed on the hub are
(*a*) non-adjustable (*b*) adjustable
(*c*) fixed (*d*) none of the above.

321. If the head on the turbine is more than 300 m, the type of turbine used should be
(*a*) Kaplan (*b*) Francis
(*c*) Pelton (*d*) Propeller.

322. If the specific speed of a turbine is more than 300, the type of turbine is
(*a*) Pelton
(*b*) Kaplan
(*c*) Francis
(*d*) Pelton with more jets.

323. Run-away speed of a Pelton wheel means
(*a*) Full load speed
(*b*) No load speed
(*c*) No load speed with no governor mechanism
(*d*) None of the above.

324. Spouting velocity means
(*a*) actual velocity of jet
(*b*) ideal velocity of jet
(*c*) half of ideal velocity of jet
(*d*) none of the above.

325. Surge tank in a pipe line is used to
(*a*) reduce the loss of head due to friction in pipe
(*b*) make the flow uniform in pipe
(*c*) relieve the pressure due to water hammer
(*d*) none of the above.

326. Hydraulic ram is a device used for
(*a*) storing energy of a water in the form of pressure energy
(*b*) increasing pressure intensity of water
(*c*) lifting small quantity of water to a greater height by means of large quantity of water falling through small height
(*d*) none of the above.

327. For low head and high discharge, the suitable turbine is
(*a*) Pelton (*b*) Francis
(*c*) Kaplan (*d*) None of the above.

328. For high head and low discharge, the suitable turbine is
(*a*) Pelton (*b*) Francis
(*c*) Kaplan (*d*) None of the above.

329. The flow of water, leaving the impeller, in a centrifugal pump casing is
(*a*) Forced vortex flow
(*b*) Free vortex flow
(*c*) Centrifugal flow
(*d*) None of the above.

330. Rotameter is used for measuring
(*a*) density of fluids
(*b*) velocity of fluids in pipes
(*c*) discharge of fluids
(*d*) viscosity of fluids.

331. A current meter is a device used for measuring
(*a*) velocity (*b*) viscosity
(*c*) current (*d*) pressure.

332. A hot wire anemometer is a device used for measuring
(*a*) viscosity (*b*) velocity of gases
(*c*) pressure of gases (*d*) none of the above.

APPENDIX

(A) Base and Derived Units in MKS and SI Units :

S. No.	*Physical Quantity*	*Unit Symbol in MKS Units*	*Unit Symbol in SI Units*	*Name*
1.	Mass	kg (*M*)	kg(*M*)	kilogram
2.	Length	m (*L*)	m (*L*)	metre
3.	Time	Sec (*t*)	s (*t*)	second
4.	Force	kgf	N	newton
5.	Work, energy	kgf-m	Nm = J	joule
6.	Power	kgf-m/sec	Nm/s =J/s = W	watt

(B) Conversion Factors from MKS to SI Units :

$$1 \text{ kgf} = 9.81 \text{ N}$$

$$1 \text{ kgf-m} = 9.81 \text{ N m} = 9.81 \text{ J}$$

$$1 \text{ kgf-m/sec} = 9.81 \text{ N m/s} = 9.81 \text{ J/s} = 9.81 \text{ W}$$

$$1 \text{ metric h.p.} = 75 \text{ kgf-m/sec} = 75 \times 9.81 \text{ N m/s}$$

$$= 735.75 \text{ N m/sec} \simeq 736 \text{ W} \qquad (\because \text{ N m/s = W})$$

(C) Conversion Factors from MKS to CGS Units :

$$1 \text{ kgf} = 1000 \text{ gmf} = 1000 \times \text{gm} \times \text{g}$$

$$= 1000 \times \text{gm} \times 981 \text{ cm/sec}^2$$

$$= 1000 \times 981 \times \text{gm-cm/sec}^2 = 1000 \times 981 \text{ dyne}$$

$$= 9.81 \times 10^5 \text{ dyne} \qquad (\because \text{ gm-cm/sec}^2 = \text{dyne})$$

$$1 \text{ kgf/m}^2 = 9.81 \times 10^5 \text{ dyne}/10^4 \text{ cm}^2 \qquad (\because \text{ m}^2 = 10^4 \text{ cm}^2)$$

$$= 9.81 \times 10 \text{ dyne/cm}^2 = 98.1 \text{ dyne/cm}^2$$

$$1 \text{ m}^3 = 1000 \text{ litre.}$$

(D) Conversion Factors for Poise and Stoke in MKS and SI Units :

$$\text{Poise} = \frac{1}{98.1} \text{ (MKS unit)} = \frac{1}{10} \text{ (SI unit)}$$

$$\text{Stoke} = 10^{-4} \text{ (MKS unit)} = 10^{-4} \text{ (SI unit)}$$

(E) Important Values in S.I. Units :

$$\text{Pascal (Pa)} = \text{N/m}^2 = \text{kg/ms}^2$$

$$\text{Newton (N)} = \text{kg m/s}^2$$

$$\text{Joule (J)} = \text{N m} = \text{kg m}^2/\text{s}^2.$$

$$\text{Atmospheric pressure} = 101.325 \text{ kN/m}^2$$

$$1 \text{ bar} = 10^5 \text{ Pa} = 10^5 \text{ N/m}^2$$

$$1 \text{ m bar or } 1 \text{ mb} = 10^{-3} \text{ bar} = 10^2 \text{ Pa} = 10^2 \text{ N/m}^2$$

Pascal and bar are used for pressure.

An Introduction To Microprocessor 8085
Dr. D.K. Kaushik

Dr. D. K. Kaushik is presently working as the Principal, Manohar Memorial Post-Graduate College, Fatehabad (Haryana). Earlier, he was the Head, Department of Electronics, Dayanand Post-Graduate College, Hisar. He obtained his master's degree in Physics from Meerut University and Ph.D. in 1981 from Kurukshetra University, Kurukshetra. He has more than 28 years teaching experience in the subject of Electronics and published more than 24 research papers in journals of high repute. He has two patents for indigenous design of Electronic Thin Film Thickness Monitors, to his credit. He had been the Member board of studies in Electronics of Kurukshetra University, Kurukshetra many times. His areas of interest are Semiconductor Electronics, Microprocessor, Computer Architecture and Thin Film Technology.

AN INTRODUCTION TO MICROPROCESSOR 8085

1

Evolution and History of Microprocessors

To understand the working and programming of microprocessors, it is very necessary to know the details of evolution and history of microprocessors which will be discussed in this chapter. In the succeeding chapters of this book, the detailed discussion on the basics of microprocessors will be made. For the beginners it is very difficult to understand the operation of a digital computer as it contains large details, so efforts have been made to envisage the operation of a digital computer in step by step manner.

1.1 INTRODUCTION

Microprocessor is a digital device on a chip which can fetch instructions from a memory, decode and execute them i.e. performs certain arithmetic and logical operations, accept data from input device, and send results to output devices. Therefore, a microprocessor interfaced with memory and Input/ Output devices forms a Microcomputer. Basically, there are five building blocks of a digital computer namely:

Input Unit Through this unit data and instructions are fed to the memory of the computer. The basic purpose of this unit is to read the data into the machine. The program from the memory is read into the machine along with the input data which are required to solve or compute the problem by the machine. The typical devices which are used for this purpose are keyboards, paper tape reader and toggle switches etc.

Memory Unit The memory unit of a digital computer consists of devices which are capable of storing information. The memory of a computer is used for storing two distinct type of information such as data to be processed by the computer and program through which the result of the desired problem is obtained. Computer program and data are stored in the Memory Unit. This usually consists of chips of both ROMs (Read Only Memories) and RAMs (Random Access Memories) either bipolar or MOS.

Arithmetic and Logical Unit (ALU)

This unit is used for performing arithmetic operations such as Addition, Subtraction, Multiplications, division and other logical operations on the data.
The control unit guides ALU which of the operations are to be performed. The sequence of the instructions is controlled by the control unit.

Control Unit

The control unit performs the most important function in a computer. It controls all other units and also controls the flow of data from one unit to another for performing computations. It also sequences the operations. It instructs all the units to perform the task in a particular sequence with the help of clock pulses.

Output Unit

After processing of the data in the Arithmetic and Logical Unit, the results are displayed to the output world through this unit. The CRTs (Cathode Ray Tubes), LEDs (Light Emitting Diodes) and Printer etc. form the output unit.

In a computer system ALU and Control Unit are combined in one unit called Central Processing Unit (CPU). The block diagram of a computer is shown in figure 1.1.

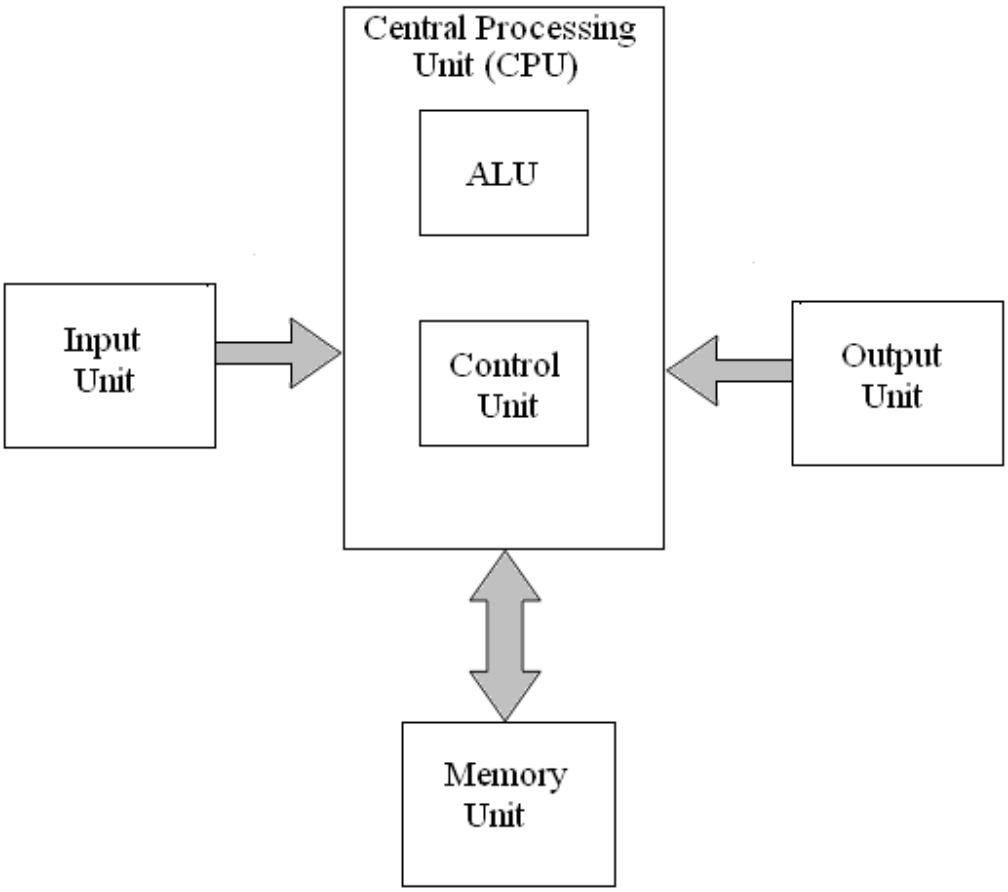

Fig. 1.1

The Central Processing Unit is analogous to the human brain as all the decisions as per the instructions are made by CPU. All other parts are also controlled by this unit. A microprocessor is an integrated circuit designed for use as Central Processing Unit of a computer. The CPU is the primary and central player in communicating with devices such as memory, input and output. However, the timing of communication process is controlled by the group of circuits called control unit.

The term 'Microprocessor' came into existence, in 1971, when the Intel Corporation of America, developed the first microprocessor (INTEL-4004) which is a 4-bit microprocessor (μ**p**). A microprocessor is a programmable digital electronic component that incorporates the functions of a Central Processing Unit (CPU) on single semi-conducting Integrated Circuits (ICs). As such, a system with microprocessor as an integral part is termed as a microprocessor based system. When a computer is microprocessor based, it is called a microcomputer (μ**c**).

A microprocessor is specified by its 'Word Size', e.g. 4-bit, 8-bit, 16-bit etc. By the term 'word size" means the number of bits of data that is processed by the microprocessor as a unit. For example, an 8-bit microprocessor performs various operations on 8-bit data. It also specifies the width of the data bus. As discussed above, a microcomputer consists of input/ output devices, and memory, in addition to microprocessor which acts its CPU. In fact CPU is commonly referred to microprocessor (μ**p**)**.** Microprocessors made possible the advent of the microcomputer in the mid-1970s. Before this period, electronic CPUs were typically made from bulky discrete switching devices. Later on small-scale integrated circuits were used to design the CPUs. By integrating the processor onto one or very few large-scale integrated circuit package (containing the equivalent of thousands or millions of discrete transistors), the cost of processor was greatly reduced.

The evolution of microprocessors has been known to follow Moore's law when it comes to steadily increasing performance over the years. This law suggests that the complexity of an integrated circuit, with respect to minimum component cost, doubles in every 18 months. This dictum has generally proven true since the early 1970's. This lead to the dominance of microprocessors over every other form of computer; every system from the largest mainframes to the smallest hand held computers now uses a microprocessor as its core.

The microprocessor based systems play significant role in the every functioning of industrialized societies. The microprocessor can be viewed as a programmable logic device that can be used to control processes or to turn on/off devices. So the microprocessor can be viewed as a data processing unit or a computing unit of a computer. The microprocessor is a programmable integrated device that has computing and decision making capability similar to that of the central processing unit (CPU) of a computer. Nowadays, the microprocessor is being used in a wide range of products called microprocessor based products or systems. The microprocessor communicates and operates in the binary numbers 0 and 1, called bits. Each microprocessor has a fixed set

of instructions in the form of binary pattern called a machine language. However, it is difficult for human beings to communicate in the language of 0s and 1s. Therefore, the binary instructions are given abbreviated names, called mnemonics, which form the assembly language for a given microprocessor.

1.2 EVOLUTION/HISTORY OF MICROPROCESSORS

An English Mathematician Charles Babbage was the first man to propose the basic principle of modern computers from 1792-1871. He gave the concept of a programmable machine having computer similar to modern digital computers. He is, therefore, known Father of Modern Computers. In 1930s successful general purpose mechanical computer was developed. Before this, mechanical calculators were built to perform simple mathematical operations such as addition, subtraction, multiplication and division. Improvement continued and in 1944 Prof. H. Aiken developed a first practical electro-mechanical digital computer in collaboration with IBM. This computer was known as HAWARD MARK-I. It was in large size (51' long and 8'high) and weighing about 2 tons. The punch cards ware used to input the data in the computer.

During the development of the HAWARD MARK-I Computer, Konard Joos of Germany was busy in developing another computer based on 0's and 1's rather than decimal numbers. So he developed a computer making use of relays (on-off for 1's and 0's) during 1936-44. Joos also developed a language for the computer. The giant machines during 1940-50 were thus designed using relays and vacuum tubes.

In 1945, John J. Mauchy and J. Presper Eckert of University of Pennsylvania developed first electronic computer ENIAC (Electronic Numerical Integrator and Calculator). It was too huge weighing 30 tons and occupied an area $30' X 50'$ and made use of 18000 vacuum tubes, more than 30000 resistors, 10000 capacitors and 6000 switches. It took 200 μS for addition, and 3mS for 10-digit multiplication. It had separate memory for program and data. It used 20 electronic accumulators for memory. Each accumulator stored signed 10-digit decimal number. A number of computers using vacuum tubes were developed during 1940-55. The main drawback with the ENIAC was the life of the vacuum tube components, which required the frequent maintenance.

The invention of semiconductor transistors in 1948 at Bell Laboratories leads further development of computers. The use of semiconductor transistors could not only reduced the size of computers but also increased its capability to a great extent. This leads reduction in cost. Further, the invention of Integrated circuits in 1958 by Jack Kilby of Texas Instrument made a revolution in electronic circuitry. The use of ICs made the size of computers very small and became more versatile in functions. Finally, the advent of IC technology leads to the development of first microprocessor (INTEL 4004) in 1971 at Intel Corporation by an engineer Marcian E. Hoff. It was a 4-bit microprocessor – a programmable controller on a chip. This was called the first generation microprocessor. It was fabricated using P-channel MOSFET technology and had an instruction set of 45 different instructions. It addressed 4096 four-bit wide memory locations. The P-channel MOSFET technology gave low cost but low speed not compatible with TTL (Transistor-

Transistor Logic) technology. It has to use at least 30 ICs to form a system. As INTEL 4004 had very small number of instructions, it could be used in limited applications such as early video games and small microprocessor-based controllers. Seeing microprocessor as a viable product, Intel Corporation released the 8008 microprocessor – an extended 8 bit version of the 4004 microprocessor in 1972. Soon a variety of microprocessors was released by different manufactures. A few first generation microprocessors are listed in table 1.1.

Table 1.1

4-bit Microprocessors	8-bit Microprocessors
INTEL 4004	INTEL 8008
INTEL 4040	NATIONAL IMP-8
FAIRCHILD PPS-25	ROCKWELL PPS-8
ROCKWELL PPS-4	AMI 7200
NATIONAL IMP-4	MOSTEK 5065

Second generation microprocessors appeared in 1973 and used NMOS-technology which offered faster speed, higher density and still better reliability. In the year 1974, an 8-bit microprocessor INTEL 8080 was developed using NMOS technology. It requires only two additional devices to design a functional CPU. It is much faster than 8008 and has more instructions than 8008 that facilitates the programming. The 8080 was compatible with TTL, whereas the 8008 was not directly compatible. The 8080 microprocessor could also address four times more memory (64K bytes) than the 8008 microprocessor (16K bytes). INTEL Corporation in 1977 developed another 8-bit microprocessor 8085 which was proved to be a better version than 8080. The execution time of two 8-bit numbers is 2.0 μS for 8085 whereas it is 1.3 μS for 8080. The main advantages of the 8085 were its internal clock generator, internal system controller, and higher clock frequency. Some of the important second generation microprocessors are given in table 1.2.

Table 1.2

8-bit Microprocessors	12-bit Microprocessors
INTEL 8080	INTERSIL 6100
INTEL 8085	TOSHIBA TLCS-12
FAIRCHILD F8	
MOTOROLA M6800	
ZILOG Z-80	
SIGNETICS 2650	

The advantages of second generation microprocessor are given below:

(i) Larger chip size (170 X 200 mils),
(ii) 40 pins,
(iii) More number of on-chip decoded timing signals,
(iv) Ability to address larger memory space,
(v) Ability to address more I/O Ports,
(vi) More powerful instruction set,
(vii) Faster operation,
(viii) Better Interrupt handling capabilities.

Third generation microprocessors were introduced in 1978. These were 16-bit microprocessors, designed using HMOS (High Density MOS) technology. These microprocessors offered better speed and higher packing density than NMOS. Some important third generation microprocessors are given in table 1.3.

Table 1.3

16-bit Microprocessors		
INTEL 8086 INTEL 8088 INTEL 80186 INTEL 80286	MOTOROLA-68000 MOTOROLA-68010 NATIONAL NS-16016 TEXAS INSTRUMENT-TMS-99000	INTERSIL 6100 TOSHIBA TLCS-12 ZILOG Z-8000

In 1978, 16-bit INTEL 8086 microprocessor of 64 pins was introduced and in 1979 other 16-bit microprocessor 8088 was developed. In addition to the other performances, these µPs contain multiply/divide/arithmetic hardware. The memory addressing capabilities has been increased to very large i.e., 1MB to 16MB through a variety of flexible and powerful addressing mode. The other characteristics of third generation are given below:

(i) These microprocessors were 40/48/64 pins,
(ii) High speed and very strong processing capability,
(iii) Easier to program,
(iv) Allow for dynamically re-locatable programs,
(v) Size of internal registers were 8/16/32 bits,
(vi) These µPs had the multiply/divide/arithmetic hardware,
(vii) Physical memory space was from 1 to 16 Mega-bytes (MB),
(viii) Flexible 10 port addresses,
(ix) More powerful interrupt and hardware capabilities,
(x) Segmented address and virtual memory features.

Fourth generation microprocessors of 32 bits were introduced in the form of 80386 in 1985 and 80486 in 1989. The instruction set of the 80386 microprocessor was upward compatible with the earlier 8086, 8088 and 80286 microprocessors. However, the 80486 is an improved version of the 80386 microprocessor. The 80386 executes many instructions in 2 clock cycles while the 80486 executes in one clock cycle. These microprocessors are of low power version of HMOS technology. Some important fourth generation microprocessors are given in table 1.4.

Table 1.4

32-bit Microprocessors	
INTEL 80386 INTEL 80486 NATIONAL NS16022 MOTOROLA MC 88100	MOTOROLA M-68020 MOTOROLA M-68030 BELLMAC-32

Fifth generation microprocessor was introduced by INTEL Corporation in 1993 in the form of PENTIUM with 64 data bus. The Pentium was similar to the 80386 and 80486 microprocessor. The two introductory versions of the Pentium operated with a clock frequency of 60 MHz and 66 MHz and a speed of 110 MIPS (Million Instructions Per Second). With better and more advanced technologies, the speed of µPs has increased tremendously. The old 8085 of 1977 executed 0.5 million instruction/sec. (0.5 MIPS), while the 80486 executes 54 million instruction per sec.

The Pentium Pro Processor is the Sixth generation microprocessor introduced in 1995 having better architecture but more in size. The Pentium Pro Microprocessor contains 21 million transistors, 3 integer units as well as a floating unit to increase the performance of most software. The basic clock frequency is 150 MHz and 166 MHz.

1.3 BASIC MICROPROCESSOR SYSTEM

The Microprocessor alone does not serve any useful purpose unless it is supported by memory and I/O ports. The combination of memory and I/O ports with microprocessor is known as microprocessor based system. As discussed above the microprocessor which is the central processing unit executes the program stored in the memory and transfer data to and from the outside world through I/O ports. The microprocessor is interconnected with memory and I/O ports by the data bus, the Address bus and the control bus.

A bus is basically a communication link between the processing unit and the peripheral devices as shown in figure 1.2.

1.3.1 Address Bus

The address bus is unidirectional and is to be used by the CPU to send out address of the memory location to be accessed. It is also used by the CPU to select a particular input or output port. It may consist of 8, 12, 16, 20 or even more number of parallel lines. Number of bits in the address bus determines the minimum number of bytes of data in the memory that can be accessed. A 16-bit address bus for instance can access 2^{16} bytes of data. It is labeled as A_0……A_{n-1}, where **n** is the width of bits of the address bus.

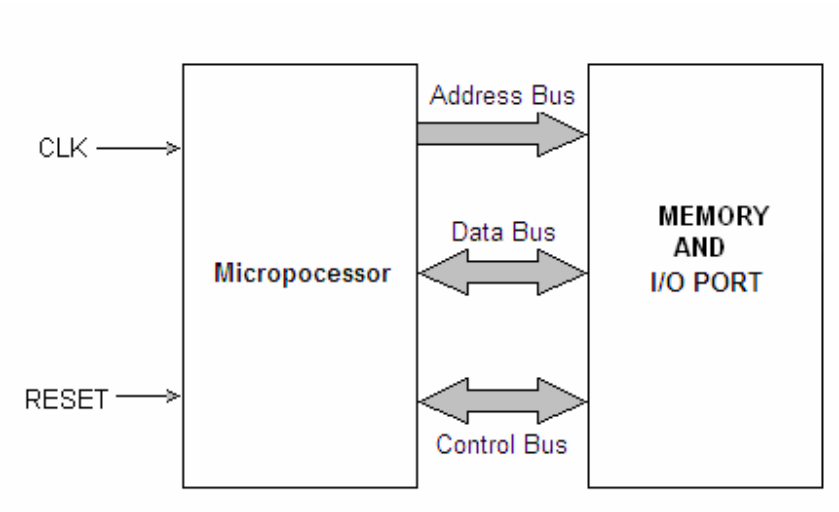

Fig. 1.2

1.3.2 Data Bus

Data bus is bidirectional, that is, data flow occurs both to and from CPU and peripherals. There is an internal data bus which may not be of the same width as the external data bus by that connects the I/O and memory. A microprocessor is characterized by the width of its data bus. All those microprocessors having internal and external data buses of different widths are characterized either by their internal or external data buses. The size of the internal data bus determines the largest number that can be processed by a microprocessor, for instance, having a 16-bit internal data bus is 65536 (64K). The bus is labeled as: D_0 ……$D_{n-1,}$ where n is the data bus width in bits

1.3.3 Control Bus

Control bus contains a number of individual lines carrying synchronizing signals. The control bus sends out control signal to memory, I/O ports and other peripheral devices to ensure proper operation. It carries control signals like MEMORY READ, MEMORY WRITE, READ INPUT PORT, WRITE OUTPUT PORT, HOLD, INTERRUPT etc. For instance, if it is desired to read the contents of a particular memory location, the CPU first sends out address of that very location on the address bus and a 'Memory Read' control signal on the control bus. The memory responds by outputting data stored in the addressed memory location on the data bus.

This book will confine the detailed study of 8085 microprocessor because it is most commonly used microprocessor. However, evolution of microprocessors has been discussed in this chapter, in order to have the knowledge microprocessors introduced so far. Before discussing the details of the 8085, brief discussion of 8-bit microprocessor 8080 is given here.

1.4 BRIEF DESCRIPTION OF 8-BIT MICROPROCESSOR 8080A

Intel 8080 microprocessor is a successor to the Intel 8008 CPU. The Intel 8080/8080A was not object-code compatible with the 8008, but it was source-code compatible with it. The 8080 CPU had the same interrupt processing logic as the 8008, which made porting of old applications easier. Maximum memory size on the Intel 8080 was increased from 16 KB to 64 KB. The number of I/O ports was increased to 256. In addition to all 8008 instructions and addressing modes the 8080 processor included many new instructions and direct addressing mode. The 8080 also included new Stack Pointer (SP) register. The SP was used to specify position of external stack in CPU memory, and the stack could grow as large as the size of memory. Thus, the CPU was no longer limited to 7-level internal stack, like the 8008 did.

The Intel 8080, an 8-bit microprocessor was very popular. Fig. 1.2 shows the shape of the microprocessor and Fig. 1.3 shows the pin out configuration of the 8080A microprocessor. Its salient features include:

a) A two-phase clock input Q1 and Q2
b) 16-bit address bus
c) 8-bit data bus
d) Power supply input of +5V, -5V and +12V required.
e) The 8080A places the status of the operation on the data bus during the earlier part of the cycle and places data on the bus during later part of cycle.

Fig. 1.2

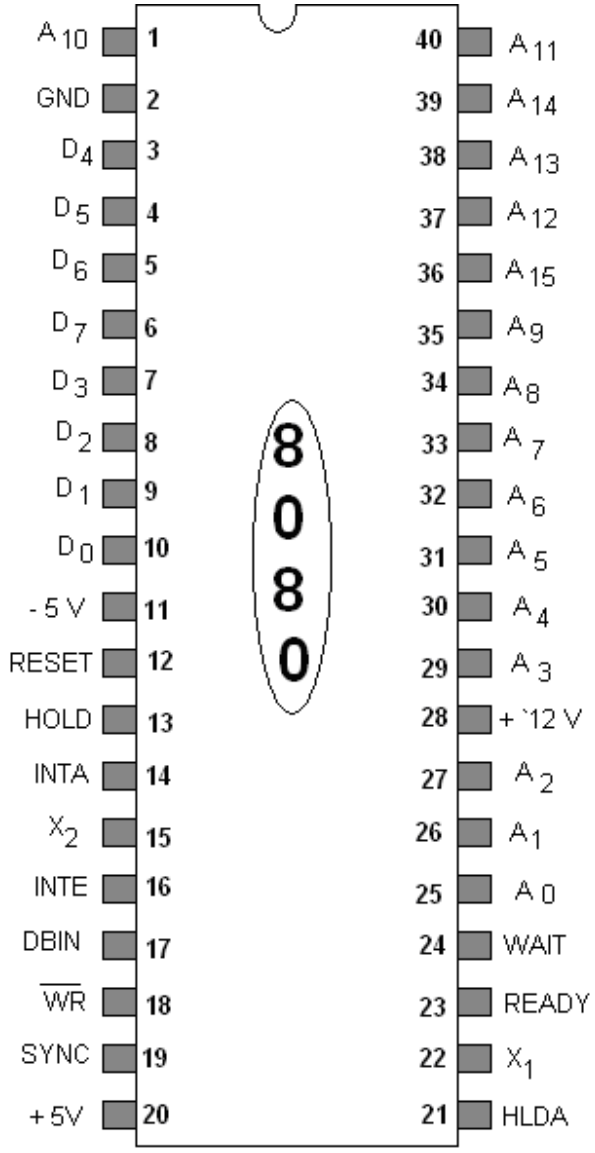

Fig. 1.3

Program memory Pprogram can be located anywhere in memory. Jump, branch and call instructions use 16-bit addresses, i.e. they can be used to jump/branch anywhere within 64 KB. All jump/branch instructions use absolute addressing.

Data memory The processor always uses 16-bit addresses so that data can be placed anywhere.

Stack memory It is limited only by the size of memory. Stack grows downward.

Interrupts The processor supports maskable interrupts. When an interrupt occurs the processor fetches from the bus one instruction, usually one of these instructions:

- One of the 8 RST instructions (RST0 - RST7). The processor saves current program counter into stack and branches to memory location N * 8 (where N is a 3-bit number from 0 to 7 supplied with the RST instruction).
- CALL instruction (3 byte instruction). The processor calls the subroutine, address of which is specified in the second and third bytes of the instruction.

The interrupt can be enabled or disabled using EI (Enable Interrupts) and DI (Disable Interrupts) instructions.

I/O ports

256 Input ports
256 Output ports

Registers

Accumulator or A register is an 8-bit register used for arithmetic, logic, I/O and load/store operations.

Flag is an 8-bit register contains the following five, 1-bit flags:

- Sign flag - set if the most significant bit of the result is set.
- Zero - set if the result is zero.
- Auxiliary carry flag - set if there was a carry out from bit 3 to bit 4 of the result.
- Parity flag - set if the parity (the number of set bits in the result) is even.
- Carry flag - set if there was a carry during addition, or borrow during subtraction/ comparison.

General registers:

- 8-bit B and 8-bit C registers can be used as one 16-bit BC register pair. When used as a pair the C register contains low-order byte. Some instructions may use BC register as a data pointer.
- 8-bit D and 8-bit E registers can be used as one 16-bit DE register pair. When used as a pair the E register contains low-order byte. Some instructions may use DE register as a data pointer.

- 8-bit H and 8-bit L registers can be used as one 16-bit HL register pair. When used as a pair the L register contains low-order byte. HL register usually contains a data pointer used to reference memory addresses.

Stack pointer It is a 16 bit register. This register is always incremented/ decremented by 2.

Program counter It is also a 16-bit register.

Instruction Set

8080 instruction set consists of the following instructions:

- Data moving instructions.
- Arithmetic - add, subtract, increment and decrement.
- Logic - AND, OR, XOR and rotate.
- Control transfer – conditional, unconditional, call subroutine, return from subroutine and restarts.
- Input/Output instructions.
- Other – setting/clearing flag bits, enabling/disabling interrupts, stack operations, etc.

1.5 COMPUTER PROGRAMMING LANGUAGES

In order for computers to accept commands from human and perform tasks vital to productivity, a means of communication must exist. Programming languages provide this necessary link between man and machine. Because they are quite simple compared to human language, rarely containing more than few hundred distinct words, programming languages must contain very specific instructions. There are more than 2,000 different programming languages in existence, although most programs are written in one of several popular languages, like BASIC, COBOL, C++, or Java. Programming languages have different strengths and weaknesses. Depending on the kind of program being written, the computer will run on the experience of the programmer, and the way in which the program will be used, the suitability of one programming language over another will vary. One can categorize computer language as low Level and high level programming languages which are being discussed in the subsequent subsections.

1.5.1 Low-Level Programming Language

A low-level programming language is a language that provides little or no abstraction from a computer's instruction set architecture. The word "low" refers to the small or nonexistent amount of abstraction between the language and machine language; because of this, low-level languages are sometimes described as being "close to the

hardware." A low-level language does not need a compiler or interpreter to run; the processor for which the language was written is able to run the code without using either of these.

By comparison, a high-level programming language isolates the execution semantics of computer architecture from the specification of the program, making the process of developing a program simpler and more understandable.

Low-level programming languages are sometimes divided into two categories: first generation, and second generation programming languages.

First Generation Programming Language

The First-Generation Programming Language (1GL) is machine code or machine language. Machine language is a language which is directly understood by a computer. It is also called binary language as it is based on 0s or 1s. Any instruction in machine language is represented in terms of 0's and 1's, even the memory addresses are given in binary mode. Programs in machine language are very difficult to read and understand as binary codes of each command can not easily be remembered. So it is very difficult and complicated to write the computer program in machine language. The experienced programmer can only work in machine language that too after having the good knowledge of machine hardware. Programs written in machine language cannot easily be understood by other programmers. Currently, programmers almost never write programs directly in machine code, because as discussed above it not only require attention to numerous details which a high-level language would handle automatically, but it also requires memorizing or looking up numerical codes for every instruction that is used.

Second Generation Programming Language

The Second-Generation Programming Language (2GL) is assembly language. Assembly language was first developed in the 1950s and it is different for different microprocessors. It was the first step to improve the computer programming. For writing the programs in assembly language it is necessary that the programmers should have the knowledge of machine hardware. The assembly language eliminated much of the error-prone and time-consuming first-generation programming needed with the earliest computers, freeing the programmer from tedious or boring jobs such as remembering numeric codes and calculating memory addresses. The assembly language was once widely used for all sorts of programming. However, by the 1980s (1990s on small computers), the use of assembly languages had largely been supplanted by high-level languages, in the search for improved programming productivity.

Assembly languages are basically a family of low-level languages for programming computers, microprocessors, microcontrollers etc. They implement a symbolic representation of the numeric machine codes and other constants needed to program a particular CPU architecture. This representation is usually defined by the hardware manufacturer, and is based on abbreviations (called mnemonics) that help the

programmer remember individual instructions, registers, etc. An assembly language is thus specific to certain physical or virtual computer architecture. Instructions (statements) in assembly language are generally very simple, unlike those in high-level languages. Generally, an opcode is a symbolic name for a single executable machine language instruction, and there is at least one opcode mnemonic defined for each machine language instruction. Each instruction typically consists of an *operation* or *opcode* plus zero or more *operands*. Most instructions refer to a single value, or a pair of values. Operands can either be immediate (typically one byte values, coded in the instruction itself) or the addresses of data located elsewhere in storage.

A typical assembly language statement of 8080A or 8085 microprocessor written by the programmer is given below, which is divided in to four fields namely, Label, Mnemonics or Operation code (Opcode), Operand and comments.

Label	**Mnemonics**	**Operand**	**Commnets**
START:	LXI H,	2500 H	; Initialize H-L register pair

A label for an instruction is optional, but it is very essential for specifying jump locations. Similarly, comments are also optional but it is required for good documentation. The four fields of assembly language statements shown above are separated by the following delimiters:

Delimiters	**Placement**
Colon (:)	A colon is placed after the Label. Label is optional.
Space ( )	Space is left between an opcode and operand.
Comma (,)	A comma is placed between two operands.
Semicolon (;)	Semicolon is placed between the comments.

The program written in assembly language is converted to machine language manually. For writing the program in machine language, the starting address, where the program is to be stored should be known. Now the op code of the instruction is to be written in first location (starting address) and in the consecutive memory locations data /address of the operand is written. While storing the address in the memory locations, lower byte of he address is stored first then the upper byte.

A utility program called an assembler is used to translate assembly language statements into the target computer's machine code. The assembler performs a more or less isomorphic translation (a one-to-one mapping) from mnemonic statements into machine instructions and data. The reverse process that is conversion of machine language to the assembly language is done by deassembler.

For software development for a microprocessor/ microcomputer (written in assembly language in large number of instructions), it is absolutely essential to use an assembler. In fact assembler translates mnemonics into binary code with speed and accuracy; thus eliminating human error in looking for the opcodes. Other advantages of using the assembler for the software development are as follows:

- It assigns appropriate values to the symbols used in a program. This facilitates specifying jump locations.
- The assembler checks syntax errors, such as wrong labels and expressions, and provides error messages. However it cannot check logic errors in a program.
- It is easy to insert or delete instructions in a program; the assembler can reassemble the entire program quickly with new memory locations and modified addresses fro jump locations. This avoids rewriting the program manually.

1.5.2 High-Level Programming Language

The machine language and assembly languages discussed above are the first and second generation programming languages which fall in the category of low level languages. These languages require deep knowledge of computer hardware. The high level computer languages developed around 1960s are machine independent i.e. computer hardware is not necessary to know for the programmers. In high level languages one has to know only the instructions in English word and logic of the problem irrespective of the types of computer being used. For the computer programming prepared in high level language, only the use of English alphabets and mathematical systems like +, -, /, * etc. are made. In fact high level language is more close to user and is easy to read and understand. The high level languages are called procedural language and are designed to solve general and specific problems.

The term "high-level language" does not imply that the language is superior to low-level programming languages - in fact high level refers to the higher level of abstraction from machine language. They have no opcodes that can directly compile the language into machine code, unlike low-level assembly language.

In high level languages the words in English are converted into binary language of different microprocessors with the help of a program called **Interpreter** or **Complier**. The compiler or interpreter accepts English like statements as the input called Source code. The source codes are translated into machine language compatible with the microprocessor being used in the machine. The translation in the machine language from the source code is called the object code. Figure 1.4 shows the block diagram for translation of high level language program into machine code. Each microprocessor needs its own compiler or an interpreter for each high level language.

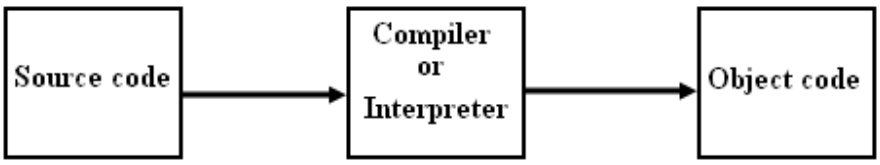

Fig. 1.4

The difference between a compiler and an interpreter is that the compiler reads the entire program first and then generates the object code; where as the interpreter reads one instruction at a time and produces its object code which is executed at the same time before reading the next instruction. The high level programming language developed so far may be categorized into third, fourth and fifth generation programming languages whose brief discussion is given below.

Third Generation Programming Language

A third-generation programming language (3GL) is a refinement of a second-generation programming language. Whereas a second generation language is more aimed to fix logical structure to the language, a third generation language aims to refine the usability of the language in such a way to make it more user friendly. A third generation language improves over a second generation language by having more refinement on the usability of the language itself from the perspective of the user.

Languages like ALGOL, COBOL, FORTRAN IV etc. are examples of this generation and were considered as high level languages. Most of these languages had compilers and the advantage of this was speed. Independence was another factor as these languages were machine independent and could run on different machines. FORTRAN (FORmula TRANslating) and COBOL (COmputer Business Oriented Language) were the first high-level programming languages to make an impact on the field of computer science. Along with assembly language, these two high-level languages have influenced the development of many modern programming languages, including Java, C++, and BASIC.

FORTRAN is well suited for math, science, and engineering programs because of its ability to perform numeric computations. The language was developed in New York by IBM's John Backus. FORTRAN was known as user’s friendly, because it was easy to learn in a short period of time and required no previous computer knowledge. It eliminated the need for engineers, scientists, and other users to rely on assembly programmers in order to communicate with computers. Although FORTRAN is often referred to as a language of the past, computer science students were still taught the language in the early 2000s for historical reasons, and because FORTRAN code still exists in some applications.

COBOL was another high level and third generation programming language well suited for creating business applications. COBOL's strength is in processing data, and in its simplicity.

Other languages like BASIC, C, C++, C#, Pascal, and Java are also third-generation languages.

Fourth-Generation Programming Language

A fourth-generation programming languages (4GL) (1970s-1990) are the programming language designed with a specific purpose in mind, such as the development of commercial business software. In the evolution of computing, the fourth generation language followed the third generation language in an upward trend toward higher abstraction and statement power. The fourth generation language was followed by efforts to define and use a fifth generation language (5GL). Basically the fourth generation languages are languages that consist of statements similar to statements in a human language. Fourth generation languages are commonly used in database programming and scripts. The commonly used fourth generation languages are FoxPro , SQL , MATLAB etc.

Fifth-Generation Programming Language

A fifth-generation programming language (5GL) is a programming language based around solving problems using constraints given to the program, rather than using an algorithm written by a programmer. Most constraint-based and logic programming languages and some declarative languages are fifth-generation languages.

While fourth-generation programming languages are designed to build specific programs, fifth-generation languages are designed to make the computer solve a given problem without the programmer. This way, the programmer only needs to worry about what problems need to be solved and what conditions need to be met, without worrying about how to implement a routine or algorithm to solve them. Fifth-generation languages are used mainly in artificial intelligence research. Prolog, OPS5, Visual Basic, and Mercury etc. are examples of fifth-generation languages.

Problems

1.1 Draw the block diagram of a general computer and discuss in detail the five blocks of a digital computer.
1.2 Discuss History and Evolution of Microprocessor.
1.3 What is microprocessor? What is the difference between a microprocessor and a microcomputer?
1.4 What is the difference between the 4-bit microprocessor and 8-bit microprocessor?
1.5 Name the main 8-bit microprocessors. Give the brief description of 8-bit microprocessor 8080A.

1.6 Discuss basic microprocessor system with the help of block diagram.
1.7 What are low level computer programming languages? Discuss them.
1.8 Discuss first generation computer programming languages.
1.9 Discuss second generation computer programming languages.
1.10 Write short note on high level computer programming languages.
1.11 What is the difference between assembly language and machine language?
1.12 Mention the brief description of Assembly Language. What are the advantages of assembler?

_____

2

SAP – I

For the beginners it is very difficult to understand the operation of a digital computer as it contains large details. To understand the step by step operation of a digital computer, the concept of Simple as Possible (SAP) computer has been introduced. Simple as possible computer, a conceptual computer will be discussed in three stages namely SAP – I, SAP – II and SAP – III computers. All the necessary details for the operation of digital computers will be discussed in three stages. After the study of these three stages of SAP computers, we will be in a position to understand clearly the fundamentals of microprocessor 8085 including the architecture, programming and interfacing devices. In this chapter the organization, programming and circuits of SAP – I computer will be discussed; the succeeding chapters will have the details of other stages of SAP computers.

2.1 ARCHITECTURE OF SAP - I

SAP – I, a conceptual computer is an 8-bit computer, as it can process the data of 8-bits. Further it is a simple computer and is considered for the basic understanding of the operation of digital computers, so it is assumed that it can store only 16 words (each word being 8 bit long). The length of the memory address register will of 4 bits since $2^4 = 16$ (16 is the total capacity of the memory unit). The address of 16 memory locations of memory address register (MAR) will be 0000 to 1111 i.e.

Memory locations (in Hexadecimal)	Address	Memory locations (in Hexadecimal)	Address
0 H	0000	8 H	1000
1 H	0001	9 H	1001
2 H	0010	A H	1010
3 H	0011	B H	1011
4 H	0100	C H	1100
5 H	0101	D H	1101
6 H	0110	E H	1110
7 H	0111	F H	1111

The basic architecture of this computer is shown in figure 2.1. It contains an 8-bit W-Bus (Wire Bus), which is used for data transfer to various 8-bit registers. A Bus is a group of conducting wires. In this figure, all register outputs connected to W-Bus are three-state which allows ordinary transfer of data. Remaining other register outputs continuously drive the boxes they are connected to.

A brief discussion of each block is given below:

Program Counter

First block of the SAP –I computers is the Program Counter (PC). It is basically the part of the control unit, its function is to send to the memory the address of the next instruction to be fetched and executed. Program counter is also called as the pointer as it is like someone pointing a finger at a list of instructions, saying do this first and do this next and so on.

In the beginning, program and data is stored in the memory through the input unit. A 4-bit binary address (0000 to 1111) is sufficient to address a word in the memory. The first instruction of the program is stored in the memory location 0000, second instruction at 0001 location, and the third instruction at 0010 location and so on. When the computer starts executing the program, the program counter is reset. The program counter is then incremented by one to get the next address of the memory location. After the first instruction is fetched and executed, the PC sends address 0001 to memory. Again the PC is incremented by one. After execution of second instruction, PC sends the next address to memory and so on.

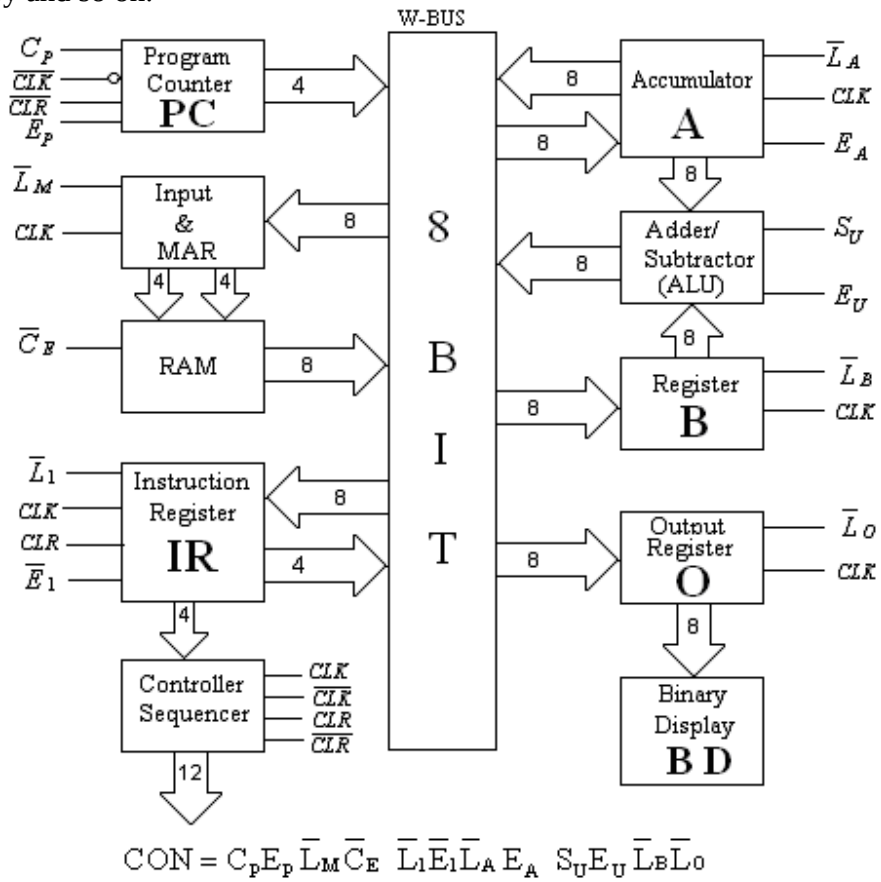

Fig. 2.1

Input and MAR

The second block of SAP –I computer is Input and Memory Address Register (MAR). It includes 4 bit address register and 8 bit data register. These registers are basically the parts of input unit. The input and MAR sends 4 bit address and 8 bit data to memory unit, this unit helps in storing the instructions and data to the memory, before the computer run starts. This unit includes a matrix of switches (micro-switches) for address

and data. In this SAP-I computer, the switch matrix allows to send 4 address bits and 8 data bits to memory. The relevant switch is opened or closed to program the memory. This can be done by providing switches on the front panel of the computer.

The memory address register is also the part of SAP-I memory. When SAP-I computer starts executing the program, the address in the PC is latched into the MAR. The MAR will then send this address to RAM for the read operation.

Memory Unit

It is 16x8 static TTL RAM (Random Access Memory) i.e. it is capable of storing 16 words (total capacity is only of 16 words) and each word is of 8 bit long. It stores the program and data before the execution of program; and during the execution it sends the stored instruction and data to the W-bus for further transfer to other registers as soon as address is received by it from MAR.

Instruction Register

The instruction register of SAP-I computer is the part of control unit. As already discussed during the execution of program, the content of addressed memory location is placed on the W-Bus. At the same time, during the next positive edge of the clock pulse this instruction (content of memory location) is loaded into the Instruction Register. The instruction register now splits the content of the instruction (8-bit) into two nibbles (one nibble is of 4-bit long). Instruction register sends the upper nibble directly to Controller/Sequencer, the lower nibble is, however, placed by the Instruction register to W-Bus for the read operation whenever needed.

Controller Sequencer

The block controller sequencer is basically control unit. This is a key unit for the automatic operation of this SAP-I computer. It generates a control word of 12 bits as given below:

$$CON = C_P E_P \overline{L}_M \overline{C}_E \ \overline{L}_1 \overline{E}_1 \overline{L}_A E_A \ S_U E_U \overline{L}_B \overline{L}_O$$

The symbolic notations of the control signal (CON) used in the computer are given in table 2.1.

Table 2.1

Notation	Interpretation
C_P	PC is incremented, when C_P is high.
E_P	Enable PC, when E_P is high.
$\overline{L}_M$	Loads MAR from W-Bus, when $\overline{L}_M$ is low.
$\overline{C}_E$	Loads RAM, when $\overline{C}_E$ is low.
$\overline{L}_1$	Loads instruction register, when it is low.
$\overline{E}_1$	Enable instruction register, when it is low.

$\overline{L}_A$	Loads the accumulator, when it is low.
E_A	Enable the accumulator, when it is high.
S_U	Enables subtraction, when if is high and enables addition when it is low.
E_U	Enable Adder/Subtrator to send the answer to W-Bus, when it is high.
$\overline{L}_B$	Loads the register B, when it is low.
$\overline{L}_O$	Loads the output register, when it is low.

Accumulator

The accumulator or register A is an 8-bit register and it is also called the buffer register. When $\overline{L}_A$ is low, the data from the W-Bus is loaded to the accumulator at the positive edge of the clock pulse. This data also directly goes to the Adder/Subtractor. The answer of Adder/Subtractor may also be loaded to the accumulator via W-Bus. The answer or the data stored in Accumulator will go to W-Bus when E_A is high.

Adder-Subtractor

The adder-Subtractor is the part of Arithmetic and Logical Unit (ALU) of the computer. This block can add the content of B-register to accumulator content when S_U is low. Similarly, this block can subtract the content of B-register from the accumulator content when S_U is high. The answer of addition or subtraction may be loaded to W-Bus when E_U is high. The subtraction in the block adder/subtrator is done using 2's complement method.

Register B

The register B is the part of Arithmetic and Logical Unit (ALU) of the computer. It is another buffer register of 8 bit long. The content to be added to the accumulator or subtracted from the accumulator, is loaded to B-register from W-Bus when $\overline{L}_B$ is low.

Output Register O

The output register **O** is the part of the output unit of the SAP-I computer. At the end of the execution of program the answer available at the accumulator may be transferred to output register **O**, at the positive edge of the clock pulse and when $\overline{L}_O$ is low, this register is also called the output port.

Binary Display (BD)

The last block of SAP-I computer is Binary Display (BD), which is the part of output unit. This display unit contains 8 LEDs (Light Emitting Diodes) connected to 8 bit output port through 8 flip-flops. When the data or answer is available at the output port, the same is transferred to LEDs indicating the answer is in binary form.

2.2 INSTRUCTION SET OF SAP-I COMPUTER

The instruction set is a set of instructions that can be executed by the computer. The computer programming is done using these instructions. Any problem to be solved on the computer is to be written in the form of a program. The SAP-I computer has got only five instructions as it is a very simple computer. These instructions are given in table 2.2. The instructions are written in abbreviated form or short form. These short forms of the instructions are known as Mnemonics (Memory aids). In fact the instructions in short form can easily be remembered by the programmers or users. Further, every instruction is stored in computer in coded form known as Op Code (Operation Code). The Op codes for the instructions of SAP-I computer given in table 2.2 are shown in binary form. From the above discussion it is clear that mnemonics is the short form of instruction for the user's remembrance and op code is the coded form of the instruction in machine language.

Table 2.2

Mnemonic	Op Code (Binary)	Operation
LDA	0000	It loads the accumulator the content from addressed location.
ADD	0001	It adds the content of the memory location to the accumulator content.
SUB	0010	It subtracts the content of the memory location from the accumulator content.
OUT	1110	It transfers the accumulator content to the output port.
HLT	1111	It stops the computer for further execution.

LDA Instruction

The LDA instruction loads the content from the specified memory location to the accumulator. There is always an operand with this instruction. The operand with the LDA instruction is the address of the memory location whose content is to be transferred to the accumulator.

For example

LDA 9 H

will load the accumulator, the content from the memory location 9 H. The alphabet H denotes hexadecimal number, as the op code for LDA is 0000 and binary equivalent of 9H is 1001. The machine language for this instruction is

0000 1001.

It must be remembered that LDA 9 H is known as the assembly language of the instruction and 0000 1001 (09H) is known as machine language of the instruction.

If the memory location 9H has the content 0001 0010 (12 H), then after execution of the instruction in SAP-I computer, it will load the content 0001 0010 to the accumulator, i.e. $A \leftarrow 00010010$ or $A \leftarrow 12H$

ADD Instruction

ADD instruction adds the content of memory location to the accumulator content. The address of the memory location is the operand of this instruction.

For example

ADD E H

adds the content of memory location E H (1110) to the accumulator content.

If before the execution of this instruction accumulator A is having data say 00010101, and 0000 0001 is already stored in memory location E H, then after execution of he instruction ADD E H the accumulator is loaded with the data 0001 0110,

as 0000 10101 + 0000 0001 = 0001 0110.

i.e. $A \leftarrow 00010110$ or $A \leftarrow 16H$

SUB Instruction

SUB instruction subtracts the content of the memory location from the accumulator content. The operand for this instruction is the address of the memory location.

For example

SUB C H

subtracts the content of memory location C H (1100) from the accumulator content.

If before the execution of this instruction accumulator A is having the content say 0000 0011 and the content in memory location C H is 0000 0010, then after the execution of this instruction, the accumulator A will have the answer as:

0000 0011 – 0000 0010 = 0000 0001

So $A \leftarrow 00000001$ or $A \leftarrow 01H$

OUT Instruction

The SAP-I instructions LDA, ADD and SUB discussed above are the memory reference instructions since the address of the memory location is the operand for these instructions. OUT instruction is not the memory reference instruction, as this instruction is itself complete and operand is not needed. The OUT instruction is used to transfer the accumulator content (answer after processing) to the output port.

HLT Instruction

HLT instruction is also not memory reference instruction, as it is complete itself and no operand is used with this instruction. HLT instruction stops further processing of the computer. This instruction must be used as the last instruction of every program otherwise meaningless answer will be obtained.

The complete assembly and machine code (Binary and Hexadecimal) of all the operations are shown in table 2.3.

Table 2.3

Assembly Code	Machine Code		Operations
	Binary	Hex	
LDA 5H	0000 0101	05 H	Loads the Acc., the content of memory location 5 H.
ADD CH	0001 1100	1C H	Adds the content of memory location CH to Acc. content.
SUB BH	0010 1011	2B H	Subtracts the content of memory location BH from the Acc. content.
OUT	1110 xxxx	Ex H	Sends Acc. content to the output port.
HLT	1111 xxxx	Fx H	Stops the processing.

2.3 PROGRAMMING OF SAP-I COMPUTER

Programming means set of instructions written by the user or programmer for performing a particular task. These instructions are then fed to the computer to get the

desired result. The program for the particular task is written by the programmer in assembly language (in mnemonic form) and then fed to the computer in the consecutive memory locations in the form of op codes (machine language) along with data. The program written in mnemonics form or assembly language is also called Source Program and the program written in machine language is known as Object Program. It will now be illustrated in more detail by taking an example.

Suppose we wish to get the addition of three numbers (decimal) 2, 3 and 5. Let these numbers are stored in three different memory locations 6, 7 and 8 respectively. Following steps will be taken for its execution:

Step-I	First number from the memory location 6 should be transferred to the accumulator (LDA 6 H).
Step-II	Second number from memory location 7 should be added to the accumulator and sum of these two numbers should remain in the accumulator (ADD 7 H).
Step-III	Third number from memory location 8 should now be added to the accumulator content and final sum should also remain in the accumulator (ADD 8 H).
Step-IV	Final answer (accumulator content) should be sent to the output port for the display in binary form (OUT).
Step-V	Stop the processing of the computer (HLT).

The program is now fed in the memory locations starting at 0 H and data in the memory locations starting at 6 H, as:

Memory location (in Hex)	**Mnemonic**
0 H	LDA 6 H
1 H	ADD 7 H
2 H	ADD 8 H
3 H	OUT
4 H	HLT
5 H	xx H
6 H	02 H
7 H	03 H
8 H	05 H

This program in machine language is given as:

Memory location	**Op code**
0000	0000 0110
0001	0001 0111
0010	0001 1000
0011	1110 xxxx
0100	1111 xxxx
0101	xxxx xxxx
0110	0000 0010

0111	0000 0011
1000	0000 0101

Note: x – sign represents any binary digit 0 or 1.

Example 2.1 *Write an assembly language program that performs the following operation in SAP-I computer.*

$$7 + 6 - 4 + 5 - 3$$

Use memory locations 7H to BH for the data. Further convert this program in machine language.

Solution. SAP-I assembly language program of the given problem is as given below:

Memory location (in Hex)	**Mnemonic**
0 H	LDA 7 H
1 H	ADD 8 H
2 H	SUB 9 H
3 H	ADD A H
4 H	SUB B H
5 H	OUT
6 H	HLT
7 H	07 H
8 H	06 H
9 H	04 H
A H	05 H
B H	03 H

This program in machine language is given by:

Memory location	**Op code**
0000	0000 0111
0001	0001 1000
0010	0010 1001
0011	0001 1010
0100	0010 1011
0101	1110 xxxx
0110	1111 xxxx
0111	0000 0111
1000	0000 0110
1001	0000 0100
1010	0000 0101
1011	0000 0011

Example 2.2 *Write an assembly language program to calculate the following expression on SAP-I computer:*

$$Y + 2Z - 3W$$

The data Y, Z and W (as 6, 7 and 2) are stored in memory locations 8H to AH.

Solution.

SAP-I assembly language program of the given problem is as given below:

Memory location (in Hex)	Mnemonic
0 H	LDA 8 H
1 H	ADD 9 H
2 H	ADD 9 H
3 H	SUB A H
4 H	SUB A H
5 H	SUB A H
6 H	OUT
7 H	HLT
8 H	06 H
9 H	05 H
A H	02 H

Example 2.3 *Write assembly program for SAP-I computer to solve the following problem:*

$$17 + 22 + 20 - 33.$$

The numbers are given in decimal. Also give the machine language program.

Solution.

First the decimal numbers are converted to Hexadecimal numbers. The Hexadecimal equivalents of these numbers are given as:

17 = 11 H
22 = 16 H
20 = 14 H
33 = 21 H

Let us assume that these numbers are stored in memory locations 7H to AH.

Memory location (in Hex)	Mnemonic
0 H	LDA 7 H
1 H	ADD 8 H
2 H	ADD 9 H
3 H	SUB A H
4 H	OUT
5 H	HLT
6 H	x x H
7 H	11 H
8 H	16 H
9 H	14 H
A H	21 H

The machine language program is given as follows:

Memory location	Op code
0000	0000 0111
0001	0001 1000
0010	0001 1001
0011	0010 1010
0100	1110 xxxx

0101	1111 xxxx
0110	xxxx xxxx
0111	0001 0001
1000	0001 0110
1001	0001 0100
1010	0010 0001

2.4 WORKING OF SAP-I COMPUTER

For the working of SAP-I computer, instructions are fetched from RAM and then executed one by one in a sequence till a Halt instruction is executed. The SAP-I computer executes program starting from 0 H memory location. For this controller / sequencer unit generates a CLK signal for all the register and CLR signal for the Program counter. As soon as the computer starts executing the program, program counter receives a CLR signal which resets the program counter. The program counter will send the address of 0 H memory location.

In SAP-I computer the loading of a register takes place only when setup and hold times of the clock pulse are satisfied. For this 50% duty cycle clock pulse is used and positive edge occurs half way through each state. Waiting half a cycle before loading the register satisfies setup time; waiting half a cycle after loading satisfies the hold time. Secondly, the reason for waiting half a cycle before loading a register is that when enable input of the sending register goes active, the content of the register suddenly dumped on to register. Stray capacitance and lead inductance may, however, prevent the voltage level immediately. In other words the transients on the W-Bus will be eliminated if the clock has the wait time to die out the transients and valid data is transferred. The control word generated by the controller sequencer unit does the automatic operation of the computer. The execution of a program is carried out by fetching and execution operations of the instructions.

The instruction cycle for the execution of an instruction consists of the following two cycles:

(i) Fetch cycle — fetches a word from memory
(ii) Execution cycle — executes the fetched instruction

We will now discuss these cycles in detail.

2.4.1 Fetch Cycle

The operation of fetch cycle is performed in three states namely:

(a) Address State
(b) Increment State
(c) Memory State

During the address state, the content of PC is transferred to MAR via W-Bus:

$$MAR \leftarrow PC$$

During the increment state, the PC gets incremented. The incremented content will be sent to MAR when next fetch cycle occurs.

$$PC \leftarrow PC+1$$

During the memory state, memory read operation is performed.

$$W-Bus \leftarrow M_{PC}$$

The control word generated by the controller sequencer for these three states is given below:

	C_P	E_P	$\overline{L}_M$	$\overline{C}_E$	$\overline{L}_1$	$\overline{E}_1$	$\overline{L}_A$	E_A	S_U	E_U	$\overline{L}_B$	$\overline{L}_O$	
T_1	0	1	0	1	1	1	1	0	0	0	1	1	**Address State** Only E_P and $\overline{L}_M$ are active. Figure 2.2 shows shaded boxes as active.
T_2	1	0	1	1	1	1	1	0	0	0	1	1	**Increment State** Only C_P is active. Figure 2.3 shows shaded boxes as active.
T_3	0	0	1	0	0	1	1	0	0	0	1	1	**Memory State** Only C_E and $\overline{L}_1$ are active. Figure 2.4 shows shaded boxes as active.

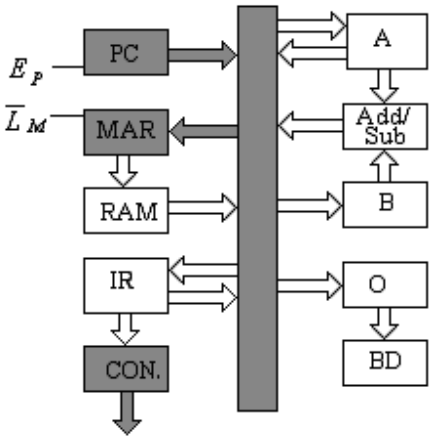

Fig. 2.2

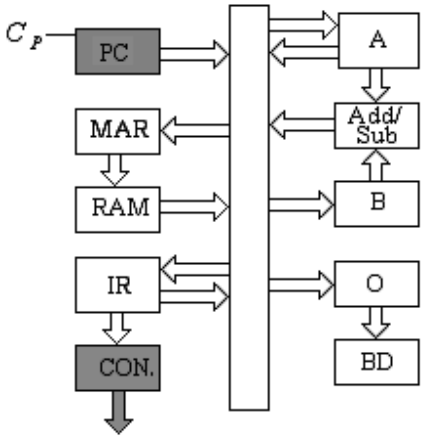

Fig. 2.3

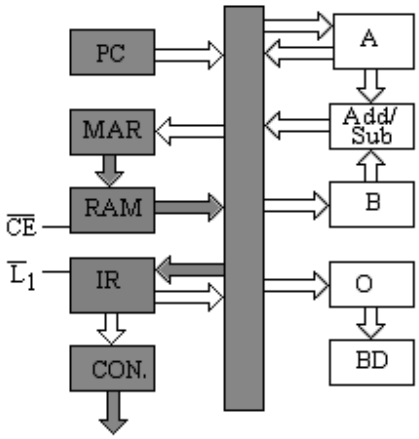

Fig. 2.4

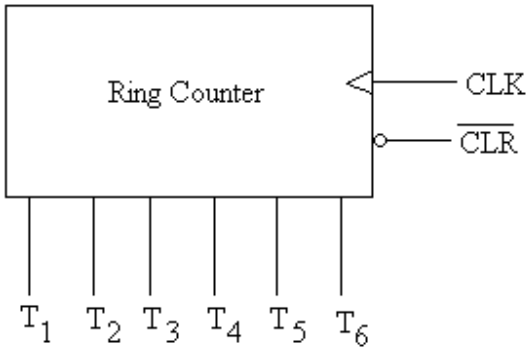

Fig. 2.5(a)

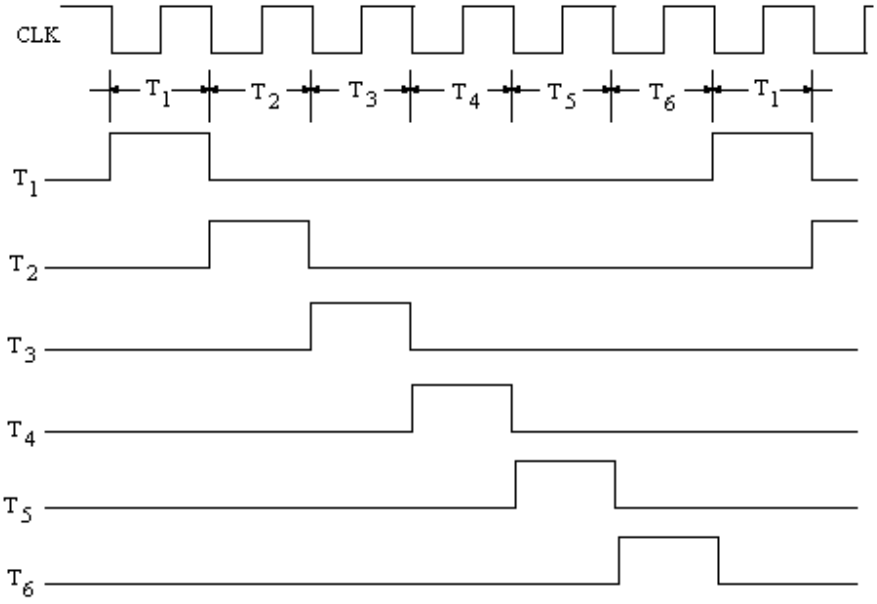

Fig. 2.5(b)

The Controller-sequencer keeps a track of three different states of Fetch cycle and generates control signals accordingly. A ring counter is used for this purpose.

Consider a 6-bit synchronous ring counter as shown in figure 2.5(a). The output T of the ring counter is given by:

$$T = T_6\ T_5\ T_4\ T_3\ T_2\ T_1$$

At the start of the computer run, 6-bit output of the ring counter at the successive clock pulse is shown in figure 2.5(b).

The details of the same are given below:

	T_6	T_5	T_4	T_3	T_2	T_1
1^{st} clock pulse =	0	0	0	0	0	1
2^{nd} clock pulse =	0	0	0	0	1	0
3^{rd} clock pulse =	0	0	0	1	0	0
4^{th} clock pulse =	0	0	1	0	0	0

5^{th} clock pulse = 0 1 0 0 0 0
6^{th} clock pulse = 1 0 0 0 0 0
7^{th} clock pulse = 0 0 0 0 0 1
and so on.

The different outputs are also called T-states or timing states. During first three clock pulses the operation of fetch cycle occurs which are explained below:

During T_1 state of the timing signal, Controller-sequencer generates a signal so that E_P is high and $\overline{L}_M$ is low which sends the content of PC (address of the instruction stored in RAM) to W-Bus and at the positive edge of the clock pulse (midway of the clock pulse) the content of the W-Bus are latched into MAR due to low $\overline{L}_M$ – **This state is called Address State of the fetch cycle.**

During T_2 state of the timing signal, controller sequencer generates a signal giving high to C_P. At the positive edge of the clock pulse (midway of the clock pulse), PC advances the count by 1 – **This state is called Increment State of the fetch cycle.**

During T_3 stat, control signal generated by Controller-sequencer makes $\overline{C}_E$ and $\overline{L}_I$ low. The addressed RAM word is transferred to W-Bus and at positive edge of CLK (midway of clock) the data is transferred to W-Bus and then loaded to Instruction register – **This state is called Memory State of the fetch cycle.**

The next three states of clock pulse are called the execution cycle of SAP-I instructions.

2.4.2 Execution Cycle

After the instruction is fetched and transferred to the Instruction Register (IR) during the fetch cycle, the IR splits the instruction word (8-bit) into two nibbles. The upper nibble goes directly to the controller-sequencer, where it is decoded and accordingly the control word is generated to act as per the direction of the instruction. The decoded output will be different for different instructions (LDA, ADD, SUB, OUT, and HLT). So during the execution cycle (T_4 to T_6 of the clock pulse), the operation of control signal will be different for different instructions. Now we will discuss these operations for each cycle.

Execution Cycle of LDA Instruction:

For the discussion of the operation LDA instruction, let us assume the instruction is LDA 6 H = 0 0 0 0 0 1 1 0

In this instruction 0 0 0 0 is the op code of LDA and 6 H (0 1 1 0) is the address of the location where the data is stored.

During T_3 state of CLK, 0000 0110 is loaded to Instruction Register (IR). The upper nibble 0000 directly goes to controller-sequencer, where it is decoded. During T_4, T_5 and T_6 states for the execution of LDA instruction, the controller-sequencer will generate the following control words in sequence:

	C_P	E_P	$\overline{L}_M$	$\overline{C}_E$	$\overline{L}_I$	$\overline{E}_I$	$\overline{L}_A$	E_A	S_U	E_U	$\overline{L}_B$	$\overline{L}_O$	
T_4	0	0	0	1	1	0	1	0	0	0	1	1	$MAR \leftarrow IR_{LNIBBLE}$
T_5	0	0	1	0	1	1	0	0	0	0	1	1	$A \leftarrow M(MAR)$
T_6	0	0	1	1	1	1	1	0	0	0	1	1	NO OPERATION

During T_4 state of CLK, lower nibble already available at the W-Bus is loaded into MAR since $\overline{E}_I$ and $\overline{L}_M$ are active.

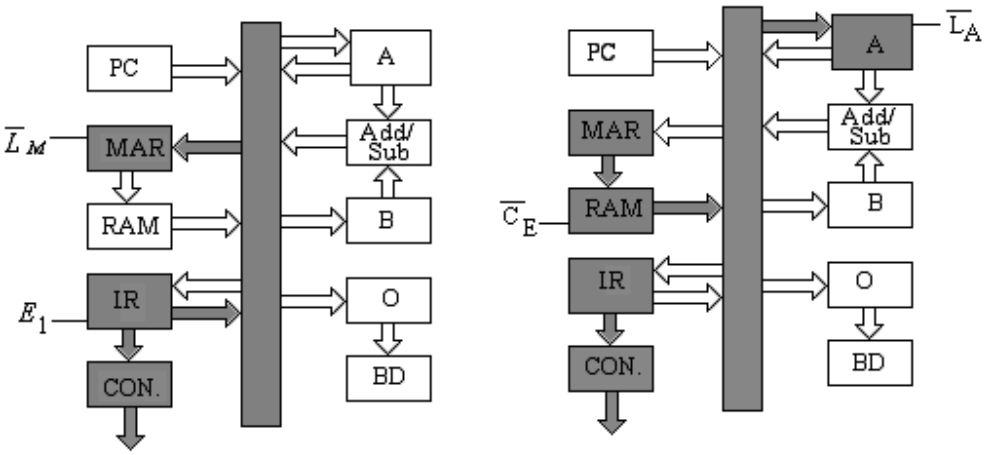
During T_5 state of CLK, $\overline{C}_E$ and $\overline{L}_A$ are active which loads the addressed content from RAM to Accumulator. This was the function of LDA instruction.

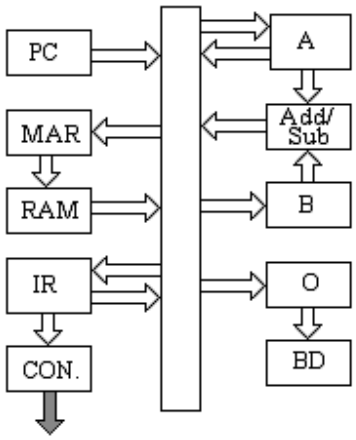
During T_6 state of CLK, no operation is performed as nothing was left for this instruction to do.

T_4 to T_6 states of LDA instruction are shown in figure 2.6 (a to c) with active parts as shaded boxes and figure 2.7 shows timing diagram for Fetch and execution cycle of LDA instruction.

The control word generated for each T-state is called as Microinstruction. One of the instructions in instruction set is known as Macroinstruction. The microinstruction for T_4, T_5 and T_6 states of LDA instruction is given below:

States	Microinstruction	(12 Bit Control Word)
T_4	1A3 H	0001 1010 0011
T_5	2C3 H	0010 1100 0011
T_6	3E3 H	0011 1110 0011





(c)

Fig. 2.6

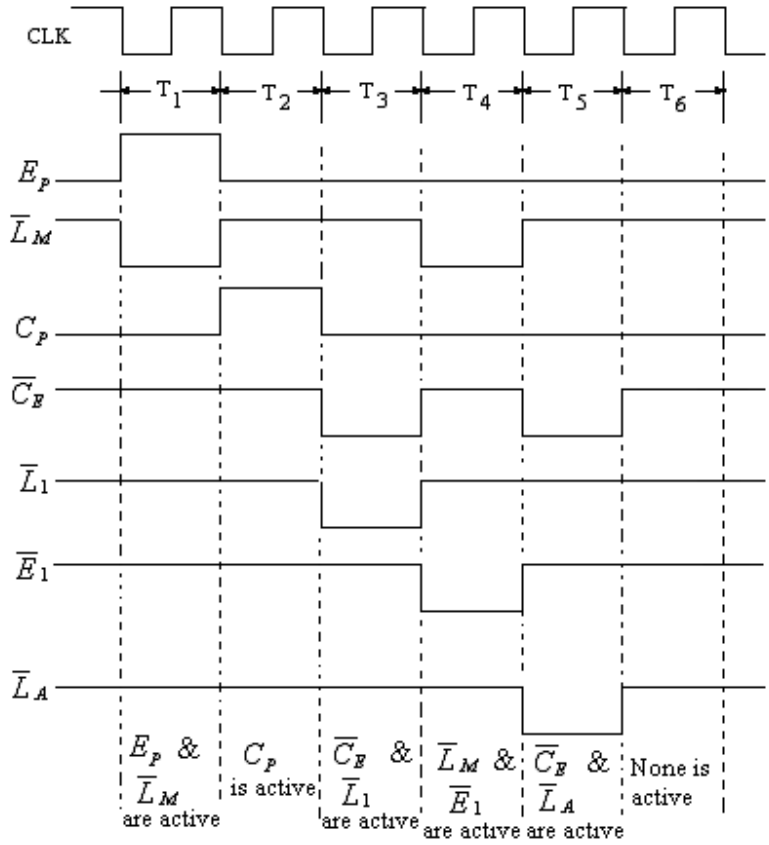


Fig. 2.7

Execution Cycle of ADD Instruction:

For the execution of ADD instruction following control signals in sequence during T_4, T_5 and T_6 states will be observed:

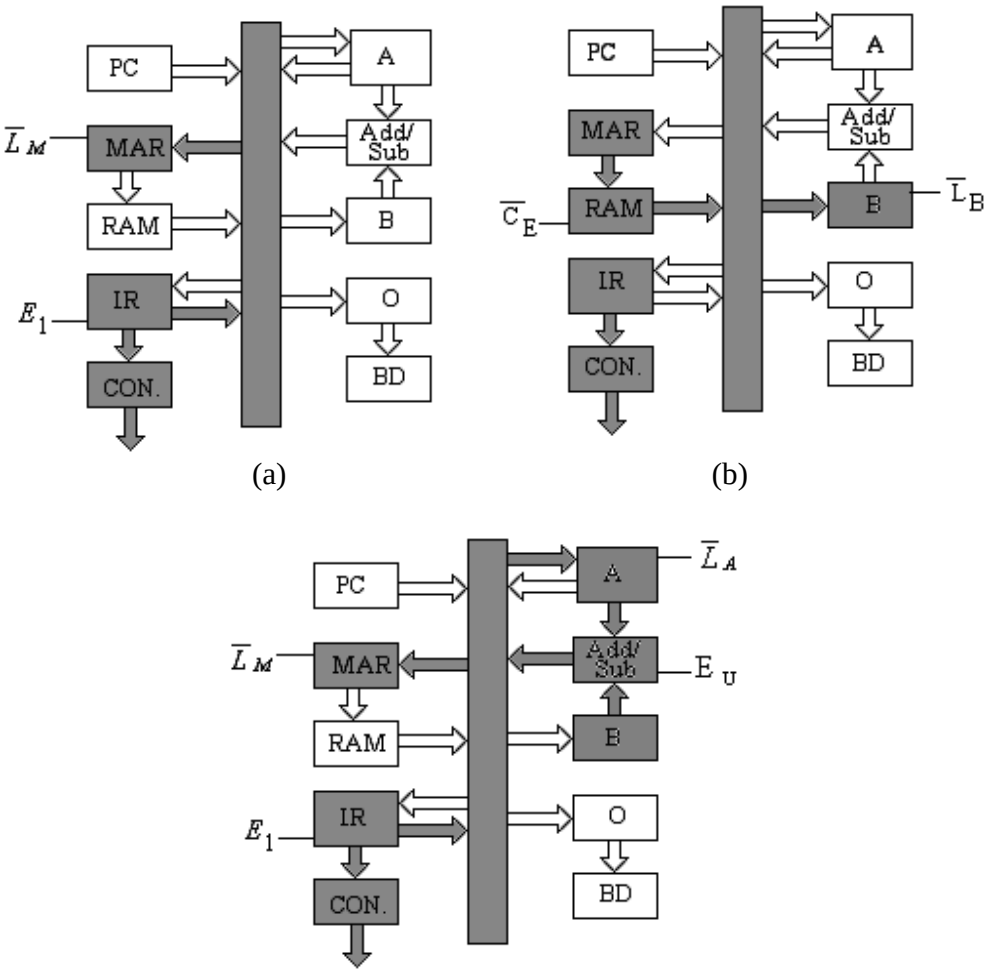
	C_P	E_P	$\overline{L}_M$	$\overline{C}_E$	$\overline{L}_I$	$\overline{E}_I$	$\overline{L}_A$	E_A	S_U	E_U	$\overline{L}_B$	$\overline{L}_O$	
T_4	0	0	0	1	1	0	1	0	0	0	1	1	$MAR \leftarrow IR_{LNIBBLE}$
T_5	0	0	1	0	1	1	1	0	0	0	0	1	$B \leftarrow M(MAR)$
T_6	0	0	1	1	1	1	0	0	0	1	1	1	$A \leftarrow SUM$

During T_4 state, the address part of ADD instruction moves to MAR as $\overline{L}_M$ and $\overline{E}_I$ are active. The data from MAR is fetched and loaded into register B during T_5 state as $\overline{C}_E$ and $\overline{L}_B$ are active. The adder-subtractor adds the content of Accumulator and register B as S_U is inactive. During T_6 state the answer (Sum) is loaded to accumulator, as E_U and $\overline{L}_A$ are active.

T states of ADD instruction are shown in figures 2.8 (a to c) with active parts as shaded boxes. The timing diagram of Fetch and ADD instruction is shown in figure 2.9.

The microinstruction for T_4, T_5 and T_6 states of ADD instruction is given below:

States	Microinstruction	(12 Bit Control Word)
T_4	1A3 H	0001 1010 0011
T_5	2E1 H	0010 1110 0001
T_6	3C7 H	0011 1100 0111



(a) (b)

(c)

Fig. 2.8

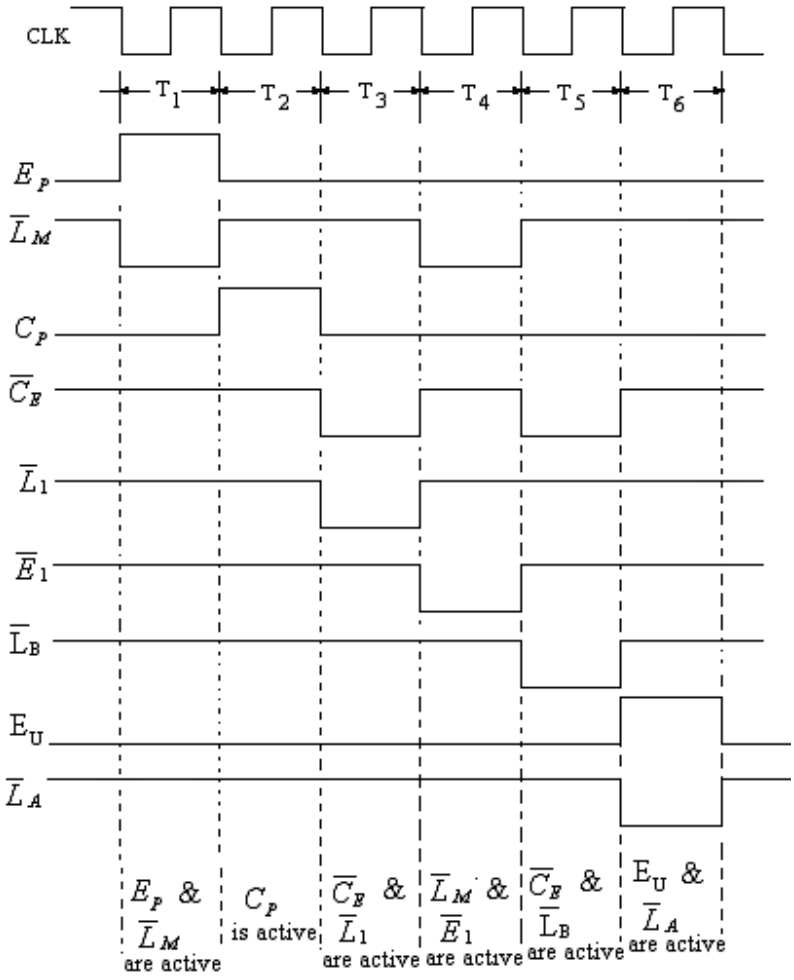


Fig. 2.9

Execution Cycle of SUB Instruction:

The third instruction of SAP-I instruction set is SUB-instruction. For the execution of SUB instruction, following control signals in sequence will be observed during T_4, T_5 and T_6 states.

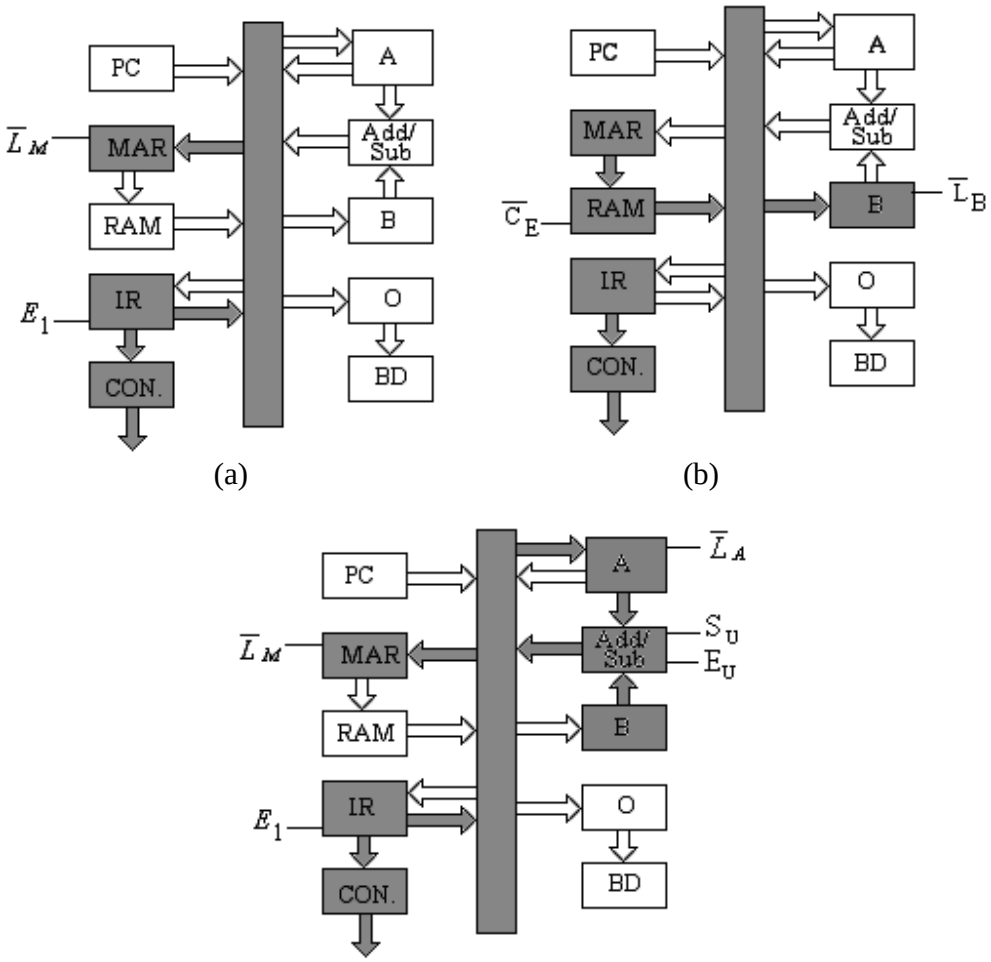
	C_P	E_P	$\overline{L}_M$	$\overline{C}_E$	$\overline{L}_1$	$\overline{E}_1$	$\overline{L}_A$	E_A	S_U	E_U	$\overline{L}_B$	$\overline{L}_O$	
T_4	0	0	0	1	1	0	1	0	0	0	1	1	$MAR \leftarrow IR_{LNIBBLE}$
T_5	0	0	1	0	1	1	1	0	0	0	0	1	$B \leftarrow M(MAR)$
T_6	0	0	1	1	1	1	0	0	1	1	1	1	$A \leftarrow DIFF.$

From the above sequence it is clear that SUB instruction follow the same sequence as ADD instruction except that during T_5 state S_U is high.

T states (T_4 to T_6) of SUB instruction are shown in figures 2.10 (a to c) with active parts as shaded boxes. The timing diagram of Fetch and SUB instruction is shown in figure 2.11.

The microinstruction for T_4, T_5 and T_6 states of SUB instruction is given below:

States	Microinstruction	(12 Bit Control Word)
T_4	1A3 H	0001 1010 0011
T_5	2E1 H	0010 1110 0001
T_6	3CF H	0011 1100 1111



(a) (b)

(c)

Fig. 2.10

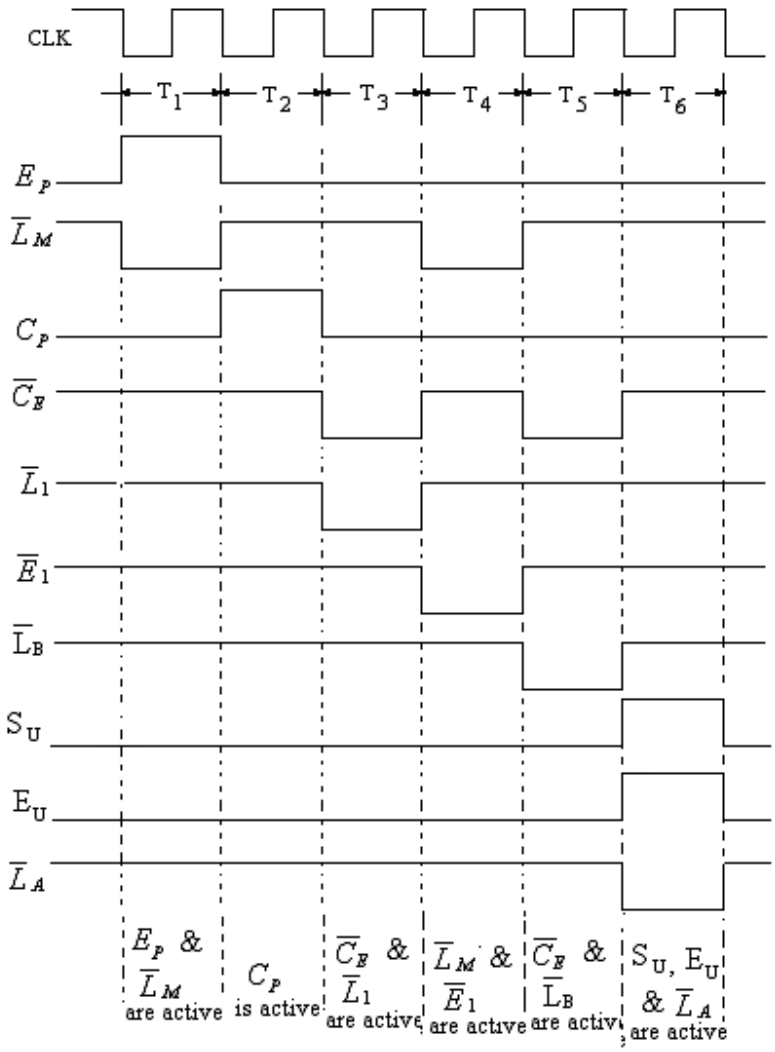


Fig. 2.11

Execution Cycle of OUT Instruction:

For the execution of this instruction, following control signals in sequence will be observed during T_4, T_5 and T_6 states of execution cycle.

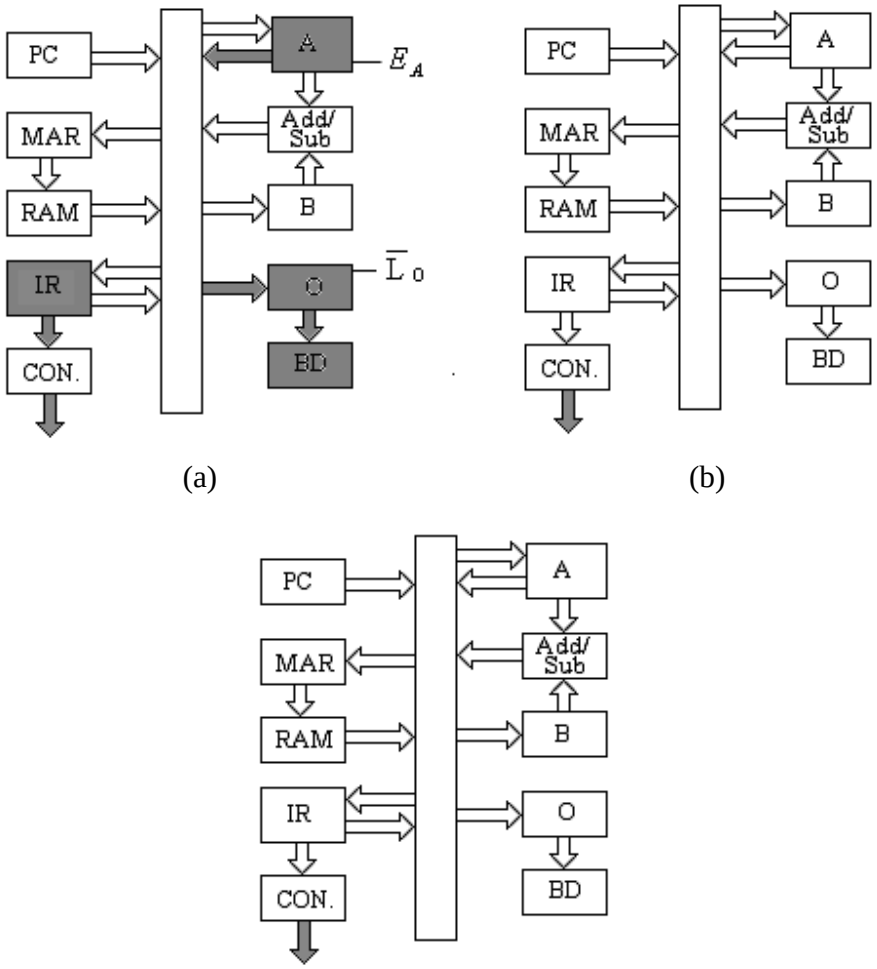
	C_P	E_P	$\overline{L}_M$	$\overline{C}_E$	$\overline{L}_1$	$\overline{E}_1$	$\overline{L}_A$	E_A	S_U	E_U	$\overline{L}_B$	$\overline{L}_O$
T_4	0	0	1	1	1	1	1	1	0	0	1	0
T_5	0	0	1	1	1	1	1	0	0	0	1	1
T_6	0	0	1	1	1	1	1	0	0	0	1	1

During T_4 state, E_A and $\overline{L}_O$ are active due to which at the positive edge of clock pulse accumulator content is loaded to the output register. High E_A send the accumulator data to W-Bus and low $\overline{L}_O$ loads the data from W-Bus to output register. The work of out instruction is complete. So no-operation is performed during T_5 and T_6 state i.e. all the signals of the control word are inactive.

T states of OUT instruction are shown in figures 2.12 (a to c) with active parts as shaded boxes. The timing diagram of Fetch and OUT instruction is shown in figure 2.13.

The microinstruction for T_4, T_5 and T_6 states of OUT instruction is given below:

States	Microinstruction	(12 Bit Control)
T_4	3F2 H	0011 1111 0010
T_5	3E3 H	0011 1110 0011
T_6	3E3 H	0011 1110 0011



(a) (b)

(c)

Fig. 2.12

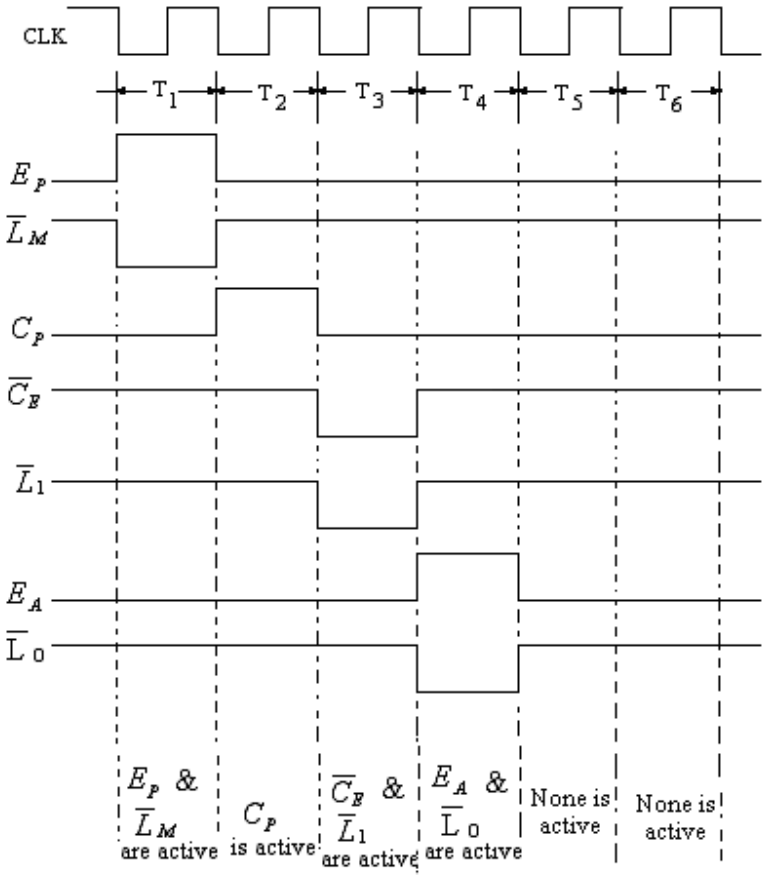


Fig. 2.13

Execution Cycle of HLT Instruction:

HLT instruction does not require any T-cycle for its execution. Thus during T_4, T_5 and T_6 state all the signals of the control word are inactive i.e. no-operation is performed during these states.

	C_P	E_P	$\overline{L}_M$	$\overline{C}_E$	$\overline{L}_I$	$\overline{E}_I$	$\overline{L}_A$	E_A	S_U	E_U	$\overline{L}_B$	$\overline{L}_O$
T_4	0	0	1	1	1	1	1	0	0	0	1	1
T_5	0	0	1	1	1	1	1	0	0	0	1	1
T_6	0	0	1	1	1	1	1	0	0	0	1	1

The microinstruction for T_4, T_5 and T_6 states of HLT instruction is given below:

States	**Microinstruction**	**(12 Bit Control Word)**
T_4	3E3 H	0011 1110 0011
T_5	3E3 H	0011 1110 0011
T_6	3E3 H	0011 1110 0011

Example 2.4 *What are Microinstructions for:*
(i) LDA instruction
(ii) ADD instruction

Solution. (i) During T_4 state of LDA instruction $\overline{L}_M$ and $\overline{E}_I$ are active.
During T_5 state of LDA instruction $\overline{C}_E$ and $\overline{L}_A$ are active
and During T_6 state of LDA instruction None is active.
So Microinstructions for LDA are

For T_4 1A3 H
T_5 2C3 H
T_6 3E3 H

(ii) Similarly, Microinstruction for ADD instruction are

For T_4 1A3 H
T_5 2C3 H
T_6 3E7 H

2.5 HARDWARE DESIGN OF SAP-I COMPUTER

In this section we shall discuss the hardware details of the following blocks of SAP-I computer:

Program Counter
Memory Unit
Instruction Register
Controller-Sequencer
Accumulator
Adder-Sutractor
B-Register
Output Register and Binary Display

2.5.1 Design of Program Counter

The program counter (PC) is designed using four J-K flip-flops. The circuit diagram of program counter is shown in figure 2.14. From this diagram it can well be understood that during the start of computer run a low $\overline{CLR}$ signal resets the program counter to 0 0 0 0. During T_1 state of fetch cycle, a high E_P sends the address to the W-Bus. During T_2 state, high C_P increments the Program counter, at the midway through T_2. the program counter is, however, inactive during T_3 through T_6 states.

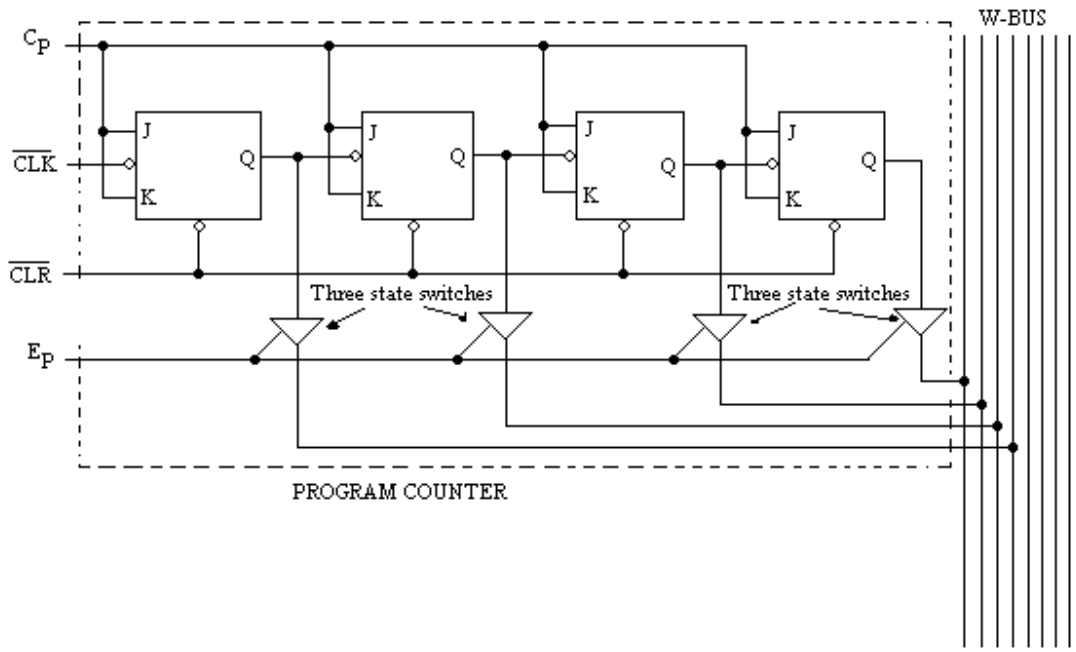

Fig. 2.14

2.5.2 Memory Unit

Figure 2.15 shows the circuit diagram of memory unit, which consists of Input & MAR and RAM. In this figure IC1 and IC2 form Input & MAR; IC3 and IC4 form read/write memory. IC1 is a 4-bit buffer register. It is a three state output register which is configured here in a two state output, as it is not to be connected to W-Bus. IC2 is basically 2 to 1 nibble multiplexer.

When the switch S_1 is connected to Run position, the address bits are directly available at the output of IC2. If on the contrary S_1 is at the Run position, the address bit from the W-Bus will be available at the output of this IC2.

IC3 and IC4 are two 16X4 static RAM, which form the RAM of SAP-I. These two IC's are configured to form, 16X8 read/write memory. When switch S_1 is at PROG position, S_2 is at write position, the data from D_0 to D_7 will be written into static RAM. If S_1 is at Run position, the data already stored in the memory will be available at the W-Bus.

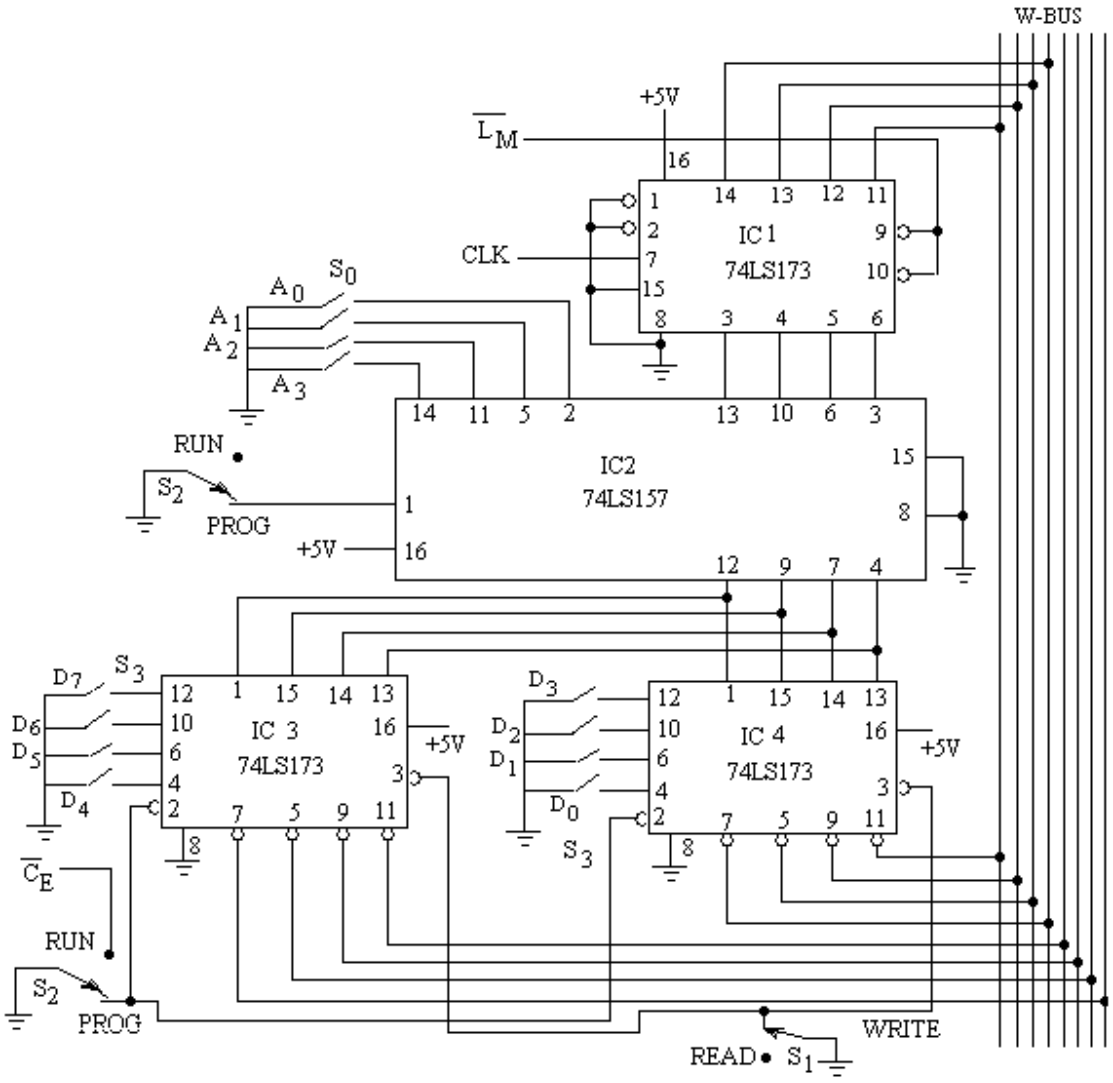

Fig. 2.15

2.5.3 Instruction Register

IC1 and IC2 forms the Instruction Register. These are two four-bit buffer registers. These buffer registers are three state registers. IC1 is configured as two state output. The outputs of this IC are upper nibble I_7 I_6 I_5 I_4 which directly goes to controller-sequencer where these are decoded. The outputs of IC2 are the lower nibble (operand of the fetched instruction), which are directly connected to W-Bus. The logic circuit diagram of the Instruction register is shown in figure 2.16.

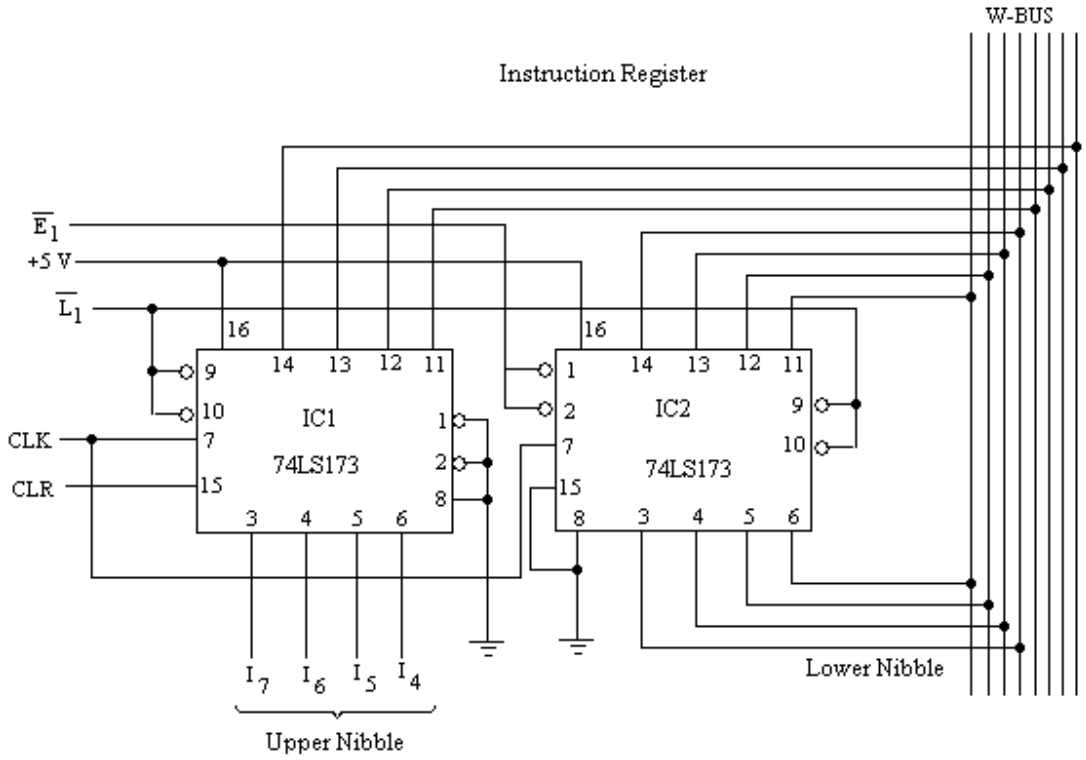

Fig. 2.16

2.5.4 Controller-Sequencer

The schematic block diagram of controller-sequencer is shown in figure 2.17. It consists of a ring counter, instruction decoder and control matrix for the generation of 12-bit control word. The instruction decoder is a simple decoder, which provides the outputs LDA, ADD, Sub, OUT and HLT. In fact it is a 4-to-5 decoder.

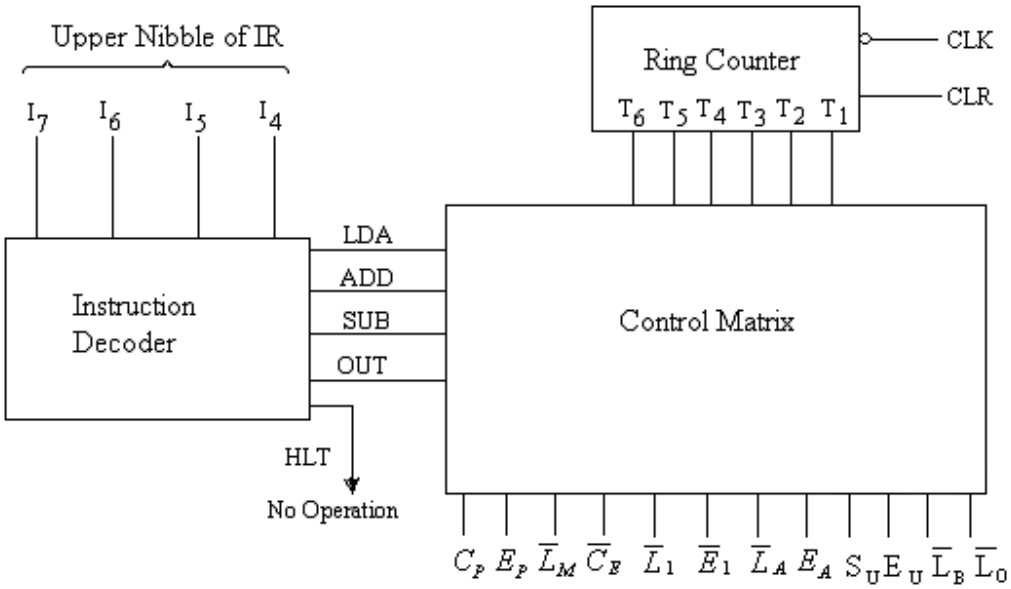

Fig. 2.17

The required logic is shown in table 2.4.

Table 2.4

I_7	I_6	I_5	I_4	OUTPUT
0	0	0	0	LDA
0	0	0	1	ADD
0	0	1	0	SUB
1	1	1	0	OUT
1	1	1	1	HLT

The logic diagram for the Instruction decoder of SAP-I computer is shown in figure 2.18, which is as per the table 2.4.

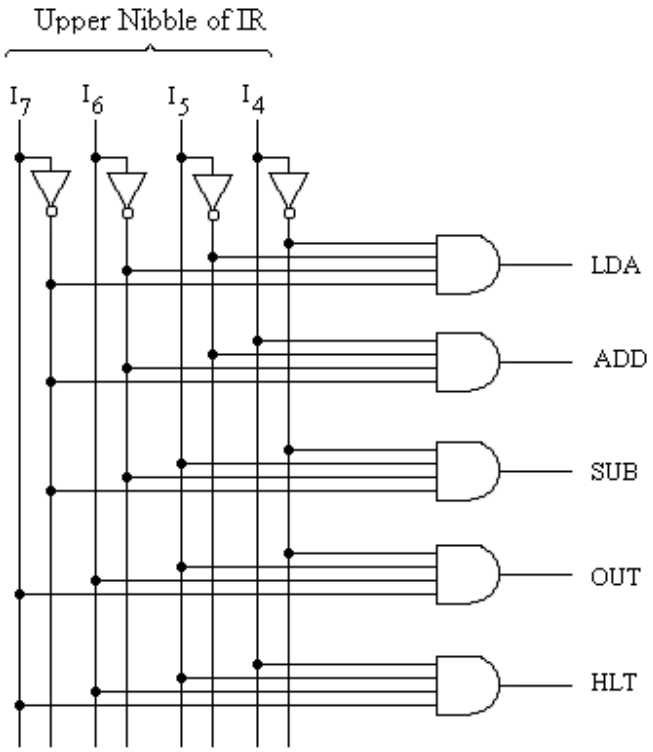

Fig. 2.18

The synchronous counter has already been discussed. This ring counter gives 6-bit output (T_1 to T_6) at the successive clock pulse.

For the generation of 12-bit control signal, the twelve outputs may be obtained from the logic expressions given below:

$C_P = T_2$

$E_P = T_1$

$\overline{L}_M = T_1 + T_4.LDA + T_4.ADD + T_4.SUB$

$\overline{C}_E = T_3 + T_5.LDA + T_5.ADD + T_5.SUB$

$\overline{L}_I = T_3$

$\overline{E}_I = T_4.LDA + T_4.ADD + T_4.SUB$

$\overline{L}_A = T_5.LDA + T_6.ADD + T_6.SUB$

$E_A = T_4.OUT$

$S_U = T_6.SUB$

$E_U = T_6.ADD + T_6.SUB$

$\overline{L}_B = T_5.ADD + T_5.SUB$

$\overline{L}_O = T_4.OUT$

The logic circuit diagram of the above expressions is shown in figure 2.19.

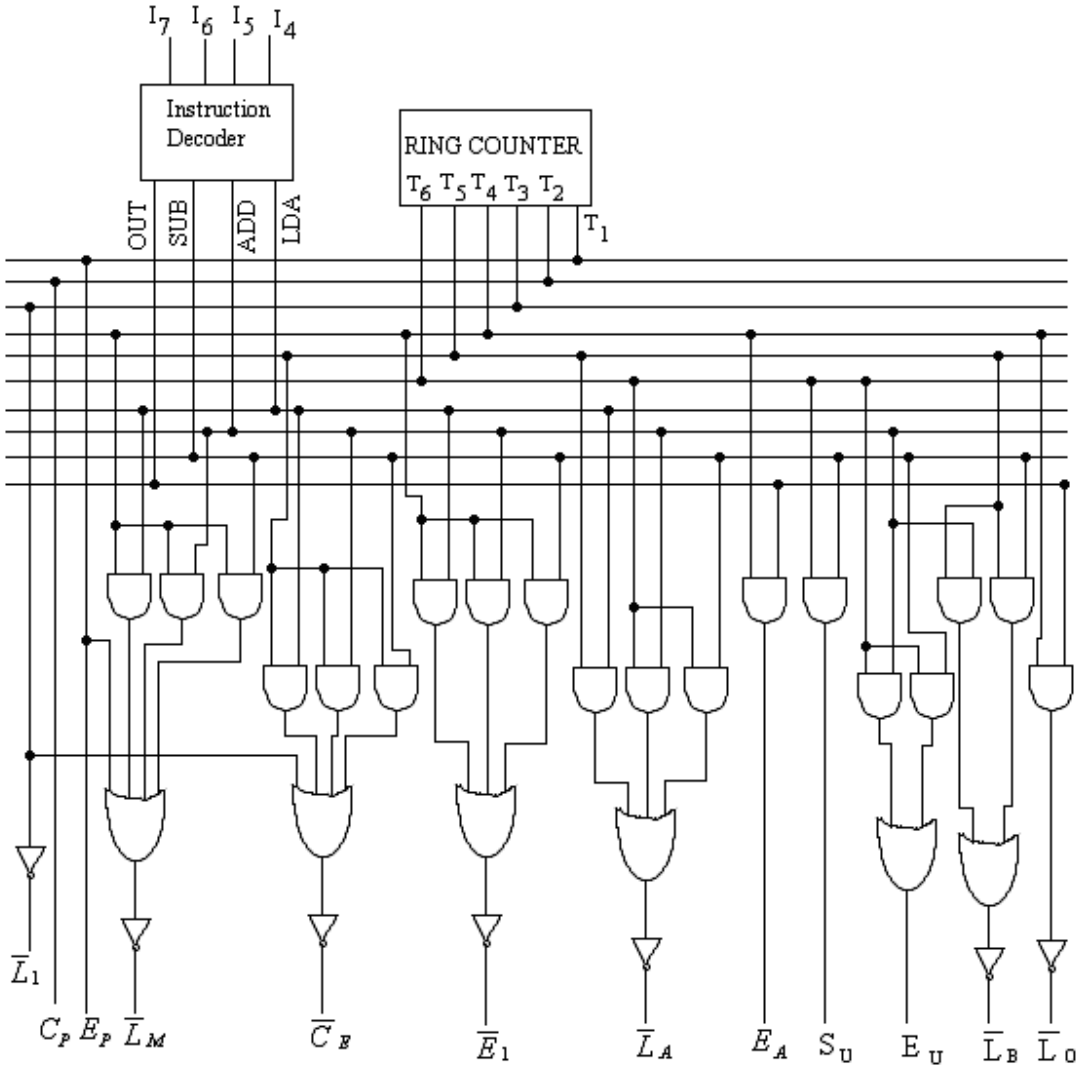

Fig. 2.19

2.5.5 Accumulator

Figure 2.20 shows the logic diagram of 8-bit buffer register known as accumulator which is designed using two ICs' IC1 and IC2 (both 74LS173). These ICs are configured as two-state output. The outputs of both the two ICs directly go to Adder-Subtractor. Three state switches send the content of accumulator to W-Bus when the signal E_A is high.

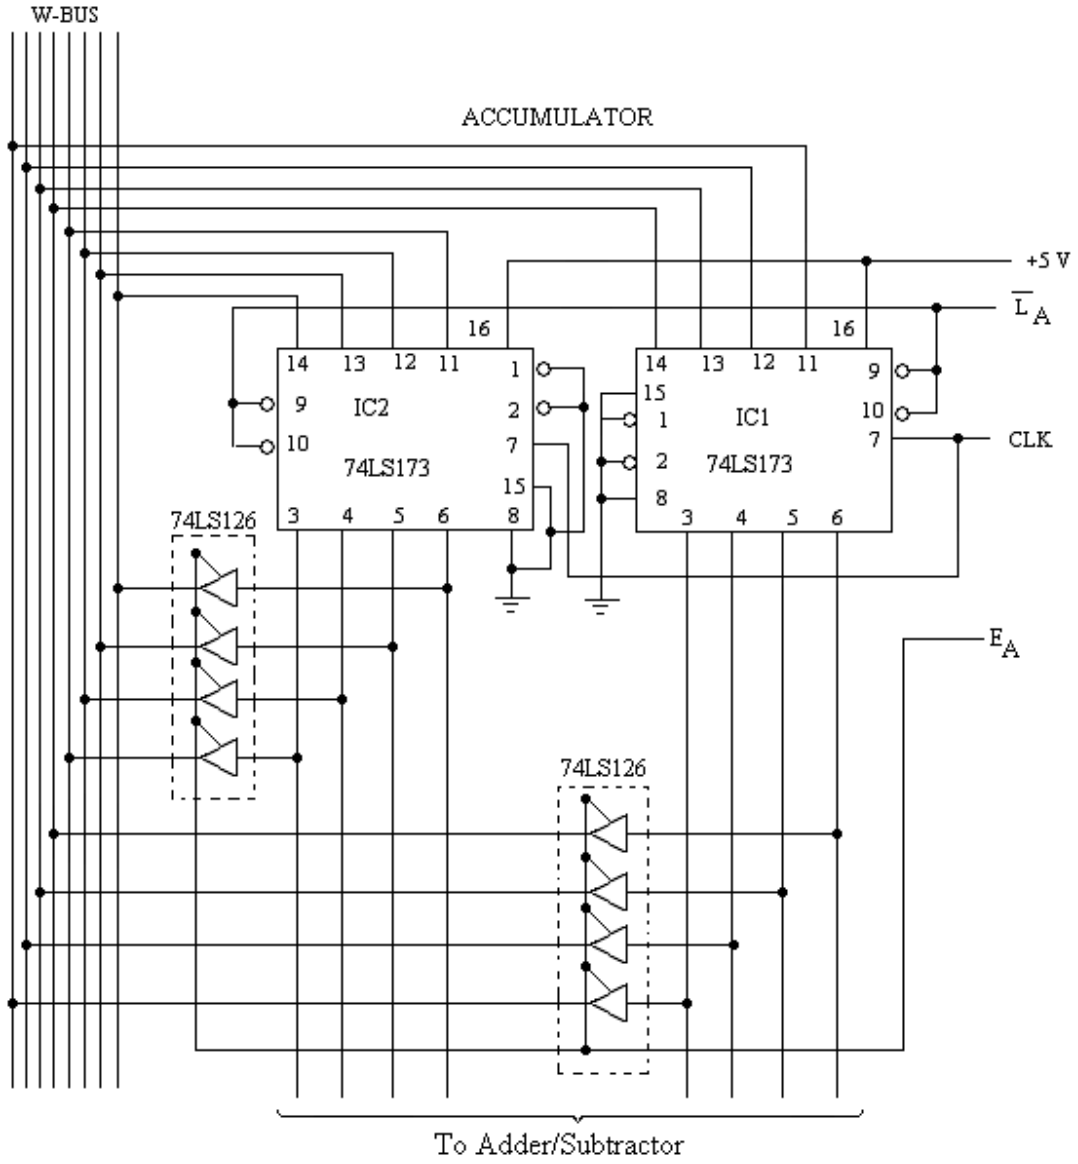

Fig. 2.20

2.5.6 Adder-Subtractor

Figure 2.21 shows the logic circuit used for Adder-subtractor of SAP-I computer. It basically consists of two 2's complement adder/subtractor ICs (7483). The data from the accumulator directly goes to the Adder-subtractor as shown in figure 2. . The outputs of B-register are also connected to these two ICs through eight exclusive-OR gates. The one terminal each of the eight exclusive-OR gates is being used as control Input (S_U). When S_U is low the content of B-register is directly loaded to Adder/Subtractor i.e. it will act as simple adder. If on the other hand S_U is high, 1's complement of B-register is being added to adder/subtractor ICs. Logic 1 is also added to LSB to form its as 2's complement (it therefore works as 2's complement subtractor). These two

adder/subtractor ICs give the 8-bit addition or subtraction. The 8-bit three state switches load the answer (sum or difference) to W-bus.

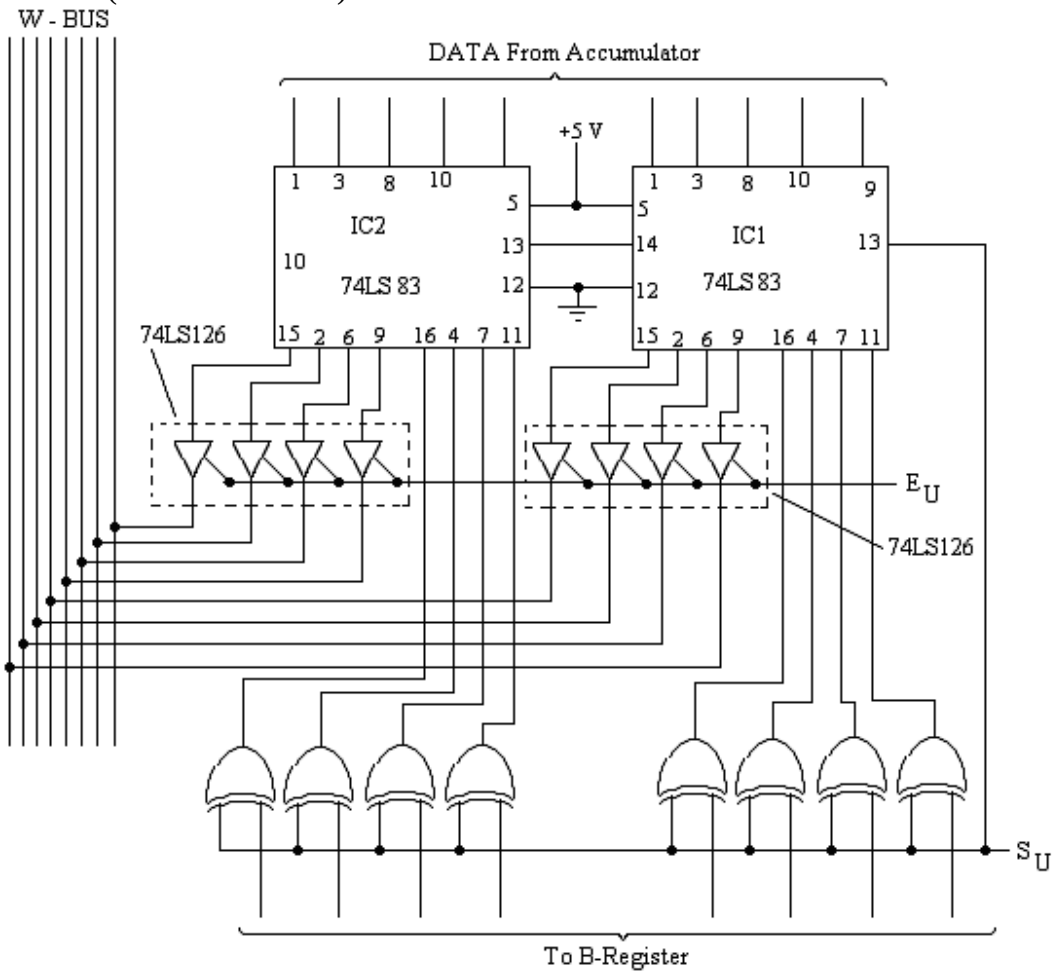

Fig. 2.21

2.5.7 B-Register

Similar to Accumulator, B-register is also designed using the Buffer register ICs 74LS173. The logic circuit diagram of this register is shown in figure 2.22. These two ICs are configured as two state register. When $\overline{L}_B$ is low, the data from the W-Bus is loaded to B-register and then transferred to Adder/Subtractor.

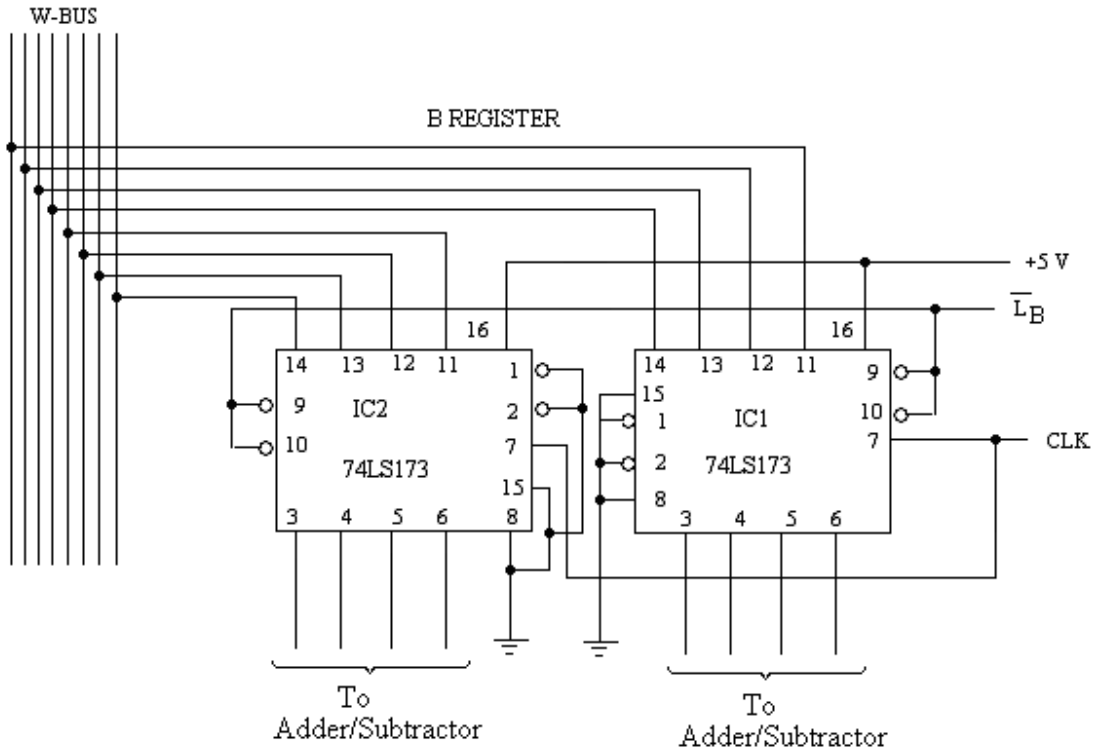

Fig. 2.22

2.5.8 Output Register

Output register is also formed by two state Buffer register using 74LS173 ICs. The output register with Binary display unit of SAP-I computer is shown in figure 2.23. When $\overline{L}_O$ is low, the data from the W-Bus will be loaded to output register. The output terminals of output register are connected to 8 LEDs, which will glow as per the data available at the output register.

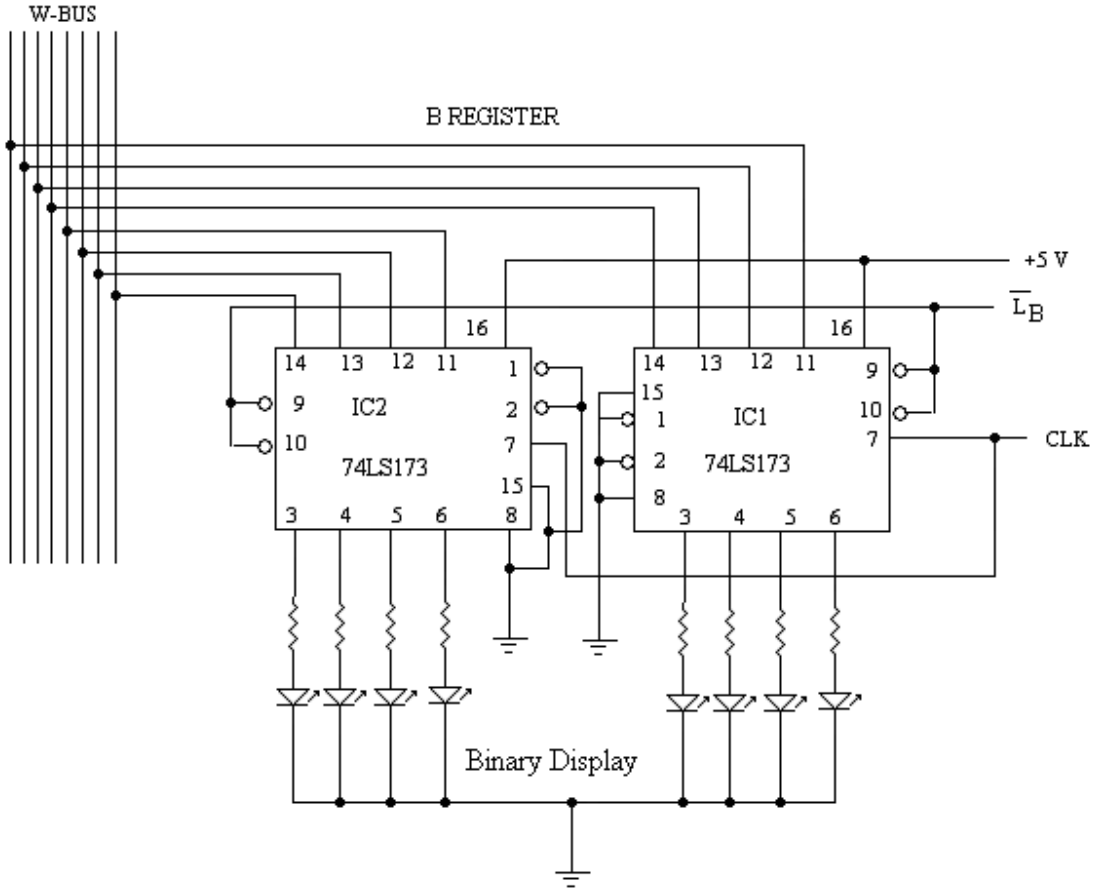

Fig.2.23

Problems

2.1 Draw the block diagram of SAP-I computer. Discuss the function of each block.

2.2 What is the function of Controller/Sequencer in SAP-I computer? How a control word is generate in SAP-I computer?

2.3 Draw the logic circuit diagram of Program counter and discuss its function.

2.4 Explain with the help of timing diagram the fetch and execution cycle of LDA-instruction.

2.5 Explain with the help of timing diagram the fetch and execution cycle of ADD-instruction.

2.6 Explain with the help of timing diagram the fetch and execution cycle of SUB-instruction.

2.7 Explain with the help of timing diagram the fetch and execution cycle of OUT-instruction.

2.8 Explain with the help of timing diagram the fetch and execution cycle of HLT-instruction. Further explain what will happen if HLT instruction is not given at the end of the program?

2.9 Differentiate between:

(i) Micro-instruction and Macro-instruction

(ii) Assembly language and machine language

(iii) Source program and object program

2.10 Explain the instruction set of SAP-I computer. What is the size of MAR of the SAP-computer?

2.11 Why the positive clock edge occurs half way through each T-state in SAP-I computer?

2.12 What is the role of instruction register in SAP-I computer? Draw the logic diagram for Instruction register of SAP-I computer?

2.13 Write an assembly language program that perform the following operation in SAP-I computer.

$$8-3+5+2-4$$

Use memory locations 7H to BH for the data. Write also its program in machine language.

2.14 Write an assembly language program for SAP-I computer that will display the result of $9+3-2$.

2.15 Write an assembly language program for SAP-I computer that will display the result of $7+3-2+4-1+6$.

Use AH to FH memory locations for starting the data.

2.16 Write an assembly language program for calculating the following expression $A+3B-2C$ on SAP-I computer. The data A, B and C are stored in memory locations 9 H to B H. Write also its machine language.

2.17 What are microinstructions for SUB and OUT instructions of SAP-I computer. Express the answer in binary also.

2.18 The timing diagram for Fetch and Execution cycle of ADD instruction is shown in figure 2.24. What are the microinstructions for Fetch and Execution cycle of ADD instruction?

3

SAP – II

In the preceding chapter of this book, the architecture, Instruction set and Programming of a conceptual computer named SAP-I computer was discussed. In order to understand the basic knowledge of a computer, it was the first step in the evolution towards the modern computers. The further step in this direction is SAP-II computer. The details of SAP-II computers will now be discussed.

3.1 ARCHITECTURE OF SAP-II COMPUTER

The architecture of another conceptual computer named as SAP-II computer is shown in figure 3.1. The SAP-II computer has more registers and other blocks, for giving more flexibility in programming. The architectural details of the Simple as Possible computer SAP-II are basically same as that of SAP-I, but SAP-II has more additional features which are given below:

(1) It is an eight bit computer, as 8-bit data can be processed in this computer. The SAP-I computer was also 8-bit computer.

(2) It has bidirectional BUS shown by double headed arrows, which indicate that the data can move either way after having the proper control signal. In SAP-I computer separate BUS is used for each way.

(3) The memory size of SAP-II computers is 64K (65536) words and each word is of 8-bit long. The data may be loaded or retrieved from the memory, through a buffer register known as Memory Data Register (MDR) or Memory Buffer Register (MBR).

The address for the location is 16 bits as $64K = 65536 = 2^{16}$.

The address will start from:

0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0

to

1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1

The hexadecimal equivalent of the address is

0 0 0 0 H to F F F F H.

However, memory size of SAP-I computers was only 16. As $2^4 = 16$, so 4 address lines were used.

(4) The width of the W-BUS is 16, since it has to carry a 16 bit address. The width of W-bus for SAP-I computer was only of 8-bits.

(5) The program counter of SAP-II computer is 16-bit wide as it has to send the address of 16 bits to W-BUS.

(6) Memory Address Register (MAR) of SAP-II computer is of 16 bits as it receives the address of 16-bits from the W-BUS.

(7) The controller sequencer of SAP-II computer generates a control word of bigger size than that of SAP-I computer; since it has to control more registers and blocks of the computer. The control word of SAP-I computers was of 12 bits.

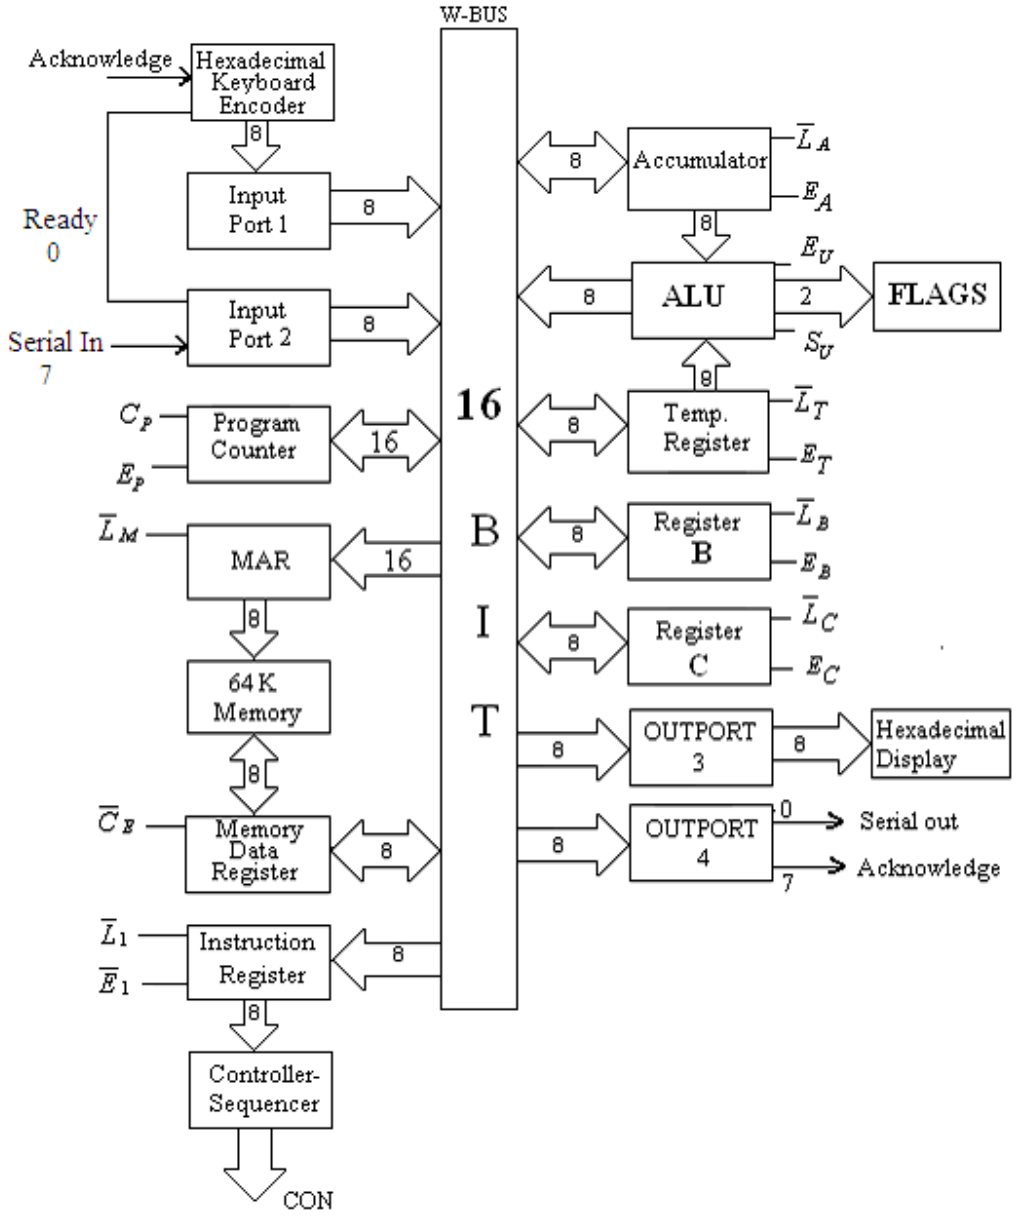

Fig. 3.1

(8) There are three registers in SAP-II computers namely Accumulator (Register A), Register B and Register C. All these registers are 8-bit registers. The registers B and C are general purpose registers. These registers give more flexibility in moving the data from one register to other register during the computer run. In SAP-I computer B-register was available for holding the data being added to or subtracted from the

accumulator. In SAP-II computers, there is a temporary register (T-register) for this purpose.

(9) SAP-II computer has Arithmetic and Logical unit (ALU) which can perform the arithmetic and logical operations on 8 bit data. Two flags (Sign flag **S** and Zero flag **Z**) are available with ALU. The accumulator content goes negative or zero during execution of some instructions. This affects the sign and zero flags. Figure 3.2 shows the circuit used for setting of flags of SAP-II computers.

It is clear from this figure that when accumulator content is zero all the bits (A_0 to A_7) are zero and the output of NOR gate is one. This NOR gate derives the AND gate (numbered 2), if the gating signal L_F is high and the flag will be updated. Similarly, if the accumulator content is negative, most significant bit (A_7) of the accumulator will be one which drives the lower AND gate (numbered 3) and sign flag will be updated when L_F is high. The sign flag will be set if accumulator content is negative and reset if positive. The zero flag will be set if accumulator content is zero and reset if it is non zero.

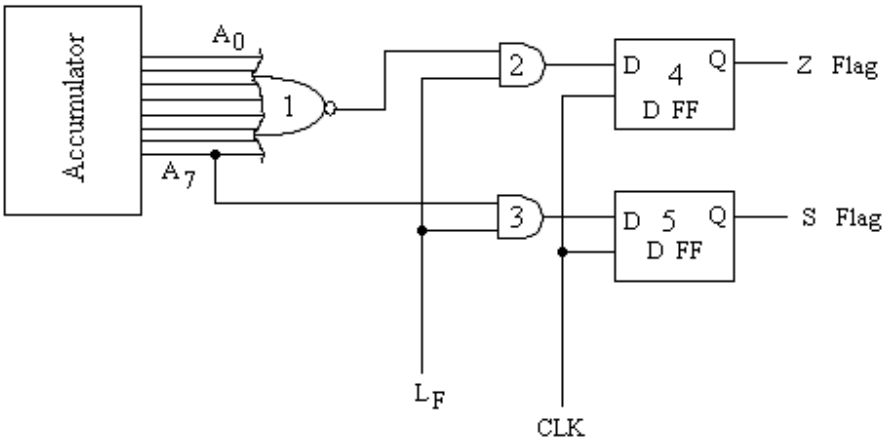

Fig. 3.2

(10) There are two input ports (Input Port-1 and Input Port-2) in SAP-II computers as shown in figure 3.1. A hexadecimal keyboard encoder is connected to Port 1. The instruction and data fed to the computer through this input port 1. The encoder sends a READY signal to bit 0 of Input Port-2. The data may also be accepted in serial form through the Input Port-2.

(11) SAP-II computer has two Output Ports namely output port-1 and output port-2. Through the output port-1, the processed data (answer from accumulator) can be visualized on the hexadecimal display. The accumulator content can also be sent to output port serially.

(12) Because of the availability of more registers and large size of memory, SAP-II computer has an instruction set with 42 instructions. SAP-I computer has only 5 instruction in its instruction set.

3.2 INSTRUCTION SET OF SAP-II COMPUTERS

As already discussed SAP-II computer has 42 instructions in its instruction set which are listed in table 3.1. These instructions are divided into 5 different categories as:

Memory Reference Instructions
Register Instructions
Jump and Call instructions
Logical Instructions
Miscellaneous Instructions

Table 3.1

Category	**Instruction**	**Op. Code**	**Operation**
Memory Reference instructions	LDA address	3A	$[\mathrm{A}] \leftarrow [\mathrm{M}_{\mathrm{address}}]$
	STA address	32	$[\mathrm{M}_{\mathrm{address}}] \leftarrow [\mathrm{A}]$
	MVI A, data	3E	$[\mathrm{A}] \leftarrow$ Data
	MVI B, data	06	$[\mathrm{B}] \leftarrow$ Data
	MVI C, data	0E	$[C] \leftarrow Data$
Register Instructions	MOV A, B	78	$[A] \leftarrow [B]$
	MOV A, C	79	$[A] \leftarrow [C]$
	MOV B, A	47	$[B] \leftarrow [A]$
	MOV B, C	41	$[B] \leftarrow [C]$
	MOV C, A	4F	$[C] \leftarrow [A]$
	MOV C, B	48	$[C] \leftarrow [B]$
	ADD B	80	$[A] \leftarrow [A] + [B]$
	ADD C	81	$[A] \leftarrow [A] + [C]$
	SUB B	90	$[A] \leftarrow [A] - [B]$
	SUB C	91	$[A] \leftarrow [A] - [C]$
	INR A	3C	$[A] \leftarrow [A] + 1$
	INR B	04	$[B] \leftarrow [B] + 1$
	INR C	0C	$[C] \leftarrow [C] + 1$
	DCR A	3D	$[A] \leftarrow [A] - 1$
	DCR B	05	$[B] \leftarrow [B] - 1$
	DCR C	0D	$[C] \leftarrow [C] - 1$
Jump and Call instructions	JMP address	C3	$[PC] \leftarrow Address$
	JM address	FA	$[PC] \leftarrow Address$ **;** if acc. content is negative.
	JZ address	CA	$[PC] \leftarrow Address$ **;** if acc. content is zero.
	JNZ address	C2	$[PC] \leftarrow Address$ **;** if acc. content is not zero.
	CALL address	CD	$Stack \leftarrow [PC]$ and

			$[PC] \leftarrow Address$
	RET	C9	$[PC] \leftarrow Stack$
Logical instructions	CMA	2F	$A \leftarrow \overline{A}$
	ANA B	A0	$A \leftarrow A.AND.B$
	ANA C	A1	$A \leftarrow A.AND.C$
	ORA B	B0	$A \leftarrow A.OR.B$
	ORA C	B1	$A \leftarrow A.OR.C$
	XRA B	A8	$A \leftarrow A \oplus B$
	XRA C	A9	$A \leftarrow A \oplus C$
	ANI, data	E6	$A \leftarrow A.AND.data$
	ORI, data	F6	$A \leftarrow A.OR.data$
	XRI, data	FE	$A \leftarrow A \oplus data$
Miscellaneous instruction	NOP	00	No operation
	IN Port	DB	$[A] \leftarrow [Portadress]$
	OUT Port	D3	$[Outport] \leftarrow [A]$
	RAL	17	Rotate acc. left
	RAR	1F	Rotate acc. right
	HLT	76	Stops Processing

The operation to be performed by each instruction has been explained in table 3.1. After going through these instructions, it will be possible to write complicated programs in solving the different problems.

The SAP-II computer has memory reference instruction like 'STA address" which allows to store the content of accumulator to the memory location whose address is given with the instruction. For example if accumulator has the content $A = 1\ 0\ 1\ 0\ 1\ 0\ 1\ 0$ before execution of an instruction. Let the instruction is

STA 2050 H

After execution of this instruction the memory location 2050 H will have the data

1 0 1 0 1 0 1 0.

i.e. $M_{2050H} = 10101010$

In register instructions, **MOV C, B** copies the content of B-register into C-register $(C \leftarrow B)$.

In Call instructions, the instruction 'CALL address' copies the present address of program counter to Stack and the given address with the instruction is copied into program counter. So whenever the next instruction is fetched, the program counter will send this new address. This instruction helps in jumping from the normal routine of the program to subroutine program. The instruction RET stands for return. This statement is used at the end of subroutine program and its sends back to the original program as the content of the stack is copied back to the program counter. In SAP-II computer there is, however, no register for Stack. The last two memory locations FFFE H and FFFF H are used for this purpose as shown in figure 3.3 i.e. these two locations are exclusively used for saving the return address of the subroutine program.

The SAP-II computer has the logical instructions such as 'ANA reg', 'ORA reg', 'XRA reg', 'ANI data', 'ORI data', 'XRI data' and 'CMA'. The 'ANA B' instruction

AND the contents of A register with the contents of B register bit by bit and the answer is loaded into accumulator.

In miscellaneous instructions, 'IN port' loads the data word from an input port to the accumulator.

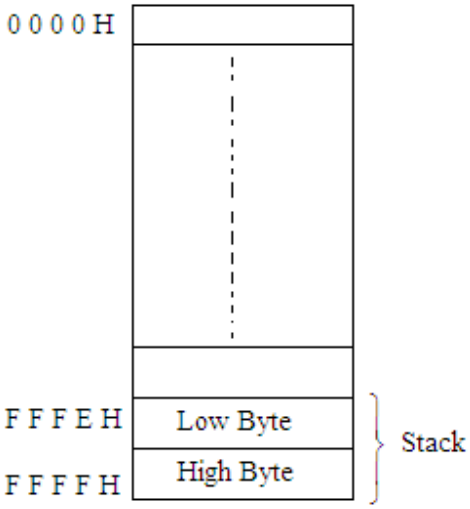

Fig. 3.3

The RAL instruction rotates the accumulator left. This instruction will shift all bits of accumulator content to the left and move the MSB into LSB position as illustrated in figure 3.4.

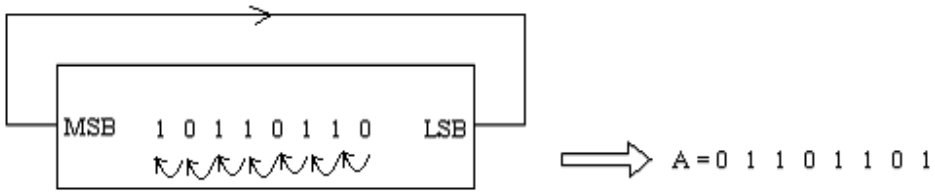

Fig.3.4

Similarly, the RAR instruction rotates the accumulator right. This instruction will shift all bits of accumulator content to the right and move the LSB into MSB position as illustrated in figure 3.5.

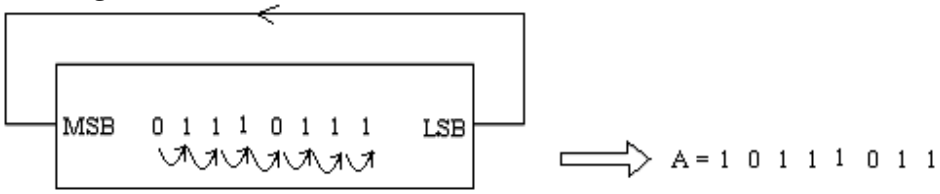

Fig. 3.5

3.3 MACHINE CYCLE AND INSTRUCTION CYCLE

It has been discussed in the last chapter that the SAP-I computer takes 6-T states to fetch and execute an instruction. These six states form a machine cycle. The number of T-states needed to fetch and execute an instruction is called Instruction cycle. So in SAP-I computer instruction cycle is machine cycle as shown in figure 3.6.

The SAP-II computer has, however, more than one machine cycle to fetch and execute an instruction. As shown in figure 3.7, first three T-states are used to fetch an

instruction and other 9 T-states are used for the execution of an instruction. So in SAP-II or other computers the instruction cycle may have two or more machine cycles. Table 3.2 shows the number of T-states used for the instruction cycle of each instruction.

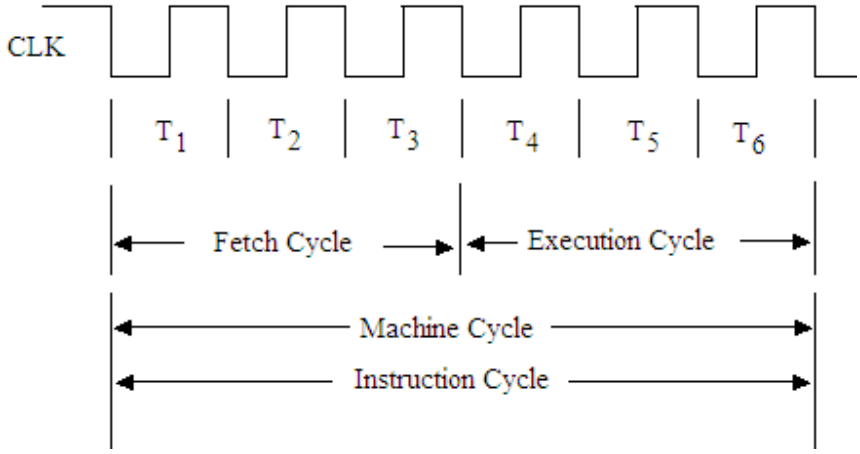

Fig. 3.6

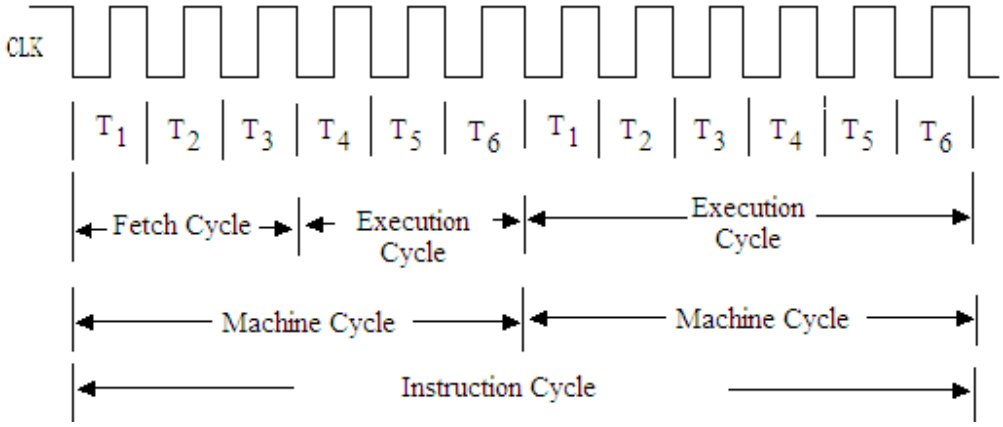

Fig. 3.7

The instruction 'STA address' takes 13 T-states to fetch and execute this instruction. If the system clock frequency is 3 MHz, then 'STA address' will take

$$13x\frac{1}{3}\mu\text{sec} = 4.33\mu\text{sec}$$

time to fetch and execute this instruction i.e. it is the time of instruction cycle of the instruction 'STA address'.

Table 3.2

Instruction	Addressing	No of T-states	Flags affected	No of bytes of instr.
LDA address	Direct	13	None	3
STA address	Direct	13	None	3

RAL	Implied	4	None	1
RAR	Implied	4	None	1
HLT	-	5	--	1

3.4 ADDRESSING MODES

There are various techniques to specify the data for instruction. These techniques are called addressing modes. SAP-II computer has the following addressing modes:

1. Direct Addressing
2. Register Addressing
3. Immediate Addressing
4. Implied Addressing

Direct Addressing

In this mode of addressing, the address of the operand is given in the instruction itself.

For example LDA 2100 H
OUT 03 H etc.

Register Addressing

In this mode of addressing, the operands are in registers.

For example MOV A , B
ADD C etc.

Immediate Addressing

In immediate addressing mode, the operand in specified in the instruction itself.

For example MVI B, 08 H
ANI 07 H etc.

Implied Addressing

There are certain instructions which operate on the contents of the accumulator. Such instructions do not require the address of the operand, since the operand is implied in the instruction itself. So this type of addressing mode is called as Implied Addressing.

For example CMA
RAL
RAR etc.

The addressing modes of all the instructions of SAP-II computers are given in table 3.2.

3.5 INSTRUCTION TYPES

The instruction set of SAP-II computer may be divided into three types. As already seen, there are different ways for specifying the data for instructions, so the machine codes of all instructions are not of same length. Following are the types of instructions:

(i) One Byte Instruction
(ii) Two Byte Instruction
(iii) Three Byte Instruction

One Byte Instruction

This type of instruction has only op code part of one byte and no operand is given. The instruction length is only of one byte. It can be stored only in one memory location.

For example MOV A, C
ADD C
CMA
RAL
RAR etc.

If 'MOV A, C' instruction is to be stored in some location say 2000 H, then its op code of one byte is to be fed in this memory location.

i.e. 2000 H 79 H

where 79 H is the op code of the instruction 'MOV A, C'.

Two Byte Instruction

In a two byte instruction, first byte of the instruction is its op code and second byte is the given data.

Such instruction is stored in two consecutive memory locations.

For example MVI A, 06 H
OUT 03 H
ANI 76 H etc.

In order to store the instruction say 'MVI A, 06 H' in the memory locations of the computer, we have to use two consecutive memory locations. In one memory location the op code of MVI A is to be stored and in the second location the data 06H is to be stored. This type of instruction to be stored in two locations say in 2101 H and 2102 H is given below:

2101H	3E H	(op code of MVI A)
2102H	06 H	(given data)

Three Byte Instruction

In a three byte instruction, first byte is used for its op code and second and third bytes are used for 16 bit address. Such an instruction is stored in three consecutive memory locations.

For example LDA 2100 H
STA 3000 H
JMP 2500 H etc.

In order to store the instruction say 'LDA 2100 H' three consecutive memory locations are to be used. In the first memory location op code of the instruction is stored, in second location lower byte of the address is to be stored and in the third byte upper byte of the address is to be stored. This instruction loaded in three consecutive memory location 2000H, 2001H and 2002H is given below:

2000H	3A H	(op code of LDA)
2001H	00 H	(Lower byte of address 2100 H)
2002H	21 H	(Upper byte of address 2100 H)

The type of instructions of all the 42 instructions of SAP-II computer is also given in table 3.2.

3.6 FLAGS

As already discussed, there are two flags associated with the accumulator of SAP-II computer, sign flag (S) and Zero flag (Z). These flags may be set or reset during certain instructions. If the accumulator content is negative after execution of certain instruction the sign flag is set otherwise it is reset. Similarly, if the accumulator content is zero after the operation of certain instruction the zero flag is set otherwise reset. These instructions which affect the flags are listed in table 3.3.

Table 3.3

Instruction	Flags affected
ADD	S, Z
SUB	S, Z
INR	S, Z
DCR	S, Z
ANA	S, Z
ORA	S, Z
ANI	S, Z
ORI	S, Z
XRI	S, Z

For example in ADD instruction say ADD B, the contents of B register gets added with the accumulator content and after addition the result is stored in accumulator. If the result is zero then zero flag is set otherwise reset. Similarly, if the result is negative the sign flag is set otherwise reset.

In INR or DCR instructions both sign and zero flags are affected. For example if there is an instruction INR B, the content of B register is incremented by sending the contents to accumulator and adds 1 to it. The result is then sent back to B register. If the accumulator goes negative while INR instruction is executed, the sign flag is set; and if the accumulator content is zero then the zero flag is set.

3.7 ASSEMBLY LANGUAGE PROGRAMMING

The programming of the problem is generally written in assembly language. The assembly language is written in mnemonics. The mnemonics are the initials or short form of the English word of the operation to be performed by the instruction. Assembly language statements are written in standard format as given below:

Label Mnemonic Operand Comment

Label A label is a symbol or group of symbols used to represent an address of the location which is not specifically known at the time of program is written. The label can be one to six characters, the first character of which must be a letter. Following are the acceptable labels.
NEXT, BACK, DELAY, A2 etc.

Mnemonic Short form of the operation to be performed.

Operand Operand is the data on which the operation is performed. It can be a data, memory address, register or port address.

Comment The comment statement is started with the semicolon. It gives the idea of the program to the user. The comments are not the part of the machine language program.

The program written in assembly language can be converted to machine language by hand. For writing the program in machine language, the starting address, where the program is to be stored should be known. Now the op code of the instruction is to be written in first location (starting address) and in the consecutive memory locations data /address of the operand is written. While storing the address in the memory locations, lower byte of he address is stored first then the upper byte as discussed above.

Example 3.1 *Write assembly language program using the instructions of SAP-II computer of the following statement. Also write the program in machine language.*

Load the contents of memory locations 2100 H and 2101 H in B-register and C-register respectively. The content of memory locations 2100 H and 2101H are 16 H and 19 H respectively.

Solution.

Label Mnemonic Operand Comment

	LDA	2100H	; Loads the content of 2100H into accumulator.
	MOV B,	A	; moves the content of accumulator to B-register ($B \leftarrow A$).
	LDA	2101H	; Loads the content of 2100H into accumulator.
	MOV C,	A	; moves the content of accumulator to C-register ($C \leftarrow A$).
	HLT		; Stop processing.

The assembly language program may be converted to machine language by writing the op codes of the instructions as given below. Let the starting address of the program is 2000H.

Memory Address	**Content**	
2000 H	3A H	LDA 2100 H
2001 H	00 H	
2002 H	21 H	
2003 H	47 H	MOV B, A
2004 H	3A H	LDA 2101 H
2005 H	01 H	
2006 H	21 H	
2007 H	4F H	MOV C, A
2008 H	76 H	HLT
2101 H	16 H	Data
2102 H	19 H	Data

Example 3.2 *Write an assembly language program to find the 2's complement of a hexadecimal number. The hexadecimal number 6A H is stored in memory location 2100H and the answer is to be stored in 2101 H. Use SAP-II instructions to program it.*

Solution.

Label	**Mnemonic**	**Operand**	**Comment**
	LDA	2100 H	; Loads the content of 2100 H into accumulator.
	CMA		; Complements the accumulator content (1's complement).
	INR A		; 1 is added to the accumulator content to get the 2's complement.
	STA	2101 H	; Loads the accumulator contents into memory location 2101 H.
	HLT		; Stop processing.

Example 3.3 *Write an assembly language program using SAP-II instructions to add two numbers (decimal) 38 and 64, then subtract decimal number 3 from the sum. The final answer is to be stored in memory location 2100 H.*

Solution. First of all decimal numbers 38 and 64 should be converted to hexadecimal numbers, as it works in hexadecimal.

Decimal number 38 = 26 H

Decimal number 64 = 40 H

Label	Mnemonic	Operand	Comment
	MVI A,	26 H	; Loads the first number to accumulator.
	MVI B,	40 H	; Loads the second number to B-register.
	MVI C,	03 H	; Loads the third number to C-register.
	ADD B		; Adds the contents of B-register with the contents of accumulator and the answer is stored in A.
	SUB C		; Content of C gets subtracted from accumulator and difference is stored in A.
	STA	2100 H	; Answer is stored in 2100 H location.
	HLT		; Stop processing.

Example 3.4 *Write a program in assembly language for SAP-II computer to mask off the least significant 4 bits of a given hexadecimal number. The answer should be stored in memory location 2200 H. Let the given number is B3 H.*

Solution. The binary equivalent of B3 H is 1011 0011. The masking of the 4 least significant bits 0011 means to make 0011 to 0000. However, the four most significant bits should not be changed.

This can be done if the given number is ANDed with F0 H (1111 0000). In doing so when 4 most significant bits are ANDed with 1111 no change will be there, but 4 least significant bits will be 0000 as required. The assembly language program for this will be as follows:

Label	Mnemonic	Operand	Comment
	MVI A,	B3 H	; Loads the number B3H to accumulator.
	ANI	F0 H	; ANDs the accumulator with F0H and answer is loaded to accumulator.
	STA	2200 H	; Answer is stored in 2200 H location.
	HLT		; Stop processing.

Example 3.5 *Write a program in assembly language for SAP-II computer to load a number 79 H in B-register and mask off all bits except* A_2 *bit. The result is to be transferred to C-register.*

Solution. To mask off the third LSB (A_2 bit) the ANDing of the given content will be with FBH (11111011). The program will be as given below:

Label	Mnemonic	Operand	Comment
	MVI B,	79 H	; Loads the number 79 H to accumulator.
	MOV A,	B	; Moves the content of B-register to accumulator.

	ANI	FB H	; ANDs the accumulator with FB H and answer is loaded to accumulator.
	MOV C,	A	; Answer is loaded to C-register.
.	HLT		; Stop processing.

Example 3.6 *Write a program in assembly language for SAP-II computer to interchange (swap) the contents of two memory locations 2100 H and 2101 H.*

Solution. The program is given below which is self explanatory.

Label	Mnemonic	Operand	Comment
	LDA	2100H	; Loads the content of 2100H into accumulator.
	MOV B,	A	; Moves the content of Acc to B-register.
	LDA	2101 H	; Loads the content of 2101H into accumulator.
	STA	2100 H	; Loads the acc. content to 2100 H location.
	MOV A,	B	; Moves the content of B-register to Acc.
	STA	2101 H	; Loads the acc. content to 2101 H location.
	HLT		; Stop processing.

Example 3.7 *Write a program in assembly language for SAP-II computer to multiply two decimal numbers 23 and 9 and store the answer in some memory location. Also write this program in machine language.*

Solution. Hexadecimal equivalent of decimal number 23 is 17 H.

The multiplication of these two numbers may be obtained by adding 23 (17 H) by 9 times in the accumulator which should be 00 H at the beginning. So the program of this problem may be as given below:

Label	Mnemonic	Operand	Comment
	MVI A,	00 H	; Loads the acc. 00 H. $[A] \leftarrow 00H$.
	MVI B,	17 H	; Loads B-register with 17H $[B] \leftarrow 17H$.
	MVI C,	09 H	; Loads C-register with 09H $[C] \leftarrow 09H$.
AGAIN	ADD B		; Adds the content of B-register to acc.
	DCR C		; Decrements C-register.
	JZ	END	; Checks for zero; if zero jump to END.
	JMP	AGAIN	; Repeats the addition.
END	STA	2100	; Stores the answer to memory location 2100 H.
	HLT		; Stop processing.

The program can be written in machine language stating at address 2000 H as given below:

Memory Address	Content	
2000 H	3E H	MVI A, 00 H
2001 H	00 H	
2002 H	06 H	MVI B, 17 H
2003 H	17 H	
2004 H	0E H	MVI C, 09 H
2005 H	09 H	
2006 H	80 H	ADD B
2007 H	0D H	DCR C
2008 H	CA H	JZ 200E H
2009 H	0E H	
200A H	20 H	
200B H	C3 H	JMP 2006 H
200C H	06 H	
200D H	20 H	
200E H	32 H	STA 2100 H
200F H	00 H	
2010 H	21 H	
2011 H	76 H	

Alternative method of writing this program using JNZ is as given below:

Label	Mnemonic	Operand	Comment
	MVI A,	00 H	; Loads the acc. 00 H. $[A] \leftarrow 00H$.
	MVI B,	17 H	; Loads B-register with 17 H $[B] \leftarrow 17H$.
	MVI C,	09 H	; Loads C-register with 09 H $[C] \leftarrow 09H$.
AGAIN	ADD B		; Adds the content of B-register to acc.
	DCR C		; Decrements C-register.
	JNZ	AGAIN	; Repeats the addition if the content of C-register is not zero.
	STA	2100 H	; Stores the answer to memory location 2100 H.
	HLT		; Stop processing.

This program can also be written by using subroutine program as follows:

Main Program

Label	Mnemonic	Operand	Comment
	MVI A,	00 H	; Loads the acc. 00 H. $[A] \leftarrow 00H$.
	MVI B,	17 H	; Loads B-register with 17 H $[B] \leftarrow 17H$.
	MVI C,	09 H	; Loads C-register with 09H $[C] \leftarrow 09H$.
	CALL	MUL	; Calls subroutine program for multiplication.

	STA	2100 H	; Stores the answer to memory location 2100 H.
	HLT		; Stop processing.

Subroutine Program

Label	Mnemonic	Operand	Comment
MUL	ADD B		; Adds the content of B-register to acc.
	DCR C		;Decrements C-register.
	JNZ	MUL	; Repeats the addition if the content of C-register is not zero.
	RET		; Returns to main program.

3.8 DELAY CALCULATIONS

Through programming time delay can be introduced, which is very useful in various applications such as digital clocks, traffic controls, digital process control and other data transfer controls. Time delay can be introduced by loading the registers with some desired number and then decremented through the loops to zero value. The delay introduced in the system will depend on the clock period of the system and the number of times the instructions are executed inside the loop.

To generate very small delay only one register can be used. Consider a subroutine program given below in which C-register is loaded with 10 H (decimal number 16). It is decremented in a loop to make it zero. Figure 3.8 shows the flow chart for the same.

Label	Mnemonic	Operand	No. of T-states
	MVI C,	10 H	7
LOOP	DCR C		4
	JNZ	LOOP	10/7
	RET		10

In this program the instruction MVI C, 10 H is executed only once and it takes 7 T-states to execute.

The instruction DCR C is executed 16 times and thus takes $16 \times 4 = 64$ T-states, since DCR instruction takes 4 T-states for its execution.

For the execution of JNZ instruction, it will go to loop 15 times, as the content of C-register will not be zero. So $15 \times 10 = 150$ T-states will be used in its calculation (till the content of C-register is not zero). When the contents of C-register becomes zero, it will jump to loop and it will take 7 T-states. For the execution of RET statement it will take 10 T-states.

Thus total number of T-states taken for the execution of this program will be given by:

Mnemonic	T-states
MVI C, 10 H	$7 \times 1 = 7$
DCR C	$4 \times 16 = 64$
JNZ	$10 \times 15 + 1 \times 7 = 157$
RET	$1 \times 10 = 10$
Total	**238 T-states**

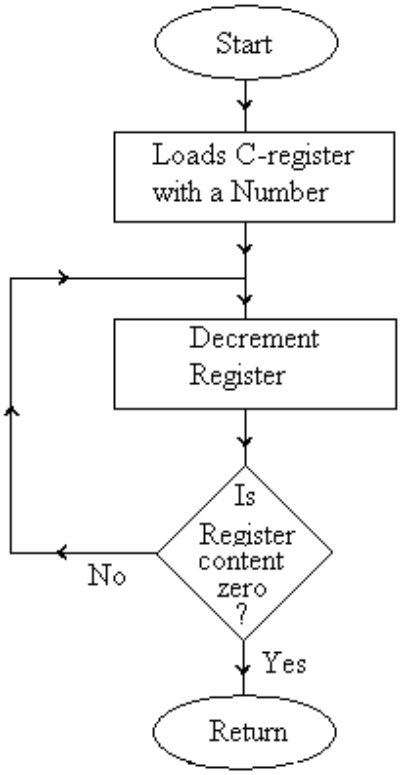

Fig. 3.8

Total 238 T-states are used for the execution of this program. If the system frequency is 2 MHz, the time taken by one T-state is $\frac{1}{2x10^6}\text{sec} = 0.5\mu\text{sec}$.

The total time delay introduced in the execution of this program is:

$$\text{Time delay} = 238x0.5\mu\text{sec}$$
$$= 119\mu\text{sec}$$
$$= 0.119\,\text{msec}$$

Maximum delay with this register C may be obtained by loading the number FF H (decimal number 255) in C-register. The maximum delay thus is:

MVI C, FF H	$7\,\text{x}\,1 = 7$
DCR C	$4\,\text{x}\,255 = 1020$
JNZ	$10\,\text{x}\,254 + 1\,\text{x}\,7 = 2547$
RET	$1\,\text{x}\,10 = 10$
Total	**3584 T-states**

$$\text{Time delay} = 3584x0.5\mu\text{sec}$$
$$= 1.792\,\text{msec}$$

Total delay introduced by the computer using only one register may be given in the following general form as:

$$T_{Delay} = [1x7 + 4N + (N-1)x10 + 1x7 + 10]x \text{ time of one T-state.}$$

where N is the decimal number given with the register.

$$= [14N + 14]x \text{ time of one T-state.}$$
$$= 14[N + 1]x \text{ time of one T-state.}$$

As discussed earlier the total time delay introduced by a register is 1.79 millisec if system clock frequency is 2 MHz. To introduce more time delay two registers may be used as shown in the flow chart shown in figure 3. 9, in which register B is used for the outer loop and register C is used for the inner loop.

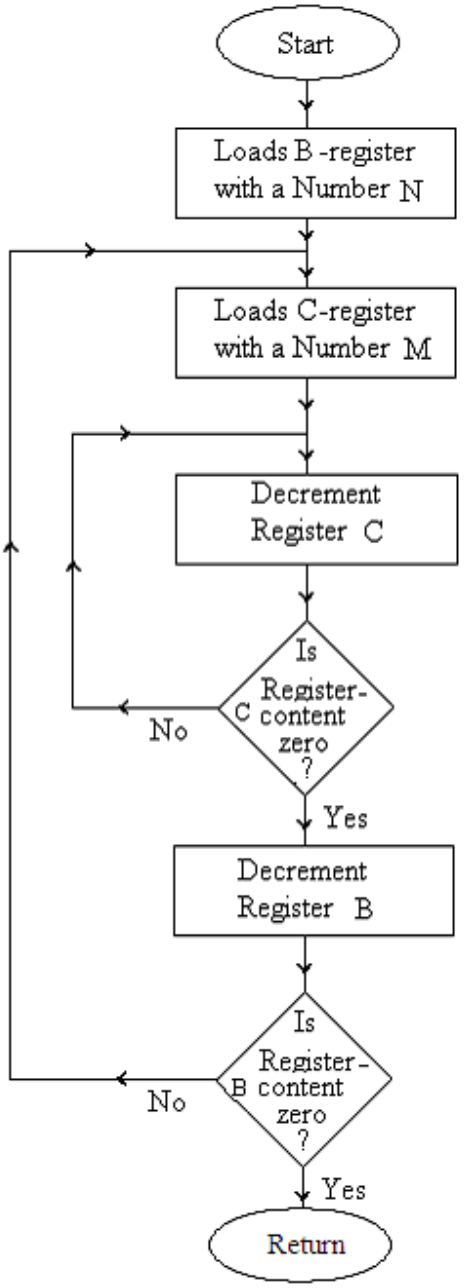

Fig. 3.9

Label	**Mnemonic**	**Operand**	**No. of T-states**
	MVI B,	M H	7
LOOP1	MVI C,	N H	7
LOOP	DCR C		4

JNZ	LOOP	10/7
DCR B		4
JNZ	LOOP1	10/7
RET		10

Total T-states used in this program will be given by:

$$= 1x7 + M\underbrace{[1x7}_{\text{MVI}} + \underbrace{Nx4}_{\text{DCR}} + \underbrace{(N-1)X10}_{\text{JNZ}} + \underbrace{1x7]}_{\text{JNZ}} + \underbrace{(Mx4)}_{\text{DCR}} + \underbrace{(M-1)x10}_{\text{JNZ}} + \underbrace{1x7}_{\text{JNZ}} + \underbrace{1x10}_{\text{RET}}$$

$$= 1x7 + M[7 + 4N + 10N - 10 + 7] + 4M + 10M - 10 + 7 + 10$$

$$= 14 + M[14N + 4] + 14M$$

$$= 14MN + 18M + 14$$

This is the general form for calculating the number of T-states of the program given above, in which M is the counts in register-B (in decimal number) in outer loop and N is the counts in register-C (in decimal number) in inner loop.

Total time delay is therefore given by:

$$T_{Delay} = (14MN + 18M + 14)\text{x Time of one T-state}$$

Example 3.8 *Write a delay subroutine program for SAP-II computer to introduce a time delay of 1 millisec using only one register. Let the system frequency is 2 MHz.*

Solution. System frequency = 2 MHz

Time delay of T-state = 0.5 μsec.

We shall now find the value of N to be stored to the register.

$$T_{Delay} = 14[N + 1]x\,0.5\ \mu\text{sec}$$

$$1000\ \mu\text{sec} = 14[N + 1]x0.5\,\mu\text{sec}$$

$$N = \frac{1000}{7} - 1$$

$$= \frac{993}{7} \cong 142 \text{ decimal number}$$

$$142 = 8\text{E H}$$

So the program for the delay of 1 millisec is as given below:

Label	**Mnemonic**	**Operand**
	MVI C,	8E H
LOOP	DCR C	
	JNZ	LOOP
	RET	

Example 3.9 *Write a delay subroutine program for SAP-II computer to introduce a time delay of 10 millisec using two registers. Decimal number 10 may be stored in register B (for outer loop). Let the system frequency is 2 MHz.*

Solution. System frequency = 2 MHz

In this case M = 10_{10} = 0A H

N is to be calculated as:

$$T_{Delay} = (14MN + 18M + 14)\text{x Time of one T-state}$$

Time of T-state = 0.5 μsec

$$10ms = (14x10xN + 18x10 + 14)x0.5\mu S$$

$$10000\mu s = (140N + 194)x0.5\mu S$$
$$20000 = (140N + 194)$$
$$140N = (20000 - 194)$$
$$N = \frac{19806}{140} = 142 = 8E \text{ H}$$

The Subroutine program for the required time delay is therefore given as:

Label	**Mnemonic**	**Operand**
	MVI B,	0A H
LOOP1	MVI C,	8E H
LOOP	DCR C	
	JNZ	LOOP
	DCR B	
	JNZ	LOOP1
	RET	

Example 3.10 *(a) What will be the time delay introduced in the computer, if the following subroutine program is executed. Assume the system frequency is 2 MHz.*

	MVI B,	*64 H*
LOOP1	*MVI C,*	*8E H*
LOOP	*DCR C*	
	JNZ	*LOOP*
	DCR B	
	JNZ	*LOOP1*
	RET	

(b) How much maximum delay can be introduced by this subroutine program?
(c) Modify this program to introduce a time delay of 1 sec.
(d) Modify this program to introduce a time delay of 10 sec.

Solution. In this subroutine program M = 64 H = 100_{10}
N = 8E H = 142_{10}
Time of one T-state = 0.5 μsec

$$T_{Delay} = (14MN + 18M + 14) \text{ x Time of one T-state}$$
$$= (14MN + 18M + 14) \text{ x } 0.5\mu\text{sec}$$
$$= (14x100x142 + 18x100 + 14) \text{ x } 0.5\mu\text{sec}$$
$$= (198800 + 1800 + 14) \text{ x } 0.5\mu\text{sec}$$
$$= 200614 \text{ x } 0.5\mu\text{sec}$$
$$= 100307 \ \mu\text{sec}$$
$$= 100.3 \text{ msec}$$
$$\cong 0.1 \text{ sec}$$

Approx. 0.1 sec delay is introduced by this subroutine program.

(b) The maximum time delay that can be introduced by this subroutine program is calculated if we consider the maximum value of M and N as FF H.

i.e. M = FF H = 255_{10}
N = FF H = 255_{10}

$$T_{Delay} = (14MN + 18M + 14) \text{ x Time of one T-state}$$
$$= (14MN + 18M + 14) \text{ x } 0.5\mu\text{sec}$$

$$= (14x255x255 + 18x255 + 14) \text{ x } 0.5\mu\text{sec}$$
$$= 914954 \text{ x } 0.5\mu\text{sec}$$
$$= 457477 \ \mu\text{sec}$$
$$\cong 0.46 \text{ sec}$$

(c) To introduce a time delay of 1 sec, the given program can be run 10 times using one more register say A-register. The modified program is given below:

Label	**Mnemonic**	**Operand**
	MVI A,	0A H
LOPP3	MVI B,	64 H
LOOP2	MVI C,	8E H
LOOP1	DCR C	
	JNZ	LOOP1
	DCR B	
	JNZ	LOOP2
	DCR A	
	JNZ	LOOP3
	RET	

(d) To introduce a time delay of 10 sec, in the above program 64 H (100_{10}) can be taken in place of 0A H (10_{10}). The subroutine program will be as given below:

Label	**Mnemonic**	**Operand**
	MVI A,	64 H
LOPP3	MVI B,	64 H
LOOP2	MVI C,	8E H
LOOP1	DCR C	
	JNZ	LOOP1
	DCR B	
	JNZ	LOOP2
	DCR A	
	JNZ	LOOP3
	RET	

Example 3.11 *Write a program in assembly language of SAP-II computer to count continuously in hexadecimal from FF H to 00 H. Use subroutine program also to set up a one millisecond delay between each count and display the number at one of the output port. Assume the system frequency is 2 MHz.*

Solution. For its programming load a count 00 H in one register say B-register. Decrement the content of B-register, so that in B-register the counts are FF H. Display this count on one of the output port say 04 H. Then introduce a delay of 1 millisec in a subroutine program. After the delay, decrement the counts in B-register and proceed continuously as discussed above.

The program is given below:

Main Program

Label	**Mnemonic**	**Operand**	**Comment**
	MVI B,	00 H	; Loads the count 00 H in B-register. $[B] \leftarrow 00H$.

```
START   DCR B           ;  Decrements the counts of B-register.
        CALL   DELAY    ;  Calls the delay subroutine program.
        MOV A,  B       ;  Moves the content of B to A.
        OUT    PORT 04 H;  Displays the data at the output port.
        JMP    START
```

Subroutine Program (Delay program of 1msec)

```
Label   Mnemonic   Operand
DELAY   MVI C      8E H
LOOP    DCR C
        JNZ        LOOP
        RET
```

Subroutine program is the same as discussed in example 3.7.

Example 3.12 *Suppose SAP-II computer can input a data (one byte) from port 2. Write an assembly language program to find if the bit 1 (A_1) is zero or one. If the bit 1 is one, it should load the accumulator with ASCII Y otherwise ASCII N. The accumulator data should be available at output port 4. The hexadecimal number for ASCII Y is 59 H and for ASCII N is 4E H.*

Solution.

```
Label   Mnemonic   Operand   Comment
        IN         02 H      ;  Input a byte (data) from input port 02H.
        ANI        02 H      ;  Isolate bit A1.
        JZ         NO        ;  Jump if A1 is zero.
        MVI A,     59 H      ;  Loads Y to Acc.
        JMP        END       ;  Jump to END.
NO      MVI A,     4E H      ;  Loads N to Acc.
END     OUT        04 H      ;  Output is available at port 04 H.
        HLT                  ;  Stop processing.
```

Example 3.13 *Write a program in assembly language of SAP-II computer to subtract a number stored in memory location 2100 H from the number in memory location 2101 H using addition method. The result should be stored in memory location 2102 H. If the result is negative, memory location should be loaded with 00 H.*

Solution. In this problem subtraction is to be carried out using addition method. So we have to add 2's complement of the number in memory location 2101 H.

```
Label   Mnemonic   Operand   Comment
        LDA        2100 H    ;  Loads the Acc. the content stored in 2100 H.
        CMA                  ;  Takes 1's complement of the number in Acc.
        INR A                :  Acc. content is added with to get 2's complement in Acc.
```

```
        MOV B,    A          ; Moves the Acc. content to B-register.
        LDA       2101 H     ; Loads the Acc. the content stored in 2101 H (second number).
        ADD B                ; Adds 2's complement of the number with Acc.
        JM        END        ; Jump if the sum is negative.
        STA       2102 H     ; Stores the answer if positive.
        HLT                  ; Stop processing.
END     MVI A,    00 H       ; Moves 00 H to Acc.
        STA       2102 H     ; If answer is negative store 00 H to 2102 H.
        HLT                  ; Stop processing.
```

Example 3.14 *Write a program in assembly language using SAP-II instructions that inputs a byte from port 2 and determine if decimal number is even or odd. If the input byte is even load FF H otherwise 00 H to memory location 2500 H.*

Solution.

Label	Mnemonic	Operand	Comment
	IN	02 H	; Input a byte (data) from input port 02H.
	ANI	01 H	; Isolate bit A_0.
	JNZ	ODD	; Jump if Odd.
	MVI A,	FF H	; Loads FF H to Acc.
	JMP	END	; jump to END.
ODD	MVI A,	00 H	; Loads 00 H to Acc.
END	STA	2500 H	; Stores the answer in 2500 H.
	HLT		; Stop processing.

PROBLEMS

1. Draw the block diagram of the architecture of SAP-II computers. Discuss the working of each block.
2. What is the difference between the architectures of SAP-I and SAP-II computers?
3. How the sign and zero flags work in arithmetic and logic unit of SAP-II computers?
4. Name and discuss the five different categories in which the instruction set of SAP-II computers are divided.
5. Name and discuss the different addressing modes to specify the instruction of SAP-II computers.
6. Discuss Implied addressing to specify the data of instructions of SAP-II computers.
7. Describe with examples one byte, two byte and three byte instructions of SAP-II computers.
8. What is the difference between assembly language program and machine language program? What do you understand by mnemonics?

9. How delay is introduced through software in SAP-II computers using only one register? How much maximum delay can be introduced with one register if the frequency of the clock is (i) 1 MHz (ii) 3 MHz?
10. How much delay can be introduced using two registers in SAP-II computers, if the system frequency is 2 MHz?
11. Write the subroutine program to introduce a delay of 1 sec using all the three registers of SAP-II computers. Further assume that the system clock frequency is 2 MHz.
12. Write a program in assembly language using SAP-II instructions to multiply the two decimal numbers 13 and 10. The answer should be stored in memory location 2100 H.
13. Write a program in assembly language using SAP-II instructions to complement a number lying at 2100 H memory location. Store the complement at 2101 H.
14 Write a program in assembly language using SAP-II instructions to perform the following arithmetic operation:

$$X + Y - Z - W$$

where X, Y, Z and W are hexadecimal numbers stored in memory locations 2101 H to 2104 H. The final answer should be stored in 2100 H. Assume that there is no carry or borrow.

15. Write a program in assembly language using SAP-II instructions to get 2's complement of a number stored in memory location 2501 H. Store the answer at 2502 H .
16. Write a program in assembly language using SAP-II instructions to add decimal numbers 70 and 36. Answer is to be stored in memory location 2100 H.
17. Write a program in assembly language using SAP-II instructions to multiply two decimal numbers 33 and 6 and store the answer in memory location 2100 H. Use subroutine for multiplication.
18. Write a subroutine program (in assembly language of SAP-II) to introduce a time delay of 20 msec. Let the system frequency is 2 MHz.
19. Write a subroutine program (in assembly language of SAP-II) to introduce a time delay of 1 minute. Let the system frequency is 1 MHz.
20. Write an assembly language program using SAP-II instructions to mask off A_1 and A_2 bits of a given number. Let the given number is 6E H.

4

SAP – III

In this chapter, programming model and instruction set of SAP-III computer will be discussed. After the study of this computer we will be in a position to understand the details of the popular 8-bit microprocessor 8085 with ease.

4.1 PROGRAMMING MODEL OF SAP-III COMPUTER

One step head of the evolution of modern computers is the 8-bit microcomputer named as SAP-III computer. The CPU of this computer is upward compatible with 8085 microprocessor. The programming model or software model of SAP-III computer is given in figure 4.1. It consists of some more registers than SAP-II computers. In addition to Accumulator (A), B and C registers it contains four more 8-bit registers named as D, E, H and L registers. Because of these registers the flexibility in programming is much more. With special instructions the registers B, C, D, E, H and L may be used as extended register pairs B-C register pair, D-E register pair and H-L register pair, so that 16-bit data may be operated with these registers. It has 16-bit Program counter and 16-bit Stack pointer. The stack pointer is used for stack purposes which will be discussed later in this chapter.

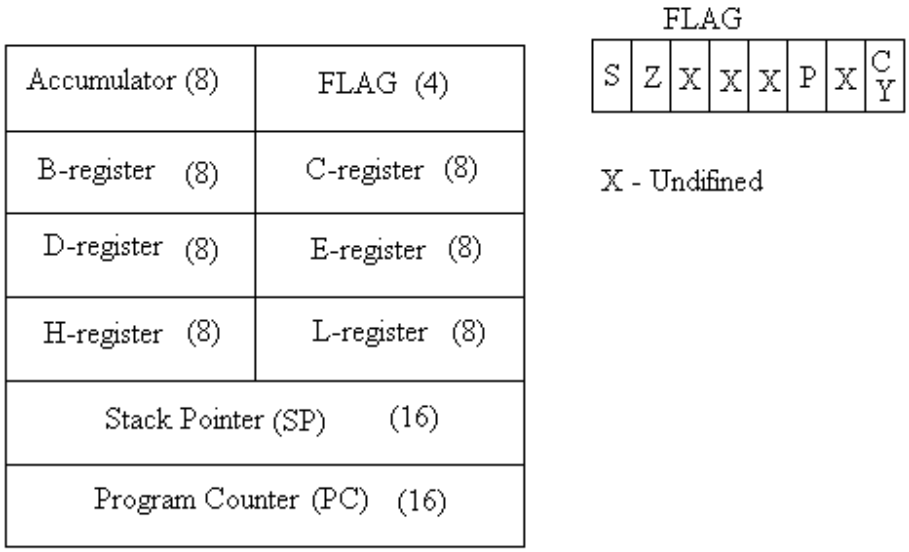

Fig. 4.1

SAP-III computer has a four-bit flag register associated with Accumulator. The four flags are Sign flag (S), Zero flag (Z), Carry flag (CY) and Parity flag (P).

Sign Flag (S)

The sign flag is set (S = 1), if accumulator content is negative and it is reset (S = 0) if accumulator content is positive. The logic circuit is the same as discussed for SAP-II computers.

Zero Flag (Z)

The zero flag is set (Z = 1), if accumulator content is zero and it is reset (Z = 0) if accumulator content is not zero. The logic circuit is the same as discussed for SAP-II computers.

Carry Flag (CY)

The carry flag (CY) is used to detect overflow in some arithmetic and logic operations. In SAP-III computer, the accumulator of CPU is only 8-bit wide. The unsigned binary numbers from 0 to 255 or signed numbers (2's complement) from – 128 to +127 can be the content of the accumulator. The arithmetic operations addition and subtraction are performed using 2's complement adder / subtractor circuit. The logic circuit diagram of such a 2's complement adder / subtractor is shown in figure 4.2.

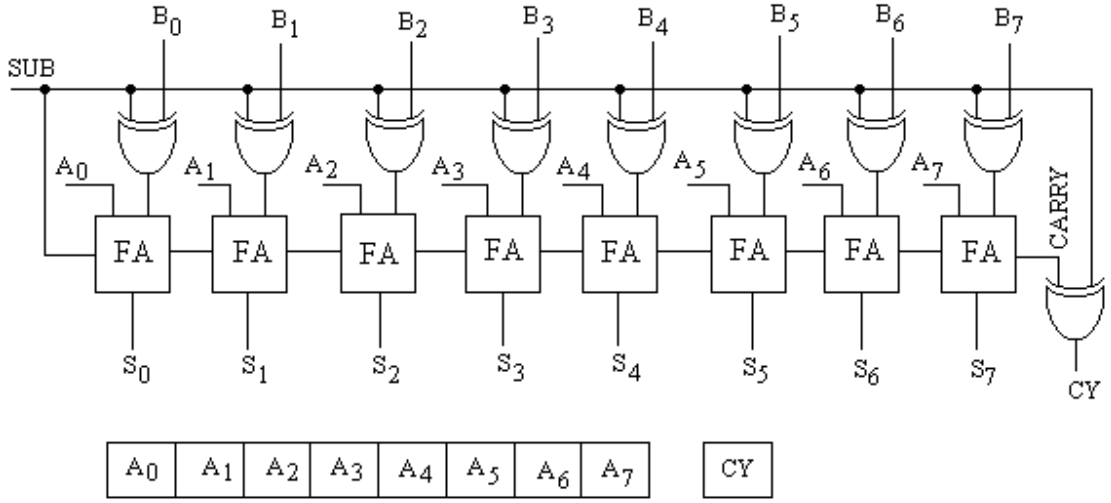

Fig. 4.2

In this circuit one input of each of the exclusive – OR gates are connected to common terminal named as SUB; this common terminal is also connected to carry bit of first full adder. During the addition, SUB terminal is kept low and for subtraction it is kept high. The working of this circuit may be described as given below.

The accumulator content directly goes to full adders. The content, which is to be added to or subtracted from the accumulator content is applied to full adders through the exclusive OR gates. SUB terminal being low during the addition, so the exclusive-OR gates send directly the addend to the full adders. The full adders add the two contents. If there is any overflow, CARRY becomes high which finally sets CY flag. If on the other hand there is no overflow, CARRY is low and CY flag is reset.

So CY = 1, if there is carry and CY = 0, if there is no carry.

Similarly, during subtraction SUB = 1 and the exclusive OR gates converts the subtrahend to its equivalent 1's complement. Since SUB terminal (SUB = 1) is connected to first full adder so 1's complement of the subtrahend gets converted to its equivalent 2's complement. For subtraction, 2's complement of the subtrahend is added with the

accumulator content. If the CARRY signal is high (CARRY = 1), there is an end around carry (EAC), the final exclusive OR gate gives CY = 0 indicating there is no borrow. On the other hand, if there is no CARRY (CARRY = 0 or no EAC), carry flag CY will be set (CY = 1) indicating that there is borrow.

So CY = 0 (Carry flag is restet) there is no carry or borrow.

CY = 1 (Carry flag is set) there is carry or borrow.

The carry flag acts as carry bit for addition and it works as borrow bit for subtraction.

Parity Flag (P)

In addition to sign, carry and zero flags there is also a parity flag. The parity flag is set if there are even number of 1's in the accumulator and it is reset if there are odd number of 1's.

So P = 1 for even parity

and P = 0 for odd parity.

The logic circuit diagram of the parity bit generator for showing the correct parity is shown in figure 4.3.

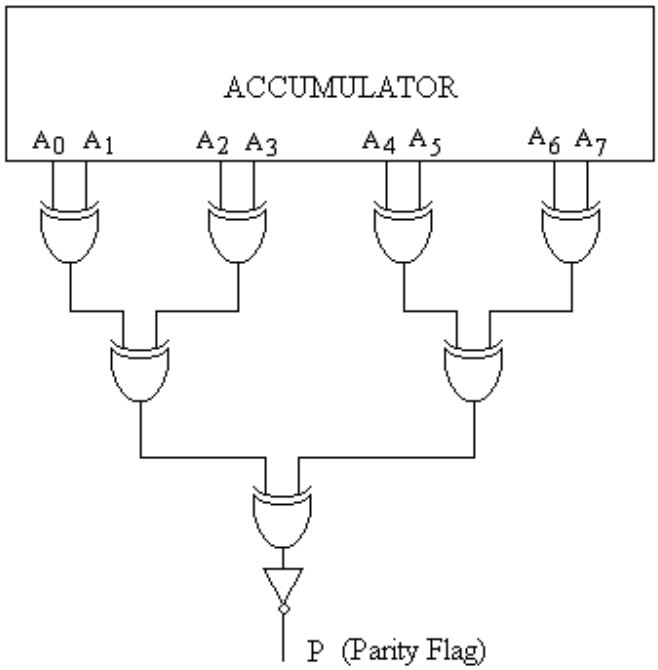

Fig. 4.3

4.2 INSTRUCTION SET OF SAP-III COMPUTER

All the instructions which have been discussed in SAP-II computers are also used in SAP-III computers. In addition to these instructions there are many more instructions which will be discussed here.

The instruction set of SAP-III computers has been classified into following groups.

1. Data Transfer Group
2. Arithmetic Group
3. Branch Group
4. Stack, Input/Output and Machine Control Group

4.2.1 Data Transfer Group

The function of data transfer group of instructions is to transfer the data from register to register, register to memory and also immediate transfer of data (given) to memory location. This group of instruction is also there in SAP-II computers but in SAP-III computers more instruction are there due to more registers. Data transfer group of instructions are given in table 4.1.

These data transfer instructions can further be subdivided on the basis of modes of addressing i.e. direct, immediate and register addressing.

Table 4.1

Data Transfer Group

Instruction	Op. Code	Addressing modes	No of T-states	No of bytes of instr.	Flags affected	Operation
LDA address	3A	Direct	13	3	None	$[A] \leftarrow [M_{address}]$
STA address	32	Direct	13	3	None	$[M_{address}] \leftarrow [A]$
MOV A, A	7F	Register	4	1	None	$[A] \leftarrow [A]$
MOV A, B	78	Register	4	1	None	$[A] \leftarrow [B]$
MOV A, C	79	Register	4	1	None	$[A] \leftarrow [C]$
MOV A, D	7A	Register	4	1	None	$[A] \leftarrow [D]$
MOV A, E	7B	Register	4	1	None	$[A] \leftarrow [E]$
MOV A, H	7C	Register	4	1	None	$[A] \leftarrow [H]$
MOV A, L	7D	Register	4	1	None	$[A] \leftarrow [L]$
MOV B, A	47	Register	4	1	None	$[B] \leftarrow [A]$
MOV B, B	40	Register	4	1	None	$[B] \leftarrow [B]$
MOV B, C	41	Register	4	1	None	$[B] \leftarrow [C]$
MOV B, D	42	Register	4	1	None	$[B] \leftarrow [D]$
MOV B, E	43	Register	4	1	None	$[B] \leftarrow [E]$
MOV B, H	44	Register	4	1	None	$[B] \leftarrow [H]$
MOV B, L	45	Register	4	1	None	$[B] \leftarrow [L]$
MOV C, A	4F	Register	4	1	None	$[C] \leftarrow [A]$
MOV C, B	48	Register	4	1	None	$[C] \leftarrow [B]$
MOV C, C	49	Register	4	1	None	$[C] \leftarrow [C]$
MOV C, D	4A	Register	4	1	None	$[C] \leftarrow [D]$
MOV C, E	4B	Register	4	1	None	$[C] \leftarrow [E]$
MOV C, H	4C	Register	4	1	None	$[C] \leftarrow [H]$
MOV C, L	4D	Register	4	1	None	$[C] \leftarrow [L]$
MOV D, A	57	Register	4	1	None	$[D] \leftarrow [A]$
MOV D, B	50	Register	4	1	None	$[D] \leftarrow [B]$

MOV D, C	51	Register	4	1	None	$[D] \leftarrow [C]$
MOV D, D	52	Register	4	1	None	$[D] \leftarrow [D]$
MOV D, E	53	Register	4	1	None	$[D] \leftarrow [E]$
MOV D, H	54	Register	4	1	None	$[D] \leftarrow [H]$
MOV D, L	55	Register	4	1	None	$[D] \leftarrow [L]$
MOV E, A	5F	Register	4	1	None	$[E] \leftarrow [A]$
MOV E, B	58	Register	4	1	None	$[E] \leftarrow [B]$
MOV E, C	59	Register	4	1	None	$[E] \leftarrow [C]$

MVI M, data	36	Immediate	10	2	None	$[M_{H-L}] \leftarrow data$

(a) Direct Data Transfer Instructions

There is basically two direct data transfer instructions for SAP-III computers which are the same used in SAP-II computers. These are:

(i) LDA address

This is mnemonic for **Loads the accumulator direct**. It transfers the content stored in the addressed memory location (given by address) to accumulator.

$$[A] \leftarrow [M_{address}]$$

No flag is affected in this instruction. It is three byte instruction.

For example if 2AH data is stored in memory location 2500H before the execution of LDA 2500H instruction, then after the execution of this instruction, the data 2AH will be transferred to accumulator.

i.e. $[A] \leftarrow 2A$

(ii) STA address

This is mnemonic for **Stores the accumulator direct**. It transfers the content stored in the accumulator to addressed memory location (given by address).

$$[M_{address}] \leftarrow [A]$$

No flag is affected in this instruction. It is also three byte instruction.

For example if 16H data is stored in the accumulator before the execution of STA 2100H instruction, then after the execution of this instruction, the data 16H will be transferred to the addressed memory location.

i.e. $[M_{2100}] \leftarrow 16$

(b) Register Data Transfer Instructions

These instructions transfer 8-bit data stored in one register to other register. The registers in SAP-III computer are A, B, C, D, E, H and L so the data stored in one of these registers may be transferred to other register. The format for this data transfer instruction is given as:

MOV **reg1, reg2** (**Move Register)**

where *reg1 = A, B, C, D, E, H or L*
reg2 = A, B, C, D, E, H or L

This instruction copies (transfers) the content stored in reg2 to reg1.

$$[reg1] \leftarrow [reg2]$$

Following are the possible combinations of MOV instruction.

MOV A, A	*MOV B, A*
MOV A, B	*MOV B, B*
MOV A, C	*MOV B, C*
MOV A, D	*MOV B, D*
MOV A, E	*MOV B, E*
MOV A, H	*MOV B, H*
MOV A, L	*MOV B, L*
MOV C, A	*MOV D, A*
MOV C, B	*MOV D, B*
MOV C, C	*MOV D, C*
MOV C, D	*MOV D, D*
MOV C, E	*MOV D, E*
MOV C, H	*MOV D, H*
MOV C, L	*MOV D, L*
MOV E, A	*MOV H, A*
MOV E, B	*MOV H, B*
MOV E, C	*MOV H, C*
MOV E, D	*MOV H, D*
MOV E, E	*MOV H, E*
MOV E, H	*MOV H, H*
MOV E, L	*MOV H, L*
MOV L, A	
MOV L, B	
MOV L, C	
MOV L, D	
MOV L, E	
MOV L, H	
MOV L, L	

These instructions are of one byte instruction and no flag is affected in these instructions.

For example if L = 23 H before the execution of instruction *MOV* C, L then after the execution of this instruction 23 H data in register L will be transferred to register C.

i.e. $[L] \leftarrow 23H$

(c) Register Indirect Data Transfer Instructions

In SAP-III computers, there are some register indirect data transfer instructions in which H-L register pair acts like 'data pointer'. The data pointer is represented by M which denotes the memory location whose address is given in the H-L register pair. It is basically represented by M_{HL}.

For example H L = 2500 H then $M \Rightarrow M_{HL}$ represents the memory location whose address is 2500 H. It indicates the memory location M_{2500}.

The instructions related to register immediate data transfer are given as:

(i) *MOV* ***reg, M*** **(Moves register from memory)**

where *reg = A, B, C, D, E, H or L*

This instruction is indirect read instruction. It moves / copies the data stored in memory location whose address is given in H-L register pair, to the given register.

i.e.

$$[reg] \leftarrow [M_{HL}]$$

The possible combinations of this instruction are:

MOV A, M
MOV B, M
MOV C, M
MOV D, M
MOV E, M
MOV H, M
MOV L, M

For example consider 12H data is stored in the memory location whose address is given in H-L register pair (i.e. H-L = 2500H). After the execution of the instruction *MOV B, M* the data 12H will be stored in B register.

$$[B] \leftarrow 12$$

These are one byte instruction and no flag is affected in these instructions.

(ii) *MOV* ***M, reg*** **(Moves memory from register)**

where *reg = A, B, C, D, E, H or L*

This instruction moves / copies the data in the given register to the memory location addressed by H-L register pair.

i.e.

$$[M_{HL}] \leftarrow [reg]$$

It performs reverse work of *MOV reg, M* instruction. The possible combinations of this instruction are:

MOV M, A
MOV M, B
MOV M, C
MOV M, D
MOV M, E
MOV M, H

MOV M, L

For example let D = 4E H H = 23 H L = 00 H

Then after execution of the instruction *MOV M, D* will produce the result:

$$[M_{2300}] \leftarrow 4E$$

These are also one byte instructions and no flag is affected in these instructions.

(d) Immediate Data Transfer Instructions

The format for immediate data transfer instructions is

*MVI **reg, data*** **(Move Immediate)**

where *reg = A, B, C, D, E, H, L orM*

This instruction transfers the given data to the register (reg).

$$[reg] \leftarrow data$$

The possible combinations of move immediate instruction are given below:

MVI A, data
MVI B, data
MVI C, data
MVI D, data
MVI E, data
MVI H, data
MVI L, data
MVI M, data

For example

MVI E, 1AH

means the given data 1AH will be copied into the register E.

$$[E] \leftarrow 1A$$

Also *MVI M, 2BH*

means the given data 2BH will be copied into the memory location whose address is given in H-L register pair. If H = 21 H L = 00 H then

$$[M_{2100}] \leftarrow 2B$$

All these instructions are two byte instructions and no flag is affected.

4.2.2 Arithmetic Group of Instructions

This group of instructions (given in table 4.2) includes the instructions for addition and subtraction. Some of these instructions are the same as discussed in SAP-II computer.

Table 4.2

Arithmetic Group

Instruction	Op. Code	Addressing modes	No of T-States	No of bytes of instr.	Flags affected	Operation
ADD A	87	Register	4	1	All	$[A] \leftarrow [A]+[A]$

RAR	1F	---	4	1	CY	Rotate all right

(a) Add instructions

Following are the add instructions:

(i) *ADD reg* **(Add register)**

where *reg = A, B, C, D, E, H or L.*

It adds the content stored in given register with the accumulator. The result of this addition is stored in accumulator.

$$[A] \leftarrow [A] + [reg]$$

All the flags are affected with this '*ADD reg'* instruction.

The possible combinations of this instruction are as given below:

ADD A
ADD B
ADD C
ADD D
ADD E
ADD H
ADD L

Suppose before the execution of the instruction *ADD E*

A = 10101111
E = 10110101
$CY = 0$, $S = 1$, $Z = 0$ and $P = 1$

then after the execution of the instruction *ADD E* we get the following result:

```
A =        1  0  1  0  1  1  1  1
E =        1  0  1  1  0  1  0  1
           ------------------------
A =   1    0  1  1  0  0  1  0  0
      CY
```

The flags will be affected as;

$CY = 1$, $S = 0$, $Z = 0$ and $P = 0$

$CY = 1$ Since there is a final carry.
$S = 0$ Since Acc content is positive as MSB is zero.
$Z = 0$ Since Acc content is non zero.
$P = 0$ Since Acc content has odd parity.

(ii) *ADD M* **(Add Memory)**

This instruction is one byte instruction and adds the content of memory location whose address is given in H-L register pair with the accumulator and the answer is stored in accumulator.

$$[A] \leftarrow [A] + [M_{HL}]$$

In this instruction too all flags are affected. This instruction is similar to *ADD reg*. For example let A = 40 H H = 21 H L = 00 H

and $M_{2100} = 3AH$

Then after execution of the instruction *ADD M* will produce the result:

A = 7A H

All flag will, however, be affected as per the instruction.

(iii) *ADI data* **(Adds immediately the data)**

It immediately adds the given data with the accumulator and the answer will be stored in Accumulator.

$$[A] \leftarrow [A] + data$$

This is a two-byte instruction. All flags will be affected with this instruction similar to *ADD reg* instruction.

(iv) *ADC* instructions

The format for ADC instruction is

ADC reg **(Add with carry)**

where *reg = A, B, C, D, E, H or L.*

It adds the content stored in given register and content of CY flag with the content of accumulator. The result of this addition is stored in accumulator.

$$[A] \leftarrow [A] + [reg] + [CY]$$

All the flags are affected with this '*ADC reg'* instruction.

The possible combinations of this instruction are as given below:

ADC A
ADC B
ADC C
ADC D
ADC E
ADC H
ADC L

Suppose before the execution of the instruction *ADC D*

A = 10101001
D = 10111101
$CY = 1, \quad S = 1, \quad Z = 0$ and $P = 1$

then after the execution of the instruction *ADD D* we get the following result:

```
CY =                        1
 A =        1  0  1  0  1  0  0  1
 D =        1  0  1  1  1  1  0  1
            ------------------------
 A =   1    0  1  1  0  0  1  1  1
       CY
```

All flags will be affected.

(v) *ADC M* **(Add Memory with Carry)**

This instruction is one byte instruction and adds the content of memory location whose address is given in H-L register pair to the accumulator with carry and the answer is stored in accumulator.

$$[A] \leftarrow [A] + [M_{HL}] + \text{CY}$$

In this instruction too all flags are affected. This instruction is similar to *ADD reg*. For example let A = 50 H CY = 1 H = 25 H L = 00 H

and $M_{2500} = 3BH$

Then after execution of the instruction *ADC M* will produce the result:

A = 8C H

All flag will, however, be affected as per the result.

(vi) *ACI data* **(Adds immediately the data with Carry)**

It immediately adds the given data to the accumulator with carry and the answer will be stored in Accumulator.

$$[A] \leftarrow [A] + data + \text{CY}$$

This is a two-byte instruction. All flags will be affected with this instruction.

(vii) DAD Instruction

The format for this instruction is

DAD rp **(Double Add)**

where rp stands for register pair. It may be B, D or H.
rp as B represents B-C register pair,
rp as D represents D-E register pair,
rp as H represents H-L register pair.

This instruction adds the contents of given register pair with the contents of H-L register pair. The answer will be stored in H-L register pair.

$$[HL] \leftarrow [HL] + [rp]$$

This instruction has the following combinations:

DAD B	$[HL] \leftarrow [HL] + [BC]$
DAD D	$[HL] \leftarrow [HL] + [DE]$
DAD H	$[HL] \leftarrow [HL] + [HL]$

For example before the execution of the instruction DAD D, we have the following data in different registers.

DE = 2AB6 H
HL = 012 7 H

After the execution of this instruction we HL = 2BDD H

Only carry flag will be affected in this instruction.

(b) Subtract Instructions

Following are the subtract instructions:

(i) *SUB reg* **(Subtract Register)**

where *reg = A, B, C, D, E, H or L.*

It subtracts the contents stored in given register from the accumulator. The result of this subtraction is stored in accumulator.

$$[A] \leftarrow [A] - [reg]$$

All the flags are affected with this '*SUB reg*' instruction.

The possible combinations of this instruction are as given below:

SUB A
SUB B
SUB C
SUB D
SUB E
SUB H
SUB L

Suppose before the execution of the instruction *SUB D*

A = 10101111

D = 10110101

$CY = 0$, $S = 1$, $Z = 0$ and $P = 1$

then after the execution of the instruction $SUB\,D$ we get the following result:

A = 1 0 1 0 1 1 1 1

D = 1 0 1 1 0 1 0 1

A = 1 1 1 1 1 1 0 1 0

CY

All flags will be affected as per the accumulator contents.

(ii) *SUB M* **(Subtract Memory)**

This instruction is one byte instruction and subtracts the contents of memory location whose address is given in H-L register pair from the accumulator and the answer is stored in accumulator.

$$[A] \leftarrow [A] - [M_{HL}]$$

In this instruction too all flags are affected.

For example let A = 56 H H = 22 H L = 01 H

and $M_{2201} = 2CH$

Then after execution of the instruction *SUB M* will produce the result:

A = 2A H

All flag will however be affected as per the instruction.

(iii) *SUI data* **(Subtracts immediately the data)**

It immediately subtracts the given data with the accumulator contents and the answer will be stored in Accumulator.

$$[A] \leftarrow [A] - data$$

This is a two-byte instruction. All flags will be affected with this instruction.

(iv) *SBB reg* **(Subtract with Borrow)**

where *reg = A, B, C, D, E, H or L.*

This instruction subtracts the contents stored in given register from the accumulator with borrow. The answer will be stored in accumulator.

$$[A] \leftarrow [A] - [reg] - [CY]$$

All the flags are affected in the operation of this instruction.

The possible combinations of this instruction are as given below:

SBB A
SBB B
SBB C
SBB D
SBB E
SBB H
SBB L

Suppose before the execution of the instruction $SBB\,H$

A = 10101111

H = 10110101

$CY = 0$, $S = 1$, $Z = 0$ and $P = 1$

then after the execution of the instruction $SUB\,H$ we get the following result:

A = 1 0 1 0 1 1 1 1

H = 1 0 1 1 0 1 0 1
CY = 1

A = 1 1 1 1 1 1 0 0 1
CY

All flags will be affected as per the accumulator contents.

(v) *SBB M* **(Subtract memory with Borrow)**

Similar to *SBB reg*, this instruction subtracts the content already stored in memory location addressed by H-L register pair with borrow bit (carry flag) from the accumulator contents and the answer is stored in accumulator.

$$[A] \leftarrow [A] - [M_{HL}] - [CY]$$

All flags will be affected as per the accumulator contents.

(vi) *SBI data* **(Subtract immediate with Borrow)**

SBI data instruction subtracts the given data with borrow bit (carry flag) from the accumulator contents and it stores the answer in accumulator.

$$[A] \leftarrow [A] - data - [CY]$$

All flags will be affected as per the accumulator contents.

(c) Increment Instructions

The increment instructions used in SAP-III computer are given below:

(i) *INR reg* **(Increment Register)**

where *reg = A, B, C, D, E, H or L.*

It increments the contents of given register by one and answer is stored in the given register.

$$[reg] \leftarrow [reg] + 1$$

The possible combinations of this instruction are:

INR A
INR B
INR C
INR D
INR E
INR H
INR L

These instructions do not affect the CY flag but affect all other flags.

For example if Z = 0, S = 1, and CY = 0 and contents of register is

C = 1 1 1 1 1 1 1 1 , then after the execution of the instruction INR C we have:

C = 0 0 0 0 0 0 0 0

Z = 1, S = 0, and CY = 0

(ii) *INR M* **(Increment Memory)**

It increments the contents of memory location addressed by H-L register pair by 1 and stores the answer in the addressed memory location.

$$[M_{HL}] \leftarrow [M_{HL}] + 1$$

Similar to *INR reg*, all flags except carry flag will be affected after the execution of this instruction.

(iii) *INX rp* **(Increment register pair)**

where *rp* is the register pair as B-C register pair, D-E register pair and H-L register pair. This instruction increments the contents given in register pair by one and the result is stored in the given register pair.

$$[rp] \leftarrow [rp] + 1$$

The possible combinations of this instruction are:

INX B
INX D
INX H

No flag is affected with the execution of this instruction.

For example if H = FF H and L = FF H CY = 1, Z = 0

After the execution of the instruction INX H, we have the contents in H-L pair as: H = 25 H and L = 01 H ; the contents of the flags will not be affected. So the carry and zero flag will have the same value as having before the execution of this instruction i.e. CY = 1, Z = 0

(d) Decrement Instructions

The decrement instructions used in SAP-III computer are given below:

(i) DC*R reg* (Decrement Register)

where *reg = A, B, C, D, E, H or L.*

It decrements the contents of given register by one and answer is stored in the given register.

$$[reg] \leftarrow [reg] - 1$$

The possible combinations of this instruction are:

DCR A
DCR B
DCR C
DCR D
DCR E
DCR H
DCR L

These instructions do not affect the CY flag but affect all other flags.

For example if Z = 0, S = 1, and CY = 0 and contents of D register is

D = 0 0 0 0 0 0 0 0 , then after the execution of the instruction DCR D we have:

C = 1 1 1 1 1 1 1 1

Z = 0, S = 1, and CY = 0

(ii) *DCR M* (Decrement Memory)

It decrements the contents of memory location addressed by H-L register pair by 1 and stores the answer in the addressed memory location.

$$[M_{HL}] \leftarrow [M_{HL}] - 1$$

Similar to *DCR reg*, all flags except carry flag will be affected after the execution of this instruction.

(iii) *DCX rp* (Increment register pair)

where *rp* is the register pair as B-C register pair, D-E register pair and H-L register pair. This instruction decrements the contents given in register pair by one and the result is stored in the given register pair.

$$[rp] \leftarrow [rp] - 1$$

The possible combinations of this instruction are:

DCX B
DCX D
DCX H

No flag will be affected with the execution of this instruction like INX rp.

For example if D = 23 H and E = 00 H

After the execution of the instruction DCX D, we have the contents in D-E pair as: D = 22 H and E = FF H

(e) Rotate Instructions

In rotate instructions, the accumulator contents are shifted either left or right. In some instructions shifting may be through CY flag or without CY flag. Following are the rotate instructions.

(i) *RLC* **(Rotate Accumulator Left)**

In this instruction, the bits of the accumulator contents are shifted or rotated left. The LSB of the accumulator is changed as MSB (before the execution). The CY flag is modified as MSB (before the execution).

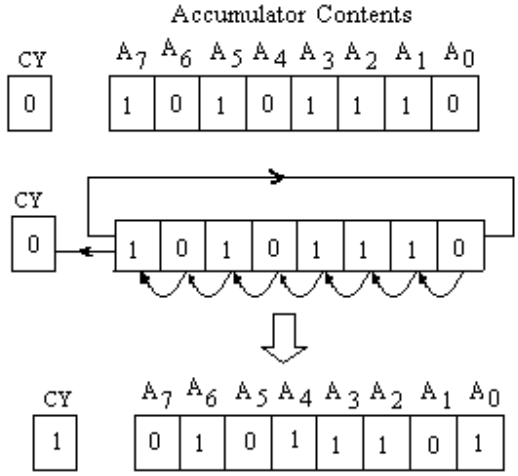

Fig. 4.4

For example A = AE H and CY = 0, before the execution of the instruction RLC. After the execution of the instruction MSB is saved in CY flag and also in the LSB of the accumulator. The other bits are shifted left as shown in figure 4.4.

i.e. $[A_{n+1}] \leftarrow [A_n]$

$[A_0] \leftarrow [A_7]$ also $[CY] \leftarrow [A_7]$

Only carry flag CY will be affected in this instruction and all other flags will be unaffected.

(ii) *RAL* **(Rotate Accumulator Left Through Carry)**

In this instruction, the bits of the accumulator contents will be shifted / rotated left through carry. The content of carry flag CY will be stored in LSB of the accumulator and MSB of the accumulator will be stored in CY flag. All other bits of the accumulator will be shifted to the left.

For example if A = 6A H and CY = 1 before the execution of RAL instruction, then after the execution of this instruction the accumulator contents will be shifted as shown in figure 4.5.

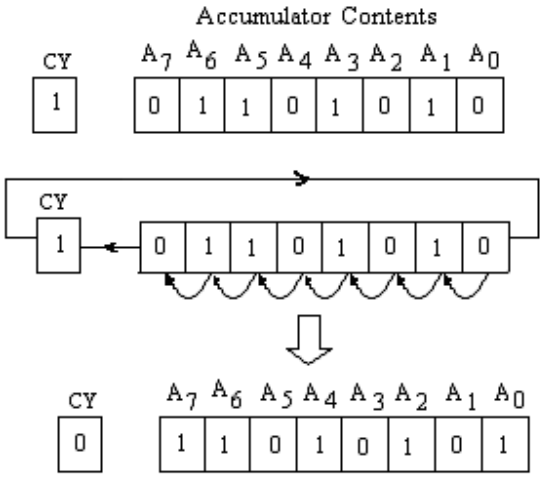

Fig. 4.5

In this instruction too only carry flag will be affected.

(iii) *RRC* **(Rotate Accumulator Right)**

In this instruction, all the bits of accumulator are shifted or rotated right. The MSB of the accumulator is changed as LSB (before the execution). The CY flag is modified as MSB (before the execution).

For example $A = 93$ H and $CY = 0$, before the execution of the instruction RRC. After the execution of this instruction LSB is saved in CY flag and also in the MSB of the accumulator. The other bits are shifted left as shown in figure 4.6.

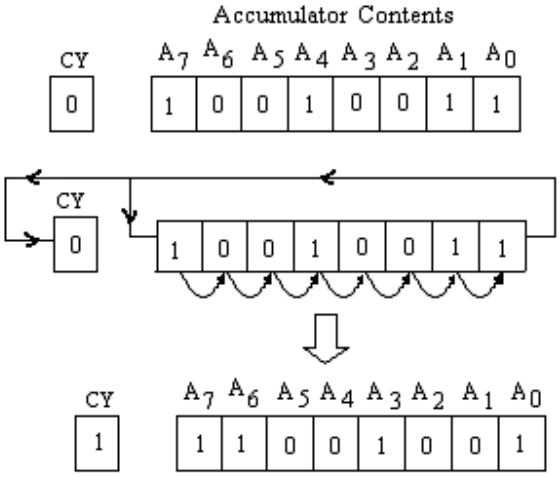

Fig. 4.6

In this instruction only carry flag CY will be affected and all other flags will be unaffected.

(iv)*RAR* **(Rotate Accumulator Right Through Carry)**

In this rotate instruction, all the bits of the accumulator contents will be shifted / rotated right through carry. The content of carry flag CY will be stored in MSB of the accumulator and LSB of the accumulator will be stored in CY flag; and all other bits of the accumulator will be shifted to the right.

For example if A = 76 H and CY = 1 before the execution of RAR instruction, then after the execution of this instruction the accumulator contents will be shifted as shown in figure 4.7.

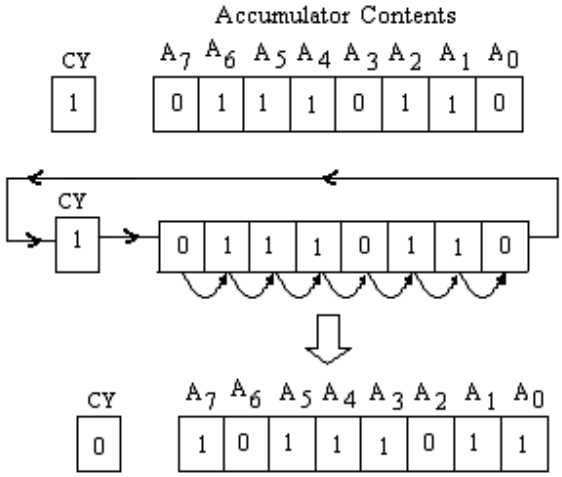

Fig. 4.7

In this instruction too only carry flag will be affected.

4.2.3 Logic Transfer Group

The logic group of instructions operates on registers, memory and conditional flags. This group of instructions contains ANDing, ORing, XORing, complementing and comparing of data (table 4.3).

Table 4.3

Logic Transfer Group

Instruction	Op. Code	Addressing modes	No of T-states	No of bytes of instr.	Flags affected	Operation
ANA A	A7	Register	4	1	All (CY=0)	$[A] \leftarrow [A].AND.[A]$
ANA B	A0	Register	4	1	All (CY=0)	$[A] \leftarrow [A].AND.[B]$
ANA C	A1	Register	4	1	All (CY=0)	$[A] \leftarrow [A].AND.[C]$
ANA D	A2	Register	4	1	All (CY=0)	$[A] \leftarrow [A].AND.[D]$
ANA E	A3	Register	4	1	All (CY=0)	$[A] \leftarrow [A].AND.[E]$
ANA H	A4	Register	4	1	All (CY=0)	$[A] \leftarrow [A].AND.[H]$
ANA L	A5	Register	4	1	All (CY=0)	$[A] \leftarrow [A].AND.[L]$
ANA M	A6	Register Indirect	7	1	All (CY=0)	$[A] \leftarrow [A].AND.[M_{H-L}]$
ANI data	E6	Immediate	7	2	All (CY=0)	$[A] \leftarrow [A].AND.data$

ORA A	B7	Register	4	1	All (CY=0)	$[A] \leftarrow [A].OR.[A]$
ORA B	B0	Register	4	1	All (CY=0)	$[A] \leftarrow [A].OR.[B]$
ORA C	B1	Register	4	1	All (CY=0)	$[A] \leftarrow [A].OR.[C]$
ORA D	B2	Register	4	1	All (CY=0)	$[A] \leftarrow [A].OR.[D]$
ORA E	B3	Register	4	1	All (CY=0)	$[A] \leftarrow [A].OR.[E]$
ORA H	B4	Register	4	1	All (CY=0)	$[A] \leftarrow [A].OR.[H]$
ORA L	B5	Register	4	1	All	$[A] \leftarrow [A].OR.[L]$
ORA M	B6	Register Indirect	7	1	All (CY=0)	$[A] \leftarrow [A].OR.[M_{H-L}]$
ORI data	F6	Immediate	7	2	All (CY=0)	$[A] \leftarrow [A].OR.data$
XRA A	AF	Register	4	1	All (CY=0)	$[A] \leftarrow [A] \oplus [A]$
XRA B	A8	Register	4	1	All (CY=0)	$[A] \leftarrow [A] \oplus [B]$
XRA C	A9	Register	4	1	All (CY=0)	$[A] \leftarrow [A] \oplus [C]$
XRA D	AA	Register	4	1	All (CY=0)	$[A] \leftarrow [A] \oplus [D]$
XRA E	AB	Register	4	1	All (CY=0)	$[A] \leftarrow [A] \oplus [E]$
XRA H	AC	Register	4	1	All (CY=0)	$[A] \leftarrow [A] \oplus .[H]$
XRA L	AD	Register	4	1	All (CY=0)	$[A] \leftarrow [A] \oplus [L]$
XRA M	AE	Register Indirect	7	1	All (CY=0)	$[A] \leftarrow [A] \oplus [M_{H-L}]$
XRI data	EE	Immediate	7	2	All (CY=0)	$[A] \leftarrow [A] \oplus data$
CMP A	BF	Register	4	1	All	
CMP B	B8	Register	4	1	All	
CMP C	B9	Register	4	1	All	
CMP D	BA	Register	4	1	All	
CMP E	BB	Register	4	1	All	
CMP H	BC	Register	4	1	All	
CMP L	BD	Register	4	1	All	
CMP M	BE	Register Indirect	7	1	All	
CPI data	FE	Immediate	7	2	All	

CMA	2F	---	4	1	None	$[A] \leftarrow [\overline{A}]$
CMC	3F	---	4	1	CY	$CY \leftarrow \overline{CY}$
STC	37	---	4	1	CY	$CY \leftarrow 1$

The details of these instructions are given below:

(a) Logical Instructions

(i) ***ANA reg*** **(AND register)**

where *reg = A, B, C, D, E, H or L.*

In this instruction each bit of the given register contents are ANDed with each bit of the accumulator contents (bit by bit). The result is saved in the accumulator. It does not affect the contents of the given register.

$$[A] \leftarrow [A].AND.[reg]$$

The possible combinations of this instruction are:

AND A
ANA B
ANA C
ANA D
ANA E
ANA H
ANA L

The *ANA reg* instruction clears (resets) the CY flag and all other flags are modified according to the data conditions of the result. This instruction is one byte instruction.

Let A = 73 H C = C3 H CY = 1

before the execution of the instruction *ANA C*. Then after the instruction is executed we get:

A = 0 1 1 1 0 0 1 1 CY = 1

C = 1 1 0 0 0 0 1 1

A = 0 1 0 0 0 0 1 1 CY = 0

(ii) ***ANA M*** **(AND Memory)**

In this instruction each bit of the data stored in the memory location addressed by H-L register pair are ANDed with each bit of the accumulator contents (bit by bit). The result is stored in the accumulator like *ANA reg*.

$$[A] \leftarrow [A].AND.[M_{H-L}]$$

Similar to ANA reg instruction data of the memory location addressed by H-L register pair will not be affected; the carry flag will, however, be reset after the execution of this instruction and other flags will be affected as per the data in the accumulator.

Let A = 19 H H = 25 H L = 00 H

$M_{2500} = 37$ H and CY = 1

before the execution of the instruction *ANA M*. Then after the instruction is executed we get:

A = 0 0 0 1 1 0 0 1 CY = 1

M_{2500} = 0 0 1 1 0 1 1 1

A = 0 0 0 1 0 0 0 1 CY = 0

(iii) *ANI data* **(AND Immediate)**

In this instruction each bit of the given data is immediately ANDed with each bit of the accumulator contents (bit by bit). The result is stored in the accumulator. The difference between *ANA reg* and *ANI data* instruction is that in *ANA reg* the data given in the register where as in the *ANI data* instruction, the data is given with the instruction itself.

$$[A] \leftarrow [A].AND.data$$

The carry flag will be reset after the execution of this instruction and other flags will be affected as per the result.

For example, if A = AB H and CY = 1 before the execution of ANI 06 H, then after the execution of this instruction we have:

A = 1 0 1 0 1 0 1 1 CY = 1

data = 0 0 0 0 0 1 1 0

A = 0 0 0 0 0 0 1 0 CY = 0

(iv) *ORA reg* **(OR register)**

where *reg = A, B, C, D, E, H or L.*

In this instruction each bit of the given register contents are ORed with each bit of the accumulator contents (bit by bit). The result is saved in the accumulator. It does not affect the contents of the given register.

$$[A] \leftarrow [A].OR.[reg]$$

The possible combinations of this instruction are:

ORA A
ORA B
ORA C
ORA D
ORA E
ORA H
ORA L

The *ORA reg* instruction clears (resets) the CY flag and all other flags are modified according to the data conditions of the result. This instruction is one byte instruction.

Let A = 73 H C = C3 H CY = 1

before the execution of the instruction *ORA B*. Then after the instruction is executed we get:

A = 0 1 1 1 0 0 1 1 CY = 1

B = 1 1 0 0 0 0 1 1

A = 1 1 1 1 0 0 1 1 CY = 0

(v) *ORA M* **(OR Memory)**

In this instruction each bit of the data stored in the memory location addressed by H-L register pair are ORed with each bit of the accumulator contents (bit by bit). The result is stored in the accumulator.

$$[A] \leftarrow [A].OR.[M_{H-L}]$$

Similar to *ORA reg* instruction data of the memory location addressed by H-L register pair will not be affected; the carry flag will however be reset after the execution of this instruction and other flags will be affected as per the data in the accumulator.

Let A = 19 H H = 21 H L = 00 H

$M_{2100} = 37$ H and CY = 1

before the execution of the instruction *ORA M*. Then after the instruction is executed we get:

A = 0 0 0 1 1 0 0 1 CY = 1

M_{2100} = 0 0 1 1 0 1 1 1

A = 0 0 1 1 1 1 1 1 CY = 0

(vi) *ORI data* **(OR Immediate)**

In this instruction each bit of the given data is immediately ORed with each bit of the accumulator contents (bit by bit). The result is stored in the accumulator.

$$[A] \leftarrow [A].OR.data$$

The carry flag will be reset after the execution of this instruction and other flags will be affected as per the result.

For example, if A = AB H and CY = 1 before the execution of ANI 16 H, then after the execution of this instruction we have:

A = 1 0 1 0 1 0 1 1 CY = 1

data = 0 0 0 1 0 1 1 0

A = 1 0 1 1 1 1 1 1 CY = 0

(vii) *XRA reg* **(Exclusive OR register)**

where *reg = A, B, C, D, E, H or L.*

In this instruction each bit of the given register contents are *XORed* with each bit of the accumulator contents (bit by bit). The result is saved in the accumulator. It does not affect the contents of the given register.

$$[A] \leftarrow [A].XOR.[reg]$$

The possible combinations of this instruction are:

XRA A
XRA B
XRA C
XRA D
XRA E
XRA H
XRA L

The *XRA reg* instruction clears (resets) the CY flag and all other flags are modified according to the data conditions of the result. This instruction is one byte instruction.

Let A = 73 H D = C3 H CY = 1

before the execution of the instruction *XRA D*. Then after the instruction is executed we get:

A = 0 1 1 1 0 0 1 1 CY = 1

D = 1 1 0 0 0 0 1 1

A = 1 0 1 1 0 0 0 0 CY = 0

(viii) *XRA M* **(Exclusive OR Memory)**

In this instruction each bit of the memory location addressed by H-L register pair are XORed with each bit of the accumulator contents (bit by bit). The result is stored in the accumulator.

$$[A] \leftarrow [A].XOR.[M_{H-L}]$$

The carry flag will be reset after the execution of this instruction and other flags will be affected as per the data in the accumulator.

Let A = 19 H H = 22 H L = 00 H

$M_{2200} = 37$ H and CY = 1

before the execution of the instruction *ORA M*. Then after the instruction is executed we get:

A = 0 0 0 1 1 0 0 1 CY = 1

M_{2200} = 0 0 1 1 0 1 1 1

A = 0 0 1 0 1 1 1 0 CY = 0

(ix) *XRI data* **(Exclusive OR Immediate)**

In this instruction each bit of the given data is immediately XORed with each bit of the accumulator contents (bit by bit). The result is stored in the accumulator.

$$[A] \leftarrow [A].XOR.data$$

The carry flag will be reset after the execution of this instruction and other flags will be affected as per the result.

For example, if A = AB H and CY = 1 before the execution of ANI 12 H, then after the execution of this instruction we have:

A = 1 0 1 0 1 0 1 1 CY = 1

data = 0 0 0 1 0 0 1 0

A = 1 0 1 1 1 0 0 1 CY = 0

(x) *CMA* **(Complement Accumulator)**

This is one byte implied addressing instruction as no operand is required with the instruction. The execution of this instruction inverts each bit of the accumulator contents and the result is saved in the accumulator. Basically it produces 1's complement of the accumulator contents. No flag is affected with this instruction.

$$[A] \leftarrow [\overline{A}]$$

For example, if A = 0B H before the execution of *CMA* instruction, then after the execution of this instruction we have:

A = 0 0 0 0 1 0 1 1

= 1 1 1 1 0 1 0 0

A = 1 1 1 1 0 1 0 0 (F4)

(b) Compare Instructions

(i) *CMP reg* (Compare Register)

The contents of the given register are compared with the accumulator contents. In fact the contents of the register are subtracted from the contents of accumulator and the accumulator contents remain unchanged. However, as a result of the subtraction the flags are modified as per the result.

The zero flag Z is set if $[A] = [reg]$ otherwise reset. Similarly, carry flag CY is set if $[A] < [reg]$ otherwise reset.

The possible combinations of *CMP reg* are given below:

CMP A
CMP B
CMP C
CMP D
CMP E
CMP H
CMP L

To illustrate the above instruction let us consider the following assembly language program.

Label	**Mnemonics**	**Operand**
	MVI B,	00 H
	MVI A,	09 H
LOOP	INR B	
	CMP B	
	JNZ	LOOP

In this program before the loop A = 09 H and B = 00 H. The value of B will increase by each go in the loop and each time it is compared with accumulator contents. Till the contents of B register are not equal to the contents of Accumulator, the computer will execute the instructions inside the loop. When the value of B register becomes equal to 09 H, the zero flag will be set and it will allow coming out of the loop to execute the next instructions.

(ii) *CMP M* (Compare Memory)

It is similar to *CMP reg* instruction with the difference that the contents of the addressed memory location will be compared by the accumulator contents. The flags will be modified as per the result.

(iii) CPI data **(Compare immediate with data)**

It is similar to CMP instruction with the difference that the data is directly given with the instruction. In this instruction the given data is compared with the accumulator contents. The flags will be modified as per the result.

(c) Miscellaneous Logical Instructions

(i) *CMC* **(Complement the carry)**

This instruction complements the carry flag.

$$CY \leftarrow \overline{CY}$$

If CY = 1 before the execution of *CMC* instruction, the carry flag will be reset (CY = 0) after the execution of this instruction. Similarly, If CY = 0 before the execution of *CMC* instruction, the carry flag will be set (CY = 1) after the execution of this instruction.

In this only carry flag will be affected and all other flags will not be affected.

(ii) *STC* **(Set the carry)**

It sets the carry flag.

$$CY \leftarrow 1$$

The carry flag will be set (CY = 1) irrespective of the carry flag is set or reset before the execution of this instruction *STC*.

Only carry flag gets affected with this instruction.

4.2.4 Branch Group

This group of instructions changes the normal sequence of the program. The branch instructions include JUMP, CALL and RETURN instructions, which are further sub-divided as unconditional and conditional JUMP, CALL and RETURN instructions.

Table 4.4

Branch Group

Instruction	Op. Code	Addressing modes	No of T-states	No of bytes of instr.	Flags affected	Operation
JMP addr	C3	Immediate	10	3	None	$[PC] \leftarrow [addr]$
JNZ addr	C2	Immediate	10/7	3	None	$[PC] \leftarrow [addr]$ if Z=0.
JZ addr	CA	Immediate	10/7	3	None	$[PC] \leftarrow [addr]$ if Z=1.
JNC addr	D2	Immediate	10/7	3	None	$[PC] \leftarrow [addr]$ if CY=0.
JC addr	DA	Immediate	10/7	3	None	$[PC] \leftarrow [addr]$ if CY=1.
JM addr	FA	Immediate	10/7	3	None	$[PC] \leftarrow [addr]$ if S=1.
JP addr	F2	Immediate	10/7	3	None	$[PC] \leftarrow [addr]$ if S=0.
JPO addr	E2	Immediate	10/7	3	None	$[PC] \leftarrow [addr]$ if P=0.
JPE addr	EA	Immediate	10/7	3	None	$[PC] \leftarrow [addr]$ if P=1.
CALL addr	CD	Immediate	18	3	None	Calls subroutine program.

CNZ addr	C4	Immediate	18/9	3	None	Calls subroutine program if Z=1.
CZ addr	CC	Immediate	18/9	3	None	Calls subroutine program if Z=0.

CPE addr	EC	Immediate	18/9	3	None	Calls subroutine program if P=1.
RNZ	C0	Register indirect	12/6	1	None	Returns to main program if Z=1.
RZ	C8	Register indirect	12/6	1	None	Returns to main program if Z=0.
RNC	D0	Register indirect	12/6	1	None	Returns to main program if CY=0.
RC	D8	Register indirect	12/6	1	None	Returns to main program if CY=1.
RM	F8	Register indirect	12/6	1	None	Returns to main program if S=1.
RP	F0	Register indirect	12/6	1	None	Returns to main program if S=0.
RPO	E0	Register indirect	12/6	1	None	Returns to main program if P=0.
RPE	E8	Register indirect	12/6	1	None	Returns to main program if P=1.

(a) Unconditional Jump Instructions

(i) *JMP address* (label) (Jump to Address)

This is an unconditional jump instruction. With the execution of this instruction, the program jump to the address (or label) specified with the instruction. This is a three byte instruction and no flag is affected. In fact during the execution of *JMP address* (label) instruction, the address of the label is copied in the program counter; and whenever the program fetches the next instruction the program counter will send the address of this given label.

$$[PC] \leftarrow [LABEL]$$

(a) Conditional Jump Instructions

In conditional jump instructions the program jumps to the instructions specified by the address (or label) if the given condition is fulfilled. However, if the given condition is not satisfied, the program will not jump to the specified address (or label)

rather it will proceed to the normal sequence. In all these conditional jump instructions, if program jumps to the specified address after the given condition is satisfied, it will take 10 T-states for its execution otherwise it takes 7 T-states.

Following are the conditional Jump instructions. Some of them have also been used in SAP-II computers.

(i) *JNZ address* (label) (Jump if the result is not zero)

When this instruction is executed, the program jumps to the instruction specified by the address (or label), if the result is not zero; otherwise it will proceed to the next instruction. Here the result of the preceding instruction is considered.

In this case the address (or label) is copied in the program counter if zero flag is reset (Z = 0).

$$[PC] \leftarrow LABEL \text{ if } Z = 0.$$

This is illustrated if we consider the following instructions:

Label	Mnemonics	Operand

	DCR	C
	JNZ	NEXT
	MOV A, M	
NEXT	STA	2500 H
	HLT	

For the execution of JNZ instruction, the result of C-register will be considered. If $[C] \neq 0$ (Z = 0), it will jump to the instruction (*STA 2500 H*) specified by the label NEXT, otherwise it will jump to the next instruction (*MOV A, M*).

(ii) *JZ address* (label) (Jump if the result is zero)

The condition of this instruction is reverse to that of *JNZ address*. In this case the program will jump to the instruction specified by the address (or label), if the result of the preceding instruction is zero (Z = 1) otherwise it will proceed to the next instruction in the normal sequence.

The address of the label will be copied in the program counter if Z flag is set (or result is zero).

$$[PC] \leftarrow LABEL \text{ if } Z = 1.$$

(iii)*JNC address* (label) (Jump if no carry)

During the execution of this instruction, it will check up the Carry flag modified by the preceding instruction. If there is no carry (CY = 0 or CY flag is reset), the program will jump to the instruction specified by the address (or label) otherwise it will proceed to the next instruction of the normal sequence.

In this case the address of the label will be copied in the program counter if CY = 0 or CY is reset.

$$[PC] \leftarrow LABEL \text{ , if } CY = 0$$

(iv) *JC address* (label) (Jump if carry)

The program will jump to the instruction specified by the address (label) if the CY flag is set (CY = 1) which is modified by the preceding instruction. However, if the carry

is reset (CY = 0), it will proceed to the next instruction of the normal sequence. The condition of this instruction is opposite to that of the *JNC address*.

In this case the address of the label will be copied in the program counter if CY = 1 or CY is set.

$$[PC] \leftarrow LABEL \text{ , if CY = 1}$$

(v) *JM address* (label) (Jump if Minus)

When this instruction is executed, the program will jump to the instruction specified by the address (label) if the result of the preceding instruction is minus or sign flag is set (S = 1) otherwise it will proceed to the next instruction of the normal sequence.

$$[PC] \leftarrow LABEL \text{ , if S = 1}$$

(vi) *JP address* (label) (Jump if Positive)

If the result of the preceding instruction is positive or sign flag is reset (S = 0), the program will jump to the instruction specified by the address (label). However, if the condition is not satisfied it will proceed to the next instruction of the normal sequence.

$$[PC] \leftarrow LABEL \text{ , if S = 0}$$

(vii) *JPO address* (label) (Jump if Parity is Odd)

If the parity is odd or parity flag is reset (P = 0) as a result of the preceding instruction, the program will jump to the instruction specified by the address (label) otherwise next instruction of the normal sequence will be executed.

$$[PC] \leftarrow LABEL \text{ , if P = 0}$$

(vii) *JPE address* (label) (Jump if Parity is Even)

If the parity is even or parity flag is set (P = 1) as a result of the preceding instruction, the program will jump to the instruction specified by the address (label) otherwise next instruction of the normal sequence will be executed.

$$[PC] \leftarrow LABEL \text{ , if P = 1}$$

(c) CALL Instructions

The call instructions allow calling the subroutine program. The address of the subroutine program is specified with the CALL instruction. During the execution of CALL instruction, the current contents of program counter are saved on the stack and the address of subroutine (specified with the CALL instruction) is copied in the program counter. Like the jump instructions, the CALL instructions are also of two types.

1. Unconditional Call Instructions
2. Conditional Call Instructions

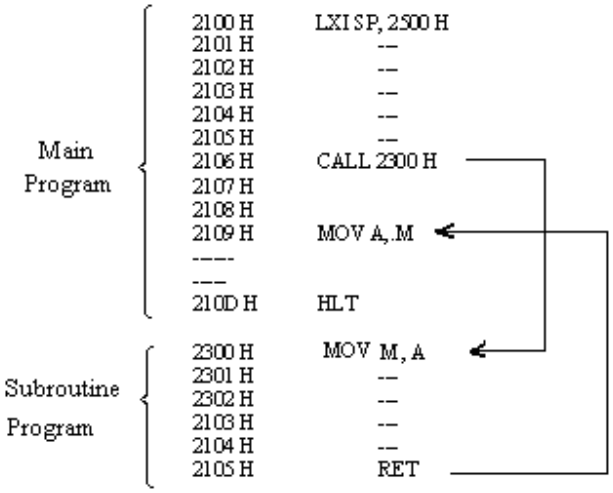
1. Unconditional Call Instructions

CALL address **(Calls the addressed subroutine program)**

This is the format for unconditional call instruction which is of three bytes. The current contents of program counter are saved on the Stack and the address specified with CALL instruction is copied in the program counter.

i.e.
$$[SP-1] \leftarrow [PCH]$$
$$[SP-2] \leftarrow [PCL]$$
and
$$[PC] \leftarrow address$$

To illustrate the CALL address instruction, consider the following assembly language program:



In this program *LXI SP, 2500 H* initializes the stack pointer (stack pointer is represented by 2500 H.) i.e. the area or memory locations less than 2500 H will be used for stack purposes. When the instruction *CALL 2300 H* is executed, the address of the program counter will be 2109 H. The address of the program counter will be saved on the stack. For this stack pointer will be decremented by 1 and the high byte of the program counter (21 H) will be saved on to it; the stack pointer will further be decremented by 1 and lower byte of the program counter (09 H) will be stored on to it. The decremented of the stack pointer will be current position of the stack. This is shown in figure 4.8.

The address given with the CALL instruction i.e. 2300 H will be saved or copied in the program counter.

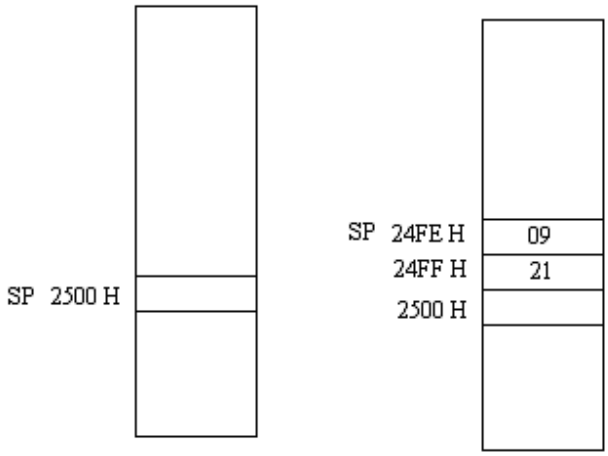


Fig. 4.8

The subroutine program ends at the instruction RET i.e. RET instruction will be the last instruction of the subroutine program. The RET instruction takes the computer back to the main program. The return saved (or pushed) on to the stack will be popped back to the program counter. Further the data stored (or saved) at the top of the stack will be copied as the lower byte of the program counter i.e. $[PCL] \leftarrow [M_{SP}]$. The program

counter will now be incremented by one and data stored in new stack will be saved to higher byte of the program counter i.e. $[PCH] \leftarrow [M_{SP+1}]$.

In the above program, after the execution of RET instruction **PC = 2109 H**.

2. Conditional Call Instructions

Similar to conditional jump instruction SAP-III computer has the following conditional instructions.

(i) CNZ address **(Call if not zero)**

This instruction will call the subroutine program specified by the address provided the zero flag is reset.

i.e. if Z = 0 or the result is not zero then

$$[SP-1] \leftarrow [PCH]$$
$$[SP-2] \leftarrow [PCL]$$
and $$[PC] \leftarrow address$$

(ii) CZ address **(Call if zero)**

It will call the subroutine (specified by the address) if zero fags is set.

i.e. if Z = 1 or the result is 1 zero then

$$[SP-1] \leftarrow [PCH]$$
$$[SP-2] \leftarrow [PCL]$$
and $$[PC] \leftarrow address$$

(iii) CNC address **(Call if no carry)**

This instruction will check the carry flag. If the carry flag is reset (or CY=0) as per the executed preceding instruction, then the computer will call the addressed subroutine program.

i.e. if CY = 0 or there is no carry, then

$$[SP-1] \leftarrow [PCH]$$
$$[SP-2] \leftarrow [PCL]$$
and $$[PC] \leftarrow address$$

(iv) CC address **(Call if carry)**

The addressed subroutine will be called by the computer, there is a carry (or carry flag is set ; CY = 1) as per the result of the preceding instruction.

i.e. if CY = 1 or there is a carry, then

$$[SP-1] \leftarrow [PCH]$$
$$[SP-2] \leftarrow [PCL]$$
and $$[PC] \leftarrow address$$

(v) CM address **(Call if minus)**

During the execution of this instruction the sign flag will be checked. If the result of the preceding instruction is negative or sign flag is set (S = 1), then only the computer will call the subroutine program specified by the address.

So if S = 1, then

$$[SP-1] \leftarrow [PCH]$$
$$[SP-2] \leftarrow [PCL]$$
and $$[PC] \leftarrow address$$

(vi) CP address **(Call if positive)**

In this CALL instruction too the sign flag will be checked. If the result of the preceding instruction is positive or sign flag is reset (S = 0), then the computer will call the subroutine program specified by the address.

So if S = 0, then

$$[SP-1] \leftarrow [PCH]$$
$$[SP-2] \leftarrow [PCL]$$
and $$[PC] \leftarrow address$$

(vii) CPO address **(Call if parity is odd)**

If the parity of the result of the preceding instruction is odd (or parity flag is reset; P = 0), then the computer will call the addressed subroutine program.

So if P = 0, then

$$[SP-1] \leftarrow [PCH]$$
$$[SP-2] \leftarrow [PCL]$$
and $$[PC] \leftarrow address$$

(ix) CPE address **(Call if parity is even)**

The computer will call the addressed subroutine program, if the parity of the result of the preceding instruction is even (or parity flag is set; P = 1), then.

So if P = 0, then

$$[SP-1] \leftarrow [PCH]$$
$$[SP-2] \leftarrow [PCL]$$
and $$[PC] \leftarrow address$$

Return Instructions

As already discussed, the last instruction of the subroutine program is RET (Return instruction). This return instruction takes the computer back to the main program. The return instructions may also be conditional. The following are the conditional return instructions:

RNZ	**Return if no zero**
RZ	**Return if zero**
RNC	**Return if no carry**
RC	**Return if carry**
RM	**Return if minus**
RP	**Return if positive**
RPO	**Return parity is odd**
RPE	**Return parity is even**

All the above return instructions are one byte instructions. If the specified condition is satisfied, it will return to the main program; otherwise the execution of the next instruction in the subroutine will be carried out. Further the return instruction will pop the return address to the program counter.

For example, we consider the instruction ***RNC.***

It will check the carry flag. Only if the carry flag is reset (CY = 0 or no carry), the computer return to main program.

i.e. if CY = 0 , then

$$[PCL] \leftarrow [SP]$$
$$[PCH] \leftarrow [SP+1]$$

4.2.5 Stack and Input / Output Instructions

Stack is a portion of read/write memory, which is primarily used for saving return address and data. As discussed earlier, in SAP-II computers, last two memory locations of the read / write memory FFFF H and FFFE H are exclusively used for return address of a subroutine call. In SAP-III computers, the programmer can specify any area of the memory for the stack purposes. The portion of memory located chosen by the programmer for the stack purposes can not be used for saving the return address of subroutine call. For this purpose a 16 bit register called stack pointer is provided.

Table 4.5

Stack I/O Group

Instruction	Op. Code	Addressing modes	No of T-States	No of bytes of instr.	Flags affected	Operation
LXI SP, addr	31	Immediate	10	3	None	
PUSH B	C5	Register indirect	12	1	None	
PUSH D	D5	Register indirect	12	1	None	
PUSH H	E5	Register indirect	12	1	None	
PUSH PSW	F5	Register indirect	12	1	None	
POP B	C1	Register indirect	10	1	None	
POP D	D1	Register indirect	10	1	None	
POP H	E1	Register indirect	10	1	None	
POP PSW	F1	Register indirect	10	1	None	
IN Port	DB	Immediate	10	2	None	
OUT Port	D3	Immediate	10	2	None	

The stack is initialized by the instruction given below:

LXI SP, address **(Load immediately the stack pointer)**

For example *LXI SP, 2500* H will indicate the stack pointer as 2500 H as

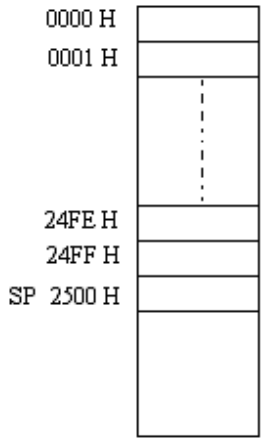

Fig. 4.9

shown in figure 4.9. So the memory locations lower than 2500 H may be used for stack purposes i.e. the data or return addresses may be pushed to stack in the sequence discussed earlier in CALL instructions.

Following are the Stack instructions:

(i) Push Instructions

In the stack not only the return address of the main program during the execution of CALL address instruction is pushed but also the contents of registers may also be pushed to stack. For this following is the format of PUSH instructions:

PUSH rp

where rp stands for register pair. It may be
B for B-C register pair,
D for D-E register pair,
H for H-L register pair,
PSW is known as program status word; it represents the accumulator and the flag contents i.e. **A F**

So we have the following PUSH instructions.

```
PUSH B      ; it pushes or saves the contents of B
              and C registers on the stack.
PUSH D      ; it pushes or saves the contents of D
              and E registers on the stack.

PUSH H      ; it pushes or saves the contents of H
              and L registers on the stack.

PUSH PSW    ; it pushes or saves the contents of
              accumulator (A) and F (flag)
              registers on the stack.
```

Following steps are carried out during the execution of ***PUSH rp*** instructions.

1. The stack pointer is decremented by one to get a new value of stack pointer as SP-1.

2. The contents of higher register of the given register pair (say B register in B-C register pair.

   i.e. $[M_{SP-1}] \leftarrow [rp_H]$

3. The stack pointer is further decremented by one to get new value of stack pointer as SP-2.
4. The contents of lower register (C register in B-C register pair) is saved in the memory location specified by SP-2.

   i.e. $[M_{SP-2}] \leftarrow [rp_L]$

5. SP-2 will now be the stack pointer for other PUSH instructions.

For example we have SP = 2500 H
HL = 5678 H

After the execution of PUSH H instruction 56 H will be loaded to memory location 24FF H and 78 H will be loaded to 24FE H memory location as shown in figure 4.10.

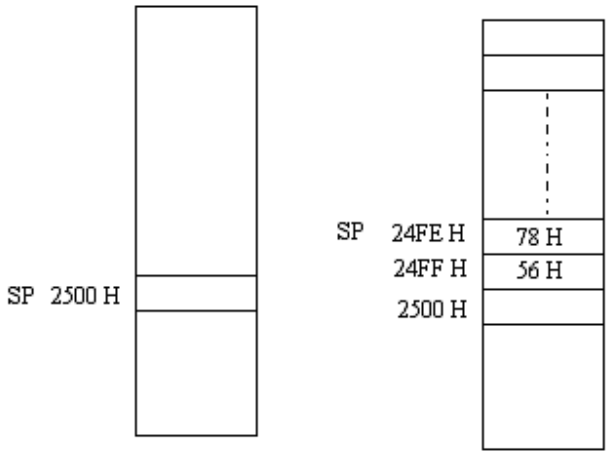

Fig. 4.10

(ii) Pop Instructions

To retrieve the contents of registers from the stack, following POP instructions are used.

POP B	; where B stands for B-C register pair.
POP D	; where D stands for D-E register pair.
POP H	; where H stands for H-L register pair.
POP PSW	; where PSW stands for Program status word i.e. accumulator (A) and F (flag) register.

During the execution of POP instructions following steps are carried out.

1. The byte stored in memory location addressed by stack pointer is saved in the lower register of the given register pair (say C in B-C register pair). The contents of higher register of the given register pair (say B register in B-C register pair.
   i.e. $[rp_L] \leftarrow [M_{SP}]$
2. The stack pointer is incremented by one to get new value of stack pointer as SP+1.
3. The contents stored in the memory location addressed by stack pointer (new value as SP+1) is saved in higher register of the given register pair (B register in B-C register pair).
   i.e. $[rp_H] \leftarrow [M_{SP+1}]$
4. The stack pointer is further incremented by one to get the new value of stack pointer as SP+2 i.e. SP+2 will now work as stack pointer.

Suppose the data saved in stack is shown in figure 4.11. The stack pointer is shown as 24FC H.

Let A = 01 H F = 00 H
D = 12 H E = 6E H

before the execution of

POP PSW

and POP D instructions.

After the execution of these instructions we have the following data in the registers.

F = 59 H
A = 24 H
E = 36 H
D = 9F H

Now 2500 H will be the new value of stack pointer.

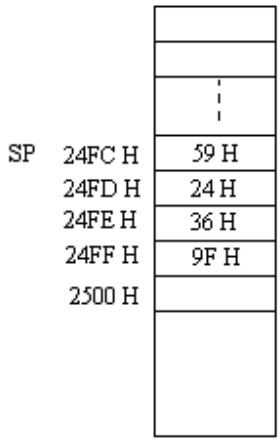

Fig. 4.11

It should be remembered that when a subroutine is called, it should save the contents of any register being used in the main program using PUSH instruction in the stack; and when it returns back to the main program form the subroutine program the

contents of the register should be retrieved from the stack using POP instruction as discussed above.

The sequence of PUSH and POP instructions should be as:

```
PUSH  PSW
PUSH  D
PUSH  B
PUSH  H
----------
----------
POP  H
POP  B
POP  D
POP PSW
```

It should be noted that POP retrieve the data from the stack just in reverse order of the data was PUSHed i.e. as Last In First Out (LIFO) method is used in the stack.

PUSH and POP instructions may also be used in the main program. PUSH instruction is used before the CALL instruction and POP (in the reverse order) after the CALL instruction in the main program as given below:

Main Program:

```
----------
----------
PUSH  PSW
PUSH  H
CALL  LABEL
POP  H
POP PSW
-----------
------------
```

In this program the contents of Accumulator, Flag, H and L registers are saved in the Stack before the execution of CALL instruction. After the execution of subroutine program the contents of the Accumulator, Flag, H and L registers are retrieved and next instructions of the main program will be executed with restoration of earlier values of the registers.

Further, the PUSH and POP instructions may be used in the subroutine program as given below. This is generally done when the CALL instruction is used may times.

Main Program:

```
----------
----------
CALL  LABEL
-----------
-----------
```

Subroutine Progam:

```
LABEL    PUSH  PSW
         PUSH  D
         PUSH  B
         ----------
         ----------
         POP  B
         POP  D
         POP  PSW
         RET
```

Input / Output Instructions

The input / output instructions deal with the input / output operations. These instructions are same used in SAP-II computer.

(i) IN Port **(Inputs the data from the port)**

In this instruction the data available at the specified port address is moved to the accumulator.

$$[A] \leftarrow \textit{data from port}$$

It is two byte instruction and no flag is affected after the execution of this instruction. This instruction is basically used to read the data from the input devices such as data read from key board, switches etc. during the computer run.

(ii) OUT Port **(Outputs the data to the port)**

This two byte output instruction is used to send the contents of accumulator to the specified port.

$$\textit{Output} \leftarrow [A]$$

4.3 TIME DELAY INTRODUCED BY A REGISTER PAIR

The time delay introduced by different registers has been discussed in the last chapter using SAP-II instructions. The time delay can considerably be increased by using a register pair. A 16-bit number may be taken in two registers (register pair).

Consider the following subroutine assembly language program:

Label	Mnemonics	Operand	Comments
	LXI D,	F424 H	;Loads DE register pair with a 16-bit number.
LOOP	DCX	D	;Decrements DE register pair by one.
	MOV A,	E	;Moves the contents of E register to accumulator.
	ORA	D	;ORing of the contents of D and E registers are performed to set the zero flag.
	JNZ	LOOP	;If result $\neq 0$ jump to loop
	RET		;Go back to main program.

Total T-states used for the above program are given as:

Mnemonics	T-states
LXI	10
DCX	5
MOV	5
ORA	4
JNZ LOOP	10/7
RET	10

24 T-states are used for the inner loop and 10+7+10 = 27 T-states are used for outer loop.

In this program the execution of loop is for 62500 times (as F424 H = 62500_{10}). The condition for the check of zero flag can not be applied just after DCX instruction, since no flag gets affected with this instruction. So to check the zero flag ORA instruction affect the zero flag. The zero flag will be set if the contents of both D and E registers are zero.

The time delay introduced by the inner loop is:

$$T_{LOOP} = 62500 \text{ x } 24 \text{ x Time of one T-state.}$$

If the system clock frequency is 3 MHz, then

$$T_{LOOP} = 62500 \text{ x } 24 \text{ x } \frac{1}{3}\mu\text{sec}$$
$$= 500000\ \mu\text{sec}$$
$$= 0.5 \text{ sec.}$$

Delay introduced for outside loop is:

$$T_{out} = 27\text{x}1\text{x}\frac{1}{3}\mu\text{sec}$$
$$= 9\ \mu\text{sec}$$

So the total time delay introduced by the above subroutine program is given by:

$$T_{Delay} = 0.5 \text{ sec} + 9\ \mu\text{sec}$$
$$\approx 0.5 \text{ sec}$$

Example 4.1 *What maximum delay can be introduced by the subroutine program using a register pair? Let the system clock frequency is 3 MHz.*

Solution. The subroutine program for the delay using a register pair is given as:

Label	Mnemonics	Operand
	LXI D,	FFFF H
LOOP	DCX	D
	MOV	A, E
	ORA	D
	JNZ	LOOP
	RET	

The maximum delay can be introduced if the maximum number (FFFF H) is taken in DE register pair.

FFFF H = 65535_{10}

So $$T_{LOOP} = 65535 \text{ x } 24 \text{ x } \frac{1}{3}\mu\text{sec} + 27\text{x}1\text{x}\frac{1}{3}\mu\text{sec}$$
$$= 524280+9\ \mu\text{sec}$$

= 524289 μsec
= 0.52 sec

Example 4.2 *Write a program in assembly language to introduce a time delay of 1 sec using a register pair. Let the system clock frequency is 3 MHz.*

Solution. For one sec delay, the program discussed in section in 4.3 can be executed twice as given below:

Main Program:

Label	Mnemonics	Operand
	MVI C,	02 H
LOOP1	CALL	DELAY
	DCR	C
	JNZ	LOOP1
	HLT	

Subroutine Program:

Label	Mnemonics	Operand
DELAY	LXI D,	F424 H
LOOP	DCX	D
	MOV	A, E
	ORA	D
	JNZ	LOOP
	RET	

In this program the subroutine program is run two times as subroutine program in one go introduces a time delay of 0.5 sec.

Example 4.3 *It is desired to clear the accumulator contents of a SAP-III computer. Explain the possible instructions for this purpose.*

Solution. To clear the accumulator contents, the possible instructions are:

(i)	MVI A, 00 H	Two byte instruction and no flag gets affected.
(ii)	XRA A	One byte instruction, CY flag will be reset and all other flags will be modified as per the result.
(iii)	ANI 00 H	Two byte instruction, CY flag will be reset and all other flags will be modified as per the result.
(iv)	SUB A	One byte instruction and all flags will be affected as per the result.

Example 4.4 *Write a program in assembly language using instructions of SAP-III computers to complement the 256 bytes stored in memory locations 2500 H through 25FF H. Store the complemented data in memory locations starting at 2600 H.*

Solution.

Label	Mnemonics	Operand	Comments
	LXI H,	2500 H	;Loads the address of the first number in H-L register pair.
	MVI C,	FF H	; 256 bytes (FF H) is stored in C-register as index register.
LOOP	MOV A,	M	;Moves the contents of memory location addressed

			by H-L register pair to accumulator.
	CMA		;complements the accumulator contents.
	MVI H,	26 H	;Stores 26 H in H-register
	MOV M,	A	;Complemented data is stored in the destination memory location.
	MVI H,	25 H	;Stores 25 H in H-register
	INX H		;Increments the H-L register pair.
	DCR C		;Decrements the contents of C register.
	JNZ	LOOP	;Go back to loop for the operation of next data.
	HLT		

Example 4.5 *Write a program in assembly language using instructions of SAP-III computers to find the smaller of two numbers stored in memory locations 2501 H and 2502 H. Store the result in 2503 H memory location.*

Solution.

Label	Mnemonics	Operand	Comments
	LXI H,	2501 H	;Loads the address of the first number in H-L register pair.
	MOV A,	M	;Saves the first number in accumulator.
	INX H		;Increments the H-L register pair.
	CMP M		;compares the two numbers.
	JC	NEXT	;if carry smaller number is in accumulator go to NEXT.
	MOV A,	M	;If no carry then move the smaller number to accumulator.
NEXT	STA	2503 H	;Stores the smaller number in 2503 memory location .
	HLT		

Example 4.6 *Write a program in assembly language using instructions of SAP-III computers to add two hexadecimal numbers stored in memory locations 2501 H and 2502 H. The answer should be stored in 2503 H memory location. The carry if any should be stored in 2504 H memory location.*

Solution.

Label	Mnemonics	Operand	Comments

```
                LXI  H,     2501 H    ;Loads the address of the
                                       first number in H-L register
                                       pair.
                MVI C,      00 H      ;Clears C-register for carry
                                       (most significant bit).
                MOV  A,     M         ;Saves the first number in
                                       accumulator.
                INX  H                ;Increments the H-L
                                       register pair.
                ADD  M                ;Adds the two numbers.
                JNC         NEXT      ;if no carry go to NEXT.
                INR  C                ;Else increment the content
                                       of C-register.
NEXT            STA         2503 H    ;Stores the answer .
                MOV  A,     C         ;Moves the contents of C
                                       register (carry contents) to
                                       accumulator
                STA         2504 H    ;Saves the contents of
                                       carry.
                HLT
```

Example 4.7 *Write a program in assembly language for SAP-III computers to find the sum of a series 1+2+3+……+10 (or sum of first 10 natural numbers).*

Solution.

```
Label           Mnemonics   Operand   Comments
                MVI B,      01 H      ;Loads first number of series
                                       to B-register.
                MVI C,      00 H      ;Clears C-register.
LOOP            MOV  A,     C         ;Saves the contents of C-
                                       register to accumulator.
                ADD  B                ;Adds the contents of B-
                                       register with the contents of
                                       accumulator.
                MOV  C,     A         ;Saves the partial sum to C-
                                       register.
                INR  B                ;increments the contents of
                                       B-register.
                CPI  0B H             ;Compares with natural
                                       number 11.
                JNZ         LOOP      ;If not 11 go back to LOOP.
                MOV  A,     C         ;Saves the answer to
                                       accumulator.
                STA         2500 H    ;Saves the answer to
                                       memory location.
                HLT
```

Example 4.8 *Reset all the flags, in a subroutine program, without performing arithmetic or logical instructions. However the contents of other registers should not be changed.*

Solution.

Label	Mnemonics	Operand	Comments
	PUSH H		;Saves the contents of H-L register pair to stack.
	PUSH PSW		;Saves the contents of A-F to stack.
	LXI H,	0000 H	;Loads 0000 H to H-L register pair.
	PUSH H		; Saves the contents of H-L register pair to stack.
	POP PSW		;Saves the contents of stack in A-F registers.
	POP H		; Retrieve the contents of H-L register pair from the stack.
	MOV A,	H	;Moves the contents of H-register to accumulator.
	POP H		;Pops the contents from stack to H-L register pair.
	RET		

Example 4.9 *How will you exchange the contents of BC and HL register pairs?*
Solution. Following program may exchange the contents of BC and HL register pairs:

Label	Mnemonics	Operand	Comments
	LXI SP,	XXX H	;Initializes the stack pointer.
	PUSH B		;Saves the contents of B-C register pair to stack.
	PUSH H		;Saves the contents of H-L register pair to stack.
	POP B		;Pops the contents of stack (H-L register pair contents) to B-C register pair.
	POP H		;Pops the contents of stack (B-C register pair contents) to H-L register pair.
	HLT		

Example 4.10 *Write a subroutine program using SAP-III instructions, which will subtract the contents of D-E register pair from H-L register pair and the result is to be stored in H-L register pair.*
Solution.

Label	Mnemonics	Operand	Comments
	MOV A,	L	;Transfer the contents of L register to accumulator.
	SUB E		;Contents of E register are subtracted from accumulator contents.

	MOV L,	A	;Answer (list significant digit of the answer) is loaded to L register.
	MOV A,	H	;Moves the contents of H register to accumulator.
	SBB D		;Subtracts the content of D register from acc. with carry.
	MOV H,	A	;Most significant digit of the answer is saved in H register.
	HLT		

Example 4.11 *What will be the value of accumulator and flags (CY, S, P and Z), after the execution of the following program.*

Label	***Mnemonics***	***Operand***
	MVI D,	*7F H*
	MVI C,	*3E H*
	MOV A,	*C*
	RLC	
	RLC	
	ANA D	
	HLT	

Solution. After the execution of the above program we have:

	D = 0 1 1 1 1 1 1 1	
	C = 0 0 1 1 1 1 1 0	
	A = 0 0 1 1 1 1 1 0	
After first RLC	A = 0 1 1 1 1 1 0 0	CY = 0
After second RLC	A = 1 1 1 1 1 0 0 0	CY = 0
ANDing of D	= 0 1 1 1 1 1 1 1	

The value of accumulator is	A = 0 1 1 1 1 0 0 0 = 78 H	
The values of Flag register are:	CY = 0 (reset after ANDing)	
	S = 0	
	P = 1	
	Z = 0	

Example 4.12 *Write a program using SAP-III instructions to check the even parity or the odd parity of the number stored in memory location 2010 H. Send 00 H or EE H at the output port 02 H if the parity is odd or even respectively.*

Solution.

Label	**Mnemonics**	**Operand**	**Comments**
	LXI H,	2010 H	;Initializes the H-L register pair with the address of the location.
	MOV A,	M	;Moves the number to accumulator.

	ORA A		;ORing of A with A will load the same number to accumulator. The parity flag will be affected with this operation.
	JPO	ODD	;Jump to ODD if parity is odd.
	MVI A,	EE H	;Load EE H to accumulator for even parity.
	OUT	02 H	;EE is sent to output port 02H.
	JMP	END	;Jump to end.
ODD	MVI A,	00 H	;Load 00 H to accumulator for odd parity.
	OUT	02 H	;00 is sent to output port 02H.
END	HLT

	HLT		

(b) *Suggest some alternative program that can perform the same operation.*

Solution. (a) In the beginning accumulator is loaded with a hexadecimal number 07 H.

The instruction *STC* and *CMC* resets the carry flag and RAL instruction moves the accumulator contents left through carry giving us the contents 0E H ($=14_{10}$) i.e. *STC*, *CMC* and *RAL* instructions multiplies the accumulator contents by a factor of two. The accumulator contents are now saved in register B.

Three instructions *STC*, *CMC* and *RAL* are further used twice so that accumulator contents are multiplied by a factor of 4. This way after the third *RAL* in the program we have A = 8 X 07 H = 38 H = 56_{10}.

After *ADD B* we get:

A = 38 H + 0E H
= 46 H
= 70_{10}

So this program multiplies the accumulator contents by a factor of 10 (decimal number) which is stored in B-register.

So B = 46 H

$= 70_{10}$

(b) The program given in (a) multiplies the accumulator contents by a factor of 10 (decimal number) which is stored in B-register. The following program also perform the same operation.

Label	Mnemonics	Operand	Comments
	MVI A,	07 H	;Loads 07 H to accumulator.
	ANI	FF H	;It clears the carry flag.
	RAL		;Shifts left by one bit or multiplies accumulator contents by a factor or two.
	MOV B,	A	;Moves the answer to B-register.
	ANI	FF H	;It clears the carry flag.
	RAL		;Shifts left by one bit or multiplies accumulator contents by a factor or two. So A = 4 x A.
	ANI	FF H	;It again clears the carry flag.
	RAL		;Shifts left by one bit or multiplies accumulator contents by a factor or two. So A = 8 x A.
	ADD B		; $[A] \leftarrow [A] + [B]$ So it gives A = 10 x A
	MOV B,	A	;Result is stored in B register.
	HLT		

This program does the same operation as given in (a), however, less number of instructions is used in this program.

Example 4.14 *A byte of data is stored in memory location 2500 H. Display at the output port 02 H the number of 1's present in the data byte stored in memory location 2500 H.*

Solution.

Label	Mnemonics	Operand	Comments
	LDA	2500 H	;Loads the data byte in accumulator.
	MVI C,	08 H	;08 H is loaded to C-register to use it as a counter.
	MVI B,	00 H	; 00 H is loaded to B-register.
LOOP	RLC		;MSB is shifted to carry flag.
	JNC	NEXT	;Checks the carry flag, if not zero go to next (i.e. no 1 is present at the MSB).
	INR B		;Increments the B-register by one.

```
NEXT    DCR  C          ;Decrements C-register.
        JNZ     LOOP    ;Jumps to LOOP if Z = 0.
        MOV  A, B       ;No. of 1's present is loaded
                        to accumulator.
        OUT     02 H    ;Sends the data to the output
                        port.
        HLT
```

PROBLEMS

1. Give the programming model (Software model) of SAP-III computers.
2. How many flags are used in SAP-III computers? How are these flags affected with the result?
3. Explain with the help of block diagram how the carry flag gets affected with the result.
4. In how many groups the instruction set of SAP-III computers are classified. Explain with examples the instructions of arithmetic group.
5. Discuss the rotate instructions used in SAP-III computers. How the flags are affected with these instructions.
6. What is the difference between the stack and stack pointer? Discuss PUSH and POP instructions.
7. Explain what operations are performed when the following instructions are executed. Give at least one example for each operation.
   (i) LXI H, address
   (ii) ADD M
   (iii) CMP reg
8. What is difference between *CMP reg* and *SUB reg* instructions? Explain with suitable examples.
9. If carry flag is zero, then show that RAL instruction produces a multiplication of accumulator contents by a factor of 2.
10. If carry flag is zero, then show that RAR instruction produces a division of accumulator contents by a factor of 2.
11. Show that the instruction DAD H shifts left the data in H-L register pair by one bit.
12. Discuss various addressing modes of SAP-III computers instructions and give at least two examples of each addressing mode.
13. What do you understand by subroutine? Explain the use of stack and stack pointer in calling a subroutine. Explain any other use of stack.
14. Write a program for SAP-III computers introduce a time delay of 0.5 sec if the system clock frequency is 6 MHz.
15. Explain the following instruction of SAP-III computer. Also discuss which flags get affected with the execution of these instructions.
    ADD M, CMP B, POP PSW and MOV A, M.
16. An *ORA reg* or *ORI data* instruction can be used to make a selected bit of a specified register as 1. Justify this statement. Also write the mnemonic of an instruction that will set bit 6 of the accumulator without changing any of the other bits in the register. **(Ans.: ORI 40 H)**

17. What will be contents of accumulator and flags (CY, S, P and Z), after the execution of ADD D instruction; if A = C3 H and D = 3D H.

(Ans: A= 00 H, CY = 1, S = 0, P = 1 and Z = 1)

18. What will be contents of accumulator and flags (CY, S, P and Z), after the execution of SUB D instruction; if A = C3 H and D = 3D H.

(Ans: A= 85 H, CY = 0, S = 1, P = 0 and Z = 0)

19. What will be contents of memory location 2500 H and flags (CY, S, P and Z), after the execution of the following program:

```
MVI C, C8 H
MVI A, 11 H
ADD C
STA 2500 H
HLT
```

(Ans: M_{2500} = D9 H, CY = 0, S = 1, P = 0 and Z = 0)

20. What will be the value of stack pointer, after the following program written in SAP-III instructions is executed.

```
LXI SP, 27FF H
PUSH D
CALL SUBROUT
POP D
ADD D
PUSH D
HLT
```

What will be the value of stack pointer after this program?

(Ans: SP = 27FD H)

21. What will be the contents in B-register, after the execution of the following assembly language program?

Label	Mnemonics	Operand
	MVI A,	08 H
	STC	
	CMC	
	RAL	
	MOV B,	A
	HLT	

(Ans.: B = 10 H = 16_{10})

5

The 8085 Microprocessor

After the study of conceptual computers SAP-I, SAP-II and SAP-III, we are now in the position to understand the fundamentals of 8-bit microprocessor 8085. As discussed in the preceding chapters, the basic components of all the computers are Keyboard, Display devices, Memory devices and Central Processing unit. The central processing unit (CPU) is the heart of the computer and also called microprocessor.

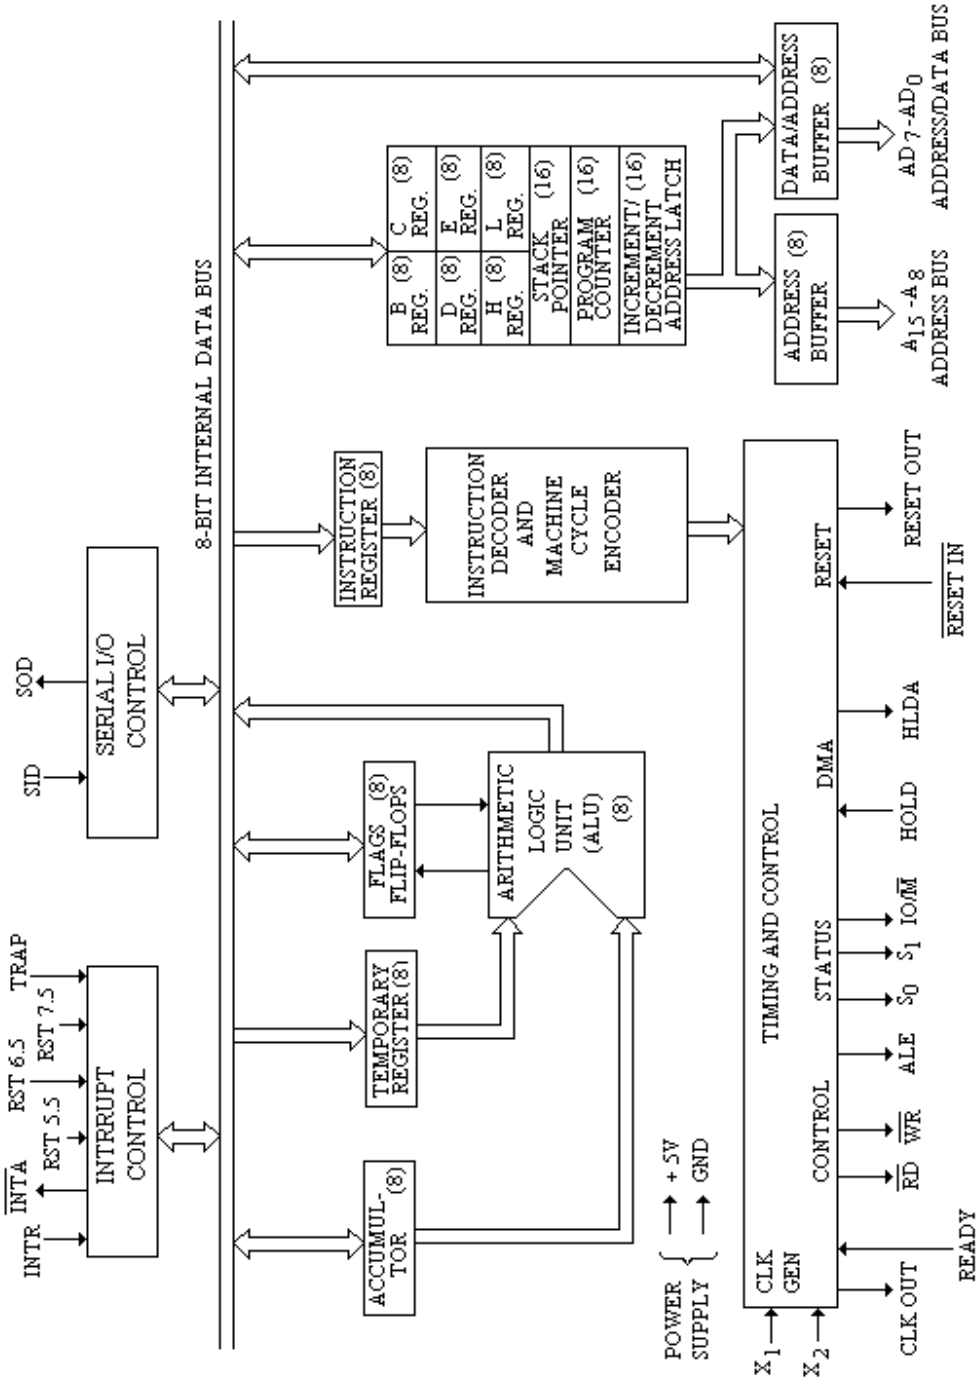
The technological revolution brought in recent years, the invention of micro-programmable computer on microprocessor chip. First four bit microprocessor chip INTEL-4004 was developed by Intel Corporation of America in 1971. Intel introduced in 1972 an 8-bit microprocessor 8008 and in 1973 another 8-bit microprocessor 8080. The microprocessor 8080 was the most popular microprocessor of the early 70s. In the year 1974, Intel developed a 40 pin microprocessor chip 8085, which was the enhanced version of 8080. Intel 8080 microprocessor was not in fact a complete CPU on a chip because the clock and controller were on separate chip. Further, it utilizes two separate power supplies. The 8085 microprocessor has the advantages over 8080 that it has on-chip clock and control circuit. It needs only one power supply of +5 volts.

5.1 ARCHITECTURE OF 8085 MICROPROCESSOR

Intel 8085, an 8-bit NMOS microprocessor is available in the form of 40 Pin dual in line IC package. It is fabricated on a single LSI chip. It operates on +5 V d.c. supply. The clock speed used in this microprocessor is about 3 MHZ. General Purpose 8-bit microprocessor is capable of addressing up to 64 K bytes (i.e. $2^{16} = 65536$ bytes) of memory. The functional block diagram is shown in figure 5.1.

The main functional components of 8085A microprocessor are as given below:

(i) Register Section
(ii) Arithmetic and Logic Unit
(iii) Timing and Control Section
(iv) Interrupt Control
(v) Serial Input / Output Control



8-BIT INTERNAL DATA BUS
SERIAL I/O CONTROL

Fig. 5.1

5.1.1 Register Section

The 8085 microprocessor contains eight addressable 8-bit registers namely:

A (Accumulator) register
F Flag register (Flag flip-flops)
B register
C register
D register
E register
H register
L register

Out of these registers B, C, D, E, H and L registers are 8-bit general purpose registers. These registers can either be used as single register or a combination of two registers as 16 bit register pair. As discussed in SAP-III computers, the valid register pairs are B-C, D-E or H-L register pairs. The higher order byte of 16 bit data is stored in first register (B in B-C register pair), and low order byte in the second register (C in B-C register pair).

The H-L register pair can also be used for register indirect addressing; since this register pair can also function as data pointer.

The large number of general purpose registers gives more flexibility and ease in the programming. However, the general purpose registers are limited as registers occupy more space on the silicon chip.

Beside these general purpose registers, the 8085 has remaining two 8-bit registers Accumulator (A) and Flag (F) as special purpose registers and two 16 bit registers namely Program counter (PC) and stack pointer (SP).

Accumulator (A)

As discussed in preceding chapters, accumulator is a 8 bit buffer register extensively used in arithmetic, logic, load and store operations as well as in input / output instructions. All the arithmetic and logical operations are performed on the accumulator contents; i.e. one of the operand is always taken into the accumulator.

Flag (F) Register

It is an 8-bit register associated with the execution of instructions in the microprocessor. Out of the 8 bits of flag register, 5 bits contains significant information in terms of status flags. The five flags are:

(i) Sign flag (S)
(ii) Zero flag (Z)
(iii) Carry flag (CY)
(iv) Parity flag (P)
(v) Auxiliary Carry flag (AC)

All the flags except the Auxiliary carry (AC) flag have been discussed in SAP-III computers.

The bit positions reserved for these flags in the flag register (F) is shown in figure 5.2.

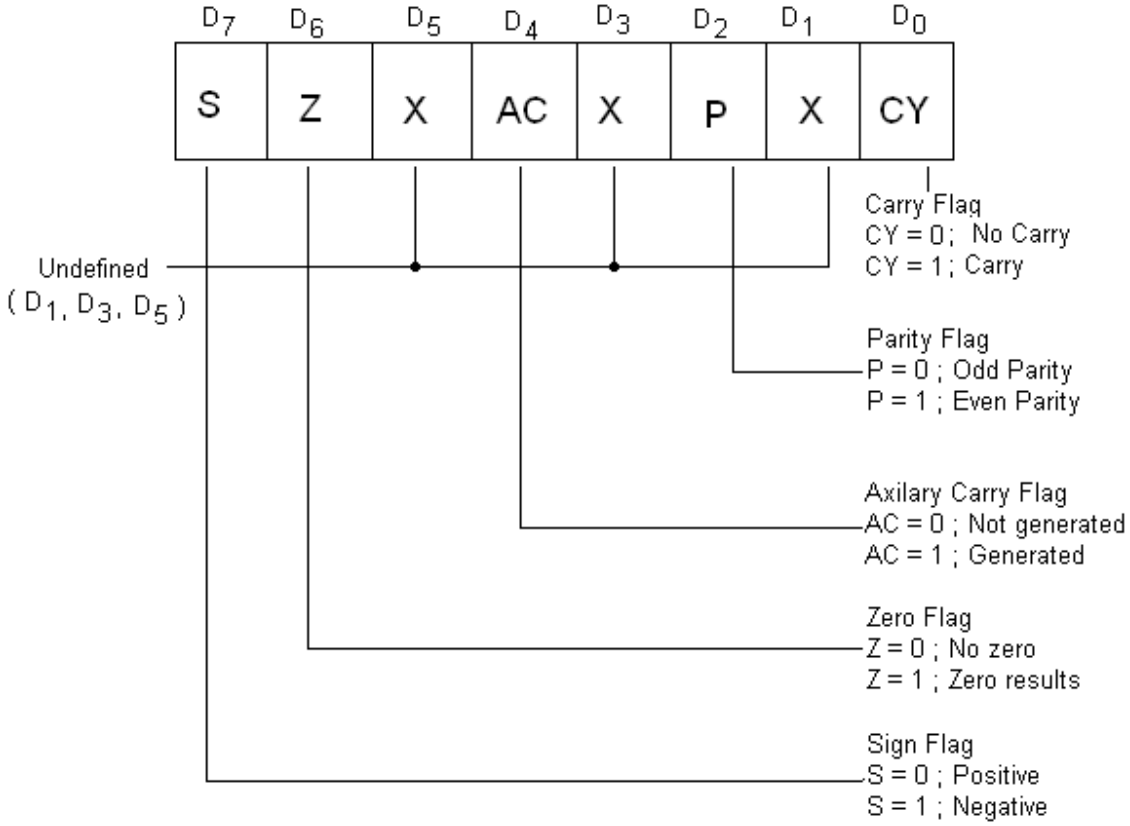

Fig. 5.2

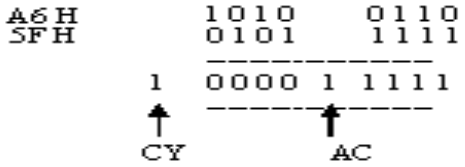
(i) Sign flag (S) The sign flag is set (S = 1), if the result of the operation of the instruction is negative (MSB of the result is 1); otherwise it is reset (S = 0) for the positive result (MSB is zero).

(ii) Zero flag (Z) The zero flag is set (Z = 1) if the result of the operation of the instruction is zero otherwise this flag is reset (Z = 0).
i.e. Z = 1 if the result is zero,
and Z = 0 if the result is not zero.

(iii) Carry flag (CY) The carry flag is set to 1, if there exist a carry (or borrow) to the highest order bit (non-existent 9^{th} position) as a result of the execution of addition or subtraction instructions. If there is no carry (or borrow) to the higher order bit, the carry flag is reset.
i.e. CY = 1 if there is a carry to the highest order bit (or overflow), and CY = 0 if there is no carry to the highest order bit (or no overflow).

(iv) Parity flag (P) After an arithmetic and logic operation, if the result has even number of 1s, then parity bit is set. If on the other hand the result has odd number of 1s, the parity flag is reset.
i.e. P = 1, if the result has even number of 1s,
and P = 0, if the result has odd number of 1s.

(v) Auxiliary carry (AC) This is a new flag in 8085 microprocessor. This flag (AC) is set to 1, if there is an overflow at bit 3 of the accumulator. AC flag is used in BCD arithmetic. This is illustrated as given below:



As shown in figure 5.2, the five bits in flag register are defined. The three bits are undefined. The Accumulator and 8 bits (including three undefined bits) of flag register form a Program Status Word (PSW). The accumulator and flag registers are treated as a 16 bit unit for stack operation.

Program Counter – 16 bit register

The program counter is a 16 bit register. It is used to send 16 bit address to fetch the instruction from the memory. It acts as a pointer which indicates the address of the next instruction to be fetched and executed. The program counter is updated after an instruction has been fetched by the processor. If an instruction is one byte instruction, then the program counter will be updated by one (i.e. PC = PC + 1). Similarly, for two and three byte instructions, the program counter will be updated by two (i.e. PC = PC + 2) or three (i.e. PC = PC + 3) locations respectively.

Stack Pointer – 16 bit register

The stack is an area of RAM (random access memory or read / write memory) in which temporary information is stored. It is stored on First-In-Last-Out (FILO) basis. An address in the RAM area is assigned to the stack pointer where the first information is stored as the first stack entry. This is done by initializing stack pointer by an instruction. Higher stack entries are made at the progressively decreasing addresses.

5.1.2 Address Buffer and Address-Data Buffer

It has already been discussed that 8085 requires 8-bit data bus and 16-bit address bus, as the memory address is of 16 bits. More number of IC pins are required if separate address and data bus are introduced. To restrict the number of pins of 8085 to only 40, lower address lines A_0-A_7 and data lines D_0-D_7 are used in multiplexed mode. The multiplexed lines are designed as Address/Data Bus (AD_0-AD_7). So whenever 16-bit address is transmitted by the microprocessor 8 MSBs of the address lines are sent on the Address Bus (A_{15}-A_8) and 8 LSBs of the lines are sent on the Address/Data Bus (AD_7-AD_0). The 8 LSBs of the address are then latched either into memory or external latch so that the complete address remains available for further operation. The 8-bit Address/Data Bus will now be free for the data transmission.

5.1.3 Arithmetic and Logical Unit (ALU)

The arithmetic and logical unit (ALU) basically consists of accumulator (A), flag register (F) and a temporary register (which is inaccessible by the programmer or user). This unit carries out the arithmetic and logic calculations of the data stored in general purpose registers or in memory locations. The arithmetic operations are ADD, SUB, compare, increments, decrements and complements etc.; while logical operations are AND, OR, XOR and Rotate. The result of these operations could be placed in the accumulator or elsewhere through the internal bus. Arithmetic operations are usually carried out in 2's complement adder / subtrator discussed in the preceding chapter. For these operations, ALU receives the control signals from the timing and control unit.

5.1.4 Timing and Control Unit

This unit consists of the following sections:

1. Instruction Register and Decoder
2. Control signals

1. Instruction Register and Decoder

As discussed in the preceding chapter, the CPU fetches an instruction from the memory for its execution. This instruction can be of 1-3 byte long. The first byte contains the op code of instruction which basically specifies the nature of operation to be performed indicating the length of the instruction. The first byte (op code of the instruction) transferred to 8-bit instruction register through the internal bus of the CPU, becomes available at the instruction decoder. The decoder decodes the op code and directs the control unit to produce the necessary control signals.

2. Control Signals

Following are the control signals of 8085 microprocessor needed for the operation of CPU.

(i) X_1, X_2 and CLK Out

Two pins X_1 and X_2 are provided to be externally connected to a quartz crystal. The clock signal of fixed frequency is generated through the internal circuitry of the processor. The frequency at which the microprocessor 8085 works is half of the crystal frequency. The quartz crystal of 6.144 MHz is used in this processor. This gives the clock frequency of 3.072 MHz (half of the crystal frequency) of 50% duty cycle. The clock period is of about 320 nsec. The output of the clock frequency is also available at CLK out terminal.

(ii) Address Latch Enable (ALE)

The 16 bit address bus is basically divided into two sets. The most significant bits A_7-A_{15} of the address bus are used separately and the least significant bits of the address AD_0-AD_7 are time multiplexed with the bits of bidirectional data bus (D_0-D_7). The AD_0-AD_7 bus serves the dual purpose as they can be used as low-order address bus as well as bidirectional data bus at different times. This is used as address bus, during the first clock cycle of the machine cycle involving memory; and during the remaining clock cycle of the machine cycle, it acts as the data bus. This is accomplished by address latch enable (ALE) signal provided in the processor. During the first clock cycle of the machine cycle ALE is high which enables the lower 8-bit of the address to be latched either into the memory or external latch.

(iii) $\overline{R_D}$ (Read) Signal

This is an active low signal to be connected to memory read input (output enable signal to memories) or to input / output read signal to enable input / output buffer.

(iv) $\overline{W_R}$ (Write) Signal

Similar to read signal ($\overline{R_D}$), write signal ($\overline{W_R}$) is also active low. This signal is used to write to the memory or input / output devices.

(v) *IO/* $\overline{M}$ (Input Output / Memory)

This signal IO/$\overline{M}$ distinguishes that the address and data is meant for either I/O devices or memory. Whenever this signal is high (1), microprocessor will communicate to the I/O devices and whenever it is low (0), microprocessor will communicate to the memory.

(vi) Status Signals (S_0, S_1)

The status signals (S_0, S_1) along with IO/$\overline{M}$ signal indicate the type of machine cycle in progress. The type of machine cycle are op code fetch cycle, memory read cycle, memory write cycle, I/O read cycle or I/O write cycle.

Various types of status codes are given in table 5.2.

Table 5.2

Machine Cycle	IO/$\overline{M}$	S_1	S_0
Op code fetch Cycle	0	1	1
Memory Read Cycle	0	1	0
Memory Write Cycle	0	0	1
I/O Read Cycle	1	1	0
I/O Write Cycle	1	0	1
INTR Acknowledge	1	1	1
Halt	Hi-Z	0	0

(vi) Hold and HLDA

HOLD and HLDA (Hold Acknowledge) signals are used for DMA (Direct Memory Access) operation. In a microprocessor, the data transfer between I/O devices and memory will take place through the microprocessor. The involvement of the processor slows down the data transfer between I/O devices and memory. The transfer of data directly from I/O devices to memory without involvement of microprocessor is called DMA. The DMA will save the time as CPU relinquishes the control of Buses. In this way DMA transfers the large amount of data in a relatively short time. The HOLD and HLDA signals are used in the operation. Whenever HOLD signal is high, CPU temporarily relinquishes its operation by floating the address, data and control buses; and DMA operation is started. A high HLDA (Hold Acknowledge) signal is also sent to DMA controller, indicating that CPU has received the hold request. Whenever the data transfer is complete, then the control to CPU is returned back by sending a HOLD signal. Further the HLDA signal goes low.

(viii) READY signal (Input)

Some peripheral devices connected to 8085 microprocessor operate at much slower speed than the processor. To synchronize the speed of CPU and peripheral devices or to slow down the speed of 8085, the READY signal is used. If the READY signal is high the peripheral device is ready and the processor can complete the data transfer. If

this signal is low the microprocessor waits (by generating a number of NOP T-states) till it goes high.

(ix) $\overline{\text{RESET IN}}$ and RESET OUT

The signal $\overline{\text{RESET IN}}$ may be low from the operator Reset button or from the processor. When the signal is low, the CPU will reset the program counter, instruction register and other circuits. It also sends a high **RESET OUT**. The **RESET OUT** signal goes to peripheral devices to reset or initialized. When $\overline{\text{RESET IN}}$ signal goes high and **RESET OUT** goes low, the data processing may begin.

5.1.5 Interrupt Control

Sometimes it is necessary to interrupt the execution of the main program. For this an interrupt request is obtained from the I/O devices. After receiving the interrupt request (*INTR*), processor temporarily stops what it was doing and attends to the I/O device. $\overline{INTA}$ is an interrupt acknowledge signal which is sent by the microprocessor after INTR signal is received. After the work of the I/O device is complete it returns to what it was doing earlier.

Basically 8085A has five hardware interrupts namely:

INTR
RST 5.5
RST 6.5
RST 7.5
and **TRAP**

If two or more of these interrupts are active at the same time, the 8085 takes them in order of priority level. The priority levels of these interrupts are given in table 5.3.

Table 5.3

Interrupts	Priority
TRAP	**1**
RST 7.5	**2**
RST 6.5	**3**
RST 5.5	**4**
INTR	**5**

The details of these instructions will be discussed in chapter 7.

5.1.6 Serial I/O Control

Serial input / output control circuit incorporated in this microprocessor is used for the data transmission. For this purpose two pins SID and SOD are provided in the serial input/output control unit. The SID (Serial Input Data) terminal receives the serial data stream from an input device, the control unit converts serial data stream to parallel data before it is used by the computer. After the conversion 8-bit parallel data is stored in the accumulator. Similarly, SOD (Serial Out Data) terminal outputs the 8-bit parallel available with the accumulator into serial form to the peripheral device connected with the computer.

5.2 PIN DESCRIPTION OF 8085

The pin details and logical schematics of the 40 pin dual line package (DIP) IC 8085 are shown in figures 5.3(a) and (b) respectively. Fig. 5.3 (c) shows the shape of the microprocessor. The descriptions of various pins of the microprocessor are given below:

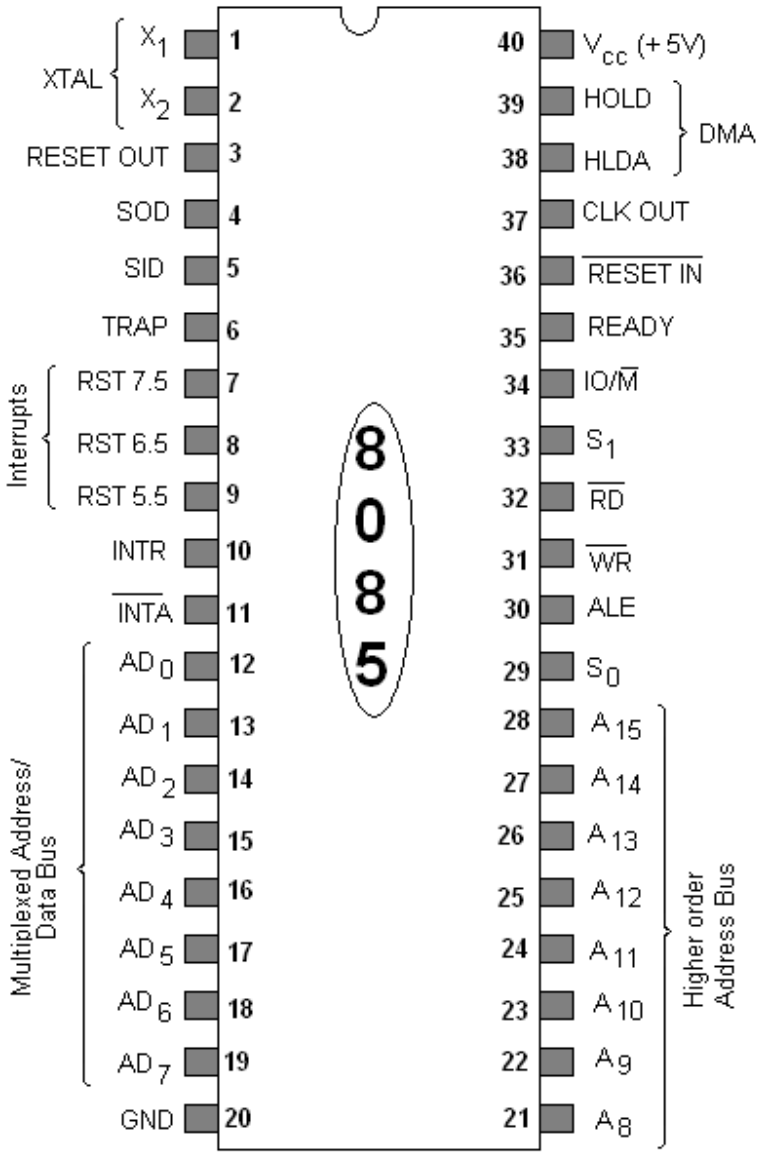


Fig. 5.3 (a)

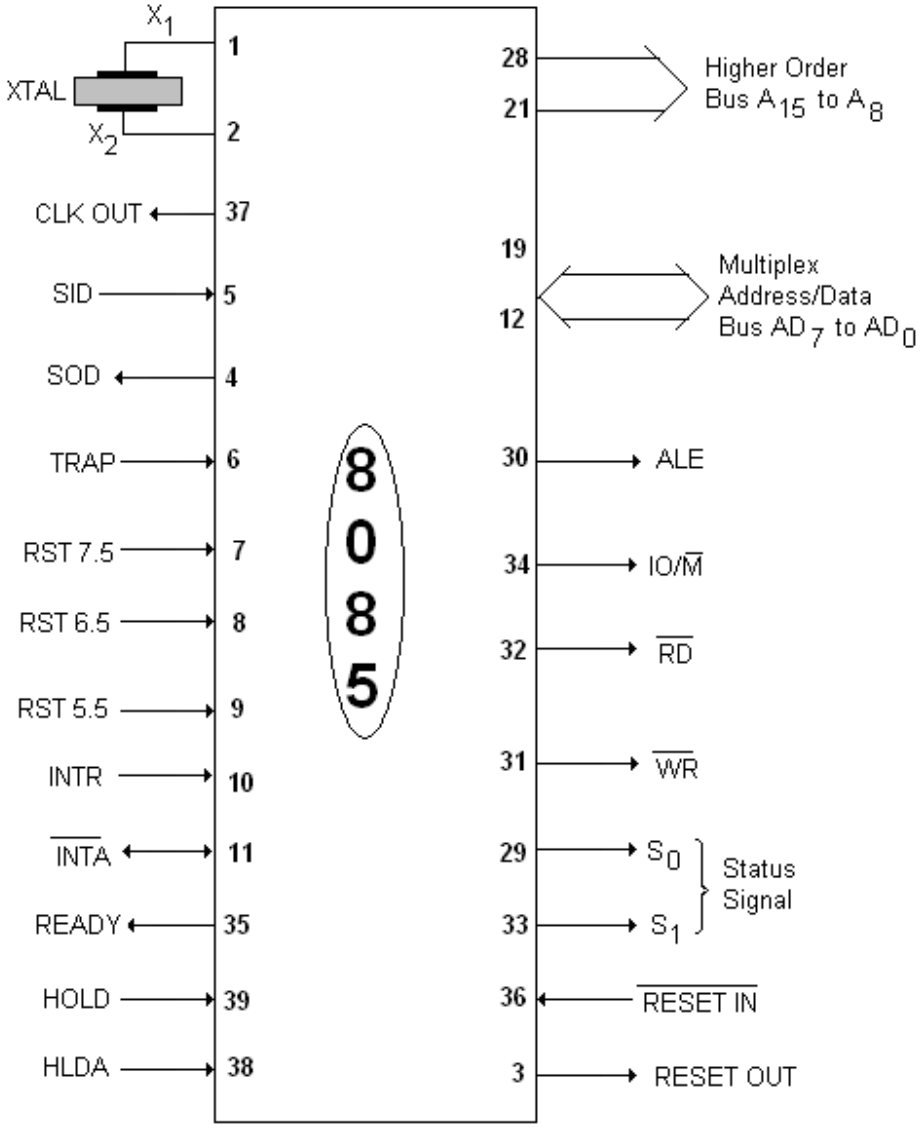

Fig. 5.3 (b)

Fig. 5.3 (c)

PIN NOS. 1 and 2:

These X_1 and X_2 pins are to be connected to an external quartz crystal, L-C or R-C network which drives the internal clock generator. The clock signal of appropriate frequency is determined when a quartz crystal is connected to the on-chip oscillator as shown in figure 5.4(a). The oscillator output from the Schmitt trigger drives a flip-flop which divides the frequency by a factor of two. The circuit produces two clock signals Φ1 (CLK) and Φ2 ($\overline{CLK}$) to derive the internal circuit of the microprocessor. A 6.25 MHz crystal is used to provide 3.125 MHz internal clock frequency.

Generally, quartz crystal is used for the On-chip oscillator for the accurate and stable clock frequency, though a parallel resonant L-C circuit may be used for the frequency determining network as shown in figure 5.4(b). The network produces a signal whose frequency tolerance is about $\pm 10\%$. The component values may be chosen from the following formula:

$$f = \frac{1}{2\pi\sqrt{L(C + C_{in})}}$$

The input capacitance Cin is approximately 15 Pf. To minimize the variations in frequency, it is recommended to choose C as 30 Pf.

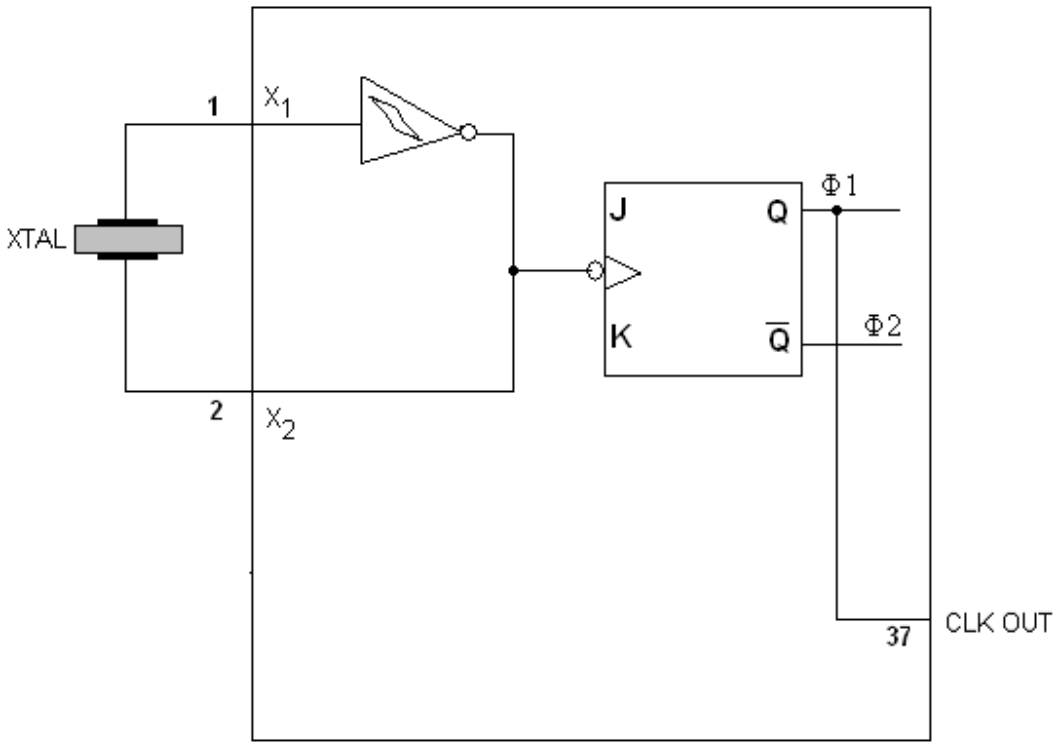

Fig. 5.4(a)

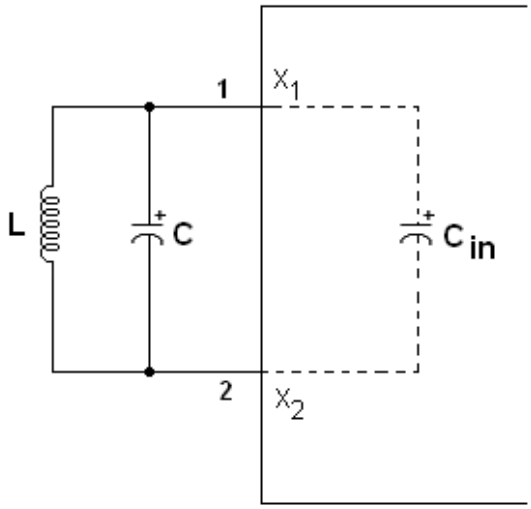

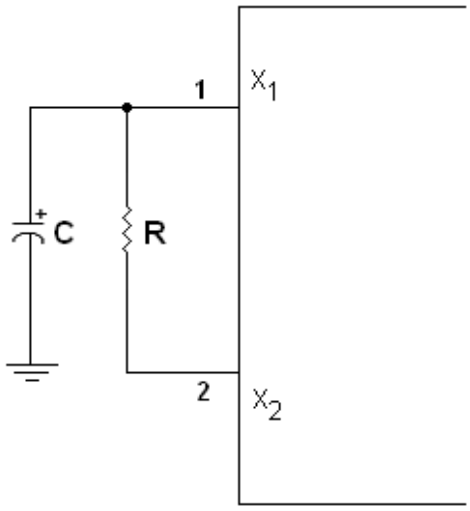

Fig. 5.4 (b) **Fig. 5.4 (c)**

An R-C network may also be used as the frequency determining network for the on-chip oscillator of the microprocessor as shown in figure 5.4(c). The driving frequency generated by this circuit is approximately 3MHz. It is not recommended to use the frequencies higher or lower than this.

PIN NO. 3

This is **RESET OUT** signal, which indicates that CPU is being reset. When it is high, system is reset. The signal is synchronized to the processor clock and lasts for an integral number for clock periods. When the **RESET OUT** signal goes low, the processing begins.

PIN NOS. 4 and 5

Pin Nos. 4 and 5 indicate SOD (Serial Out Data) and SID (Serial In Data) terminals respectively. These pins are associated with Serial Input/Output control unit for 8085 microprocessor. As already discussed these pins are used for the serial data transmission. The SOD output pin can deliver a serial data stream to a peripheral device. On executing SIM (Set Interrupt Mask) instruction, if bit D_6 is set to 1, the content of D_7 bit (set or reset) of the accumulator is latched on the SOD pin as shown in figure 5.5(a).

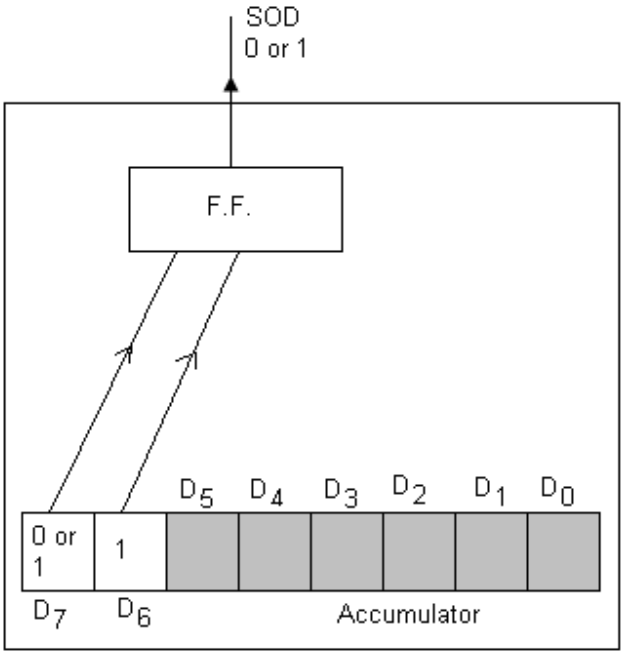

Fig. 5.5 (a)

The data on the SID line (PIN 5) loads into accumulator at bit D_7 whenever a RIM instruction is executed as shown in figure 5.5(b).

The details of SIM and RIM instructions will be discussed in chapter 7.

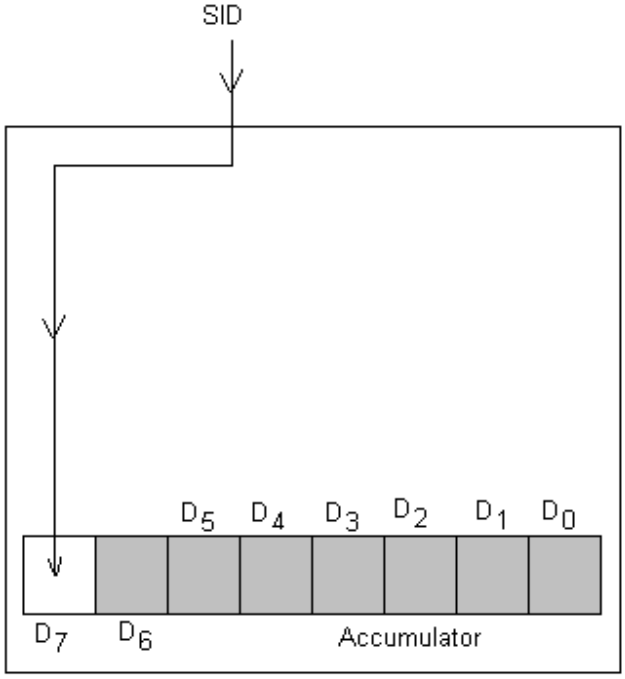

Fig. 5.5 (b)

PIN NOS. 6 to 11

The interrupt control unit of the microprocessor contains these pins. The Pins 6 to 11 are restart interrupts named as:

TRAP (Pin No.6)	I Priority
RST 7.5 (Pin No. 7)	II Priority
RST 6.5 (Pin No. 8)	III Priority
RST 5.5 (Pin No. 9)	IV Priority
INTR (Pin No. 10)	V Priority

The TRAP has the highest priority and INTR has the lowest priority. The priority level is of importance if two or more interrupts become active at the same time. The TRAP is non-maskable interrupt. It is both edge and level sensitive.

The interrupts (TRAP, RST 7.5, RST 6.5 and RST 5.5) are also called vector interrupts, as each interrupt has fixed memory location (vector location) for the transfer of control from the normal execution of the routine. The vector locations of these interrupts are given in table 5.4. As soon as any of these pins 6 to 10 are active (high), the internal circuit of 8085 stops the normal execution of program and the program control is transferred to the corresponding memory location (vector location).

Table 5.4

Interrupts	Memory locations
TRAP	**0024 H**
RST 7.5	**003C H**
RST 6.5	**0034 H**
RST 5.5	**002C H**

INTR (Pin No. 10) is a general purpose interrupt and has the lowest priority. As soon as Pin No. 10 is high, the microprocessor stops the execution of normal program and after completing the instruction at hand, it goes to CALL instruction. The INTR is enabled or disabled by the instructions ET (Enable Interrupts) or DI (Disable Interrupts) respectively.

The Pin No. 11 is an Interrupt Acknowledge ($\overline{\text{INTA}}$) signal. A low (logic 0) to this pin indicate that the microprocessor has acknowledged the request from the peripheral device. It is also used to activate the interrupt controller.

PIN NOS. 12 to 19

Pin Nos. 12 to 19 (AD_0-AD_7) form bi-directional multiplexed Address/Data Bus. The least significant 8 bits of the memory address (or I/O Address) appear on the bus during the first T-states of a machine cycle. It then becomes the data bus during the next T-states.

PIN NO. 20

Pin No. 20 is the ground terminal.

PIN NOS. 21 to 28

The Pin Nos. 21 to 28 (A8-A15) form unidirectional most significant 8 bits of memory address or 8 bits of the I/O address. It remains in the high impedance state during HOLD, HALT and RESET modes.

PIN NOS. 29 to 33

The Pin Nos. 29 to 33 labled as S_0 and S_1 respectively are known as status signals. These status signals along with $IO/\overline{M}$ signal indicate the various operations as indicated in table 5.5.

Table 5.5

Machine cycle	**$IO/\overline{M}$**	**Status**		**Control signals**
		S_1	**S_0**	
Op code Fetch	**0**	**1**	**1**	$\overline{RD} = 0$
Memory Read	**0**	**1**	**0**	$\overline{RD} = 0$
Memory Write	**0**	**0**	**1**	$\overline{WR} = 0$
I/O Read	**1**	**1**	**0**	$\overline{RD} = 0$
I/O Write	**1**	**0**	**1**	$\overline{WR} = 0$

PIN NO. 30

The Pin No. 30 is known as ALE (Address Latch Enable) terminal. When this signal is high the information carried on the multiplexed address/data bus (AD_0-AD_7) is the lower 8 bits of the address. It also enables the low order address (AD_0-AD_7) from the multiplexed address/data bus to latch either into the memory or the external latch. The ALE signal separates the low order address and data from the multiplexed Address/data Bus. This is illustrated in figure 5.6.

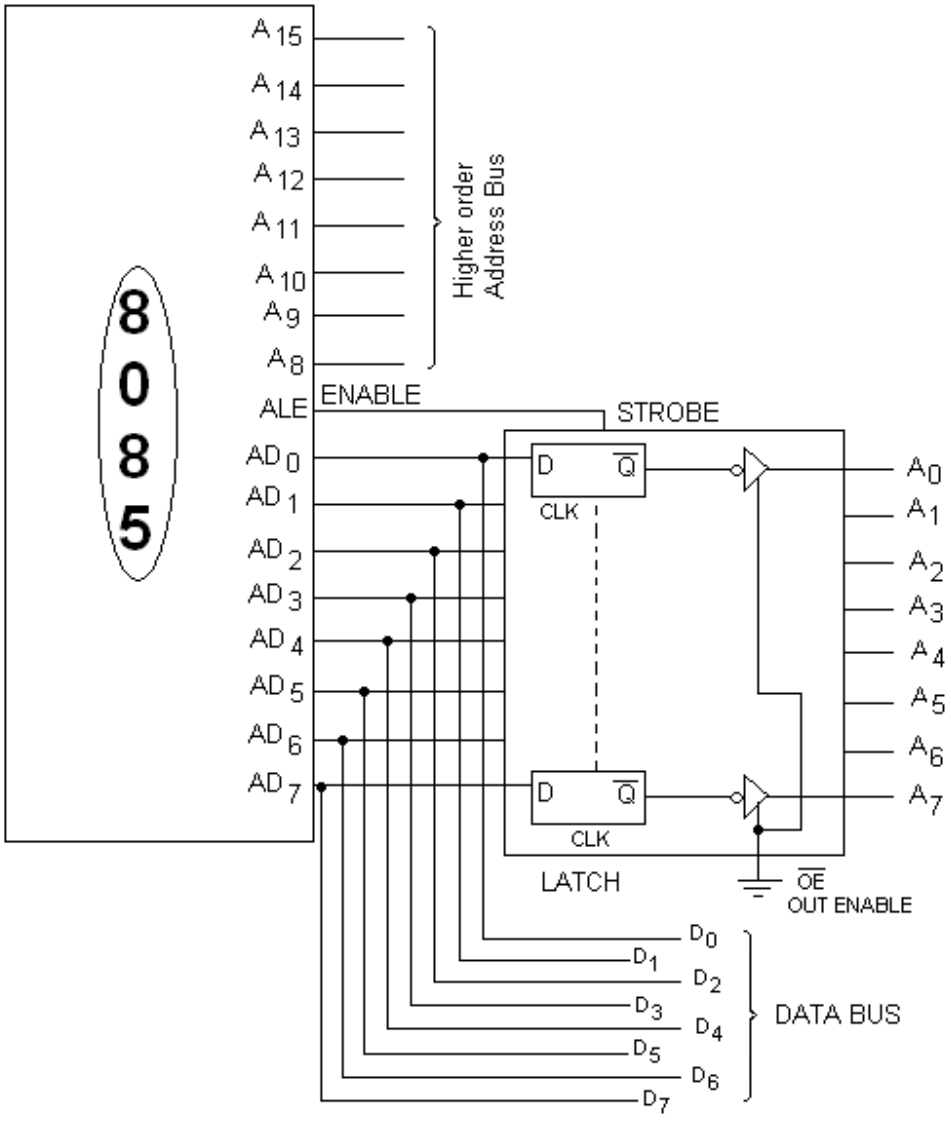

Fig. 5.6

PIN NOS. 31, 32 and 34

The Pin Nos. 31 and 32 are the two control signals $\overline{WR}$ (Write bar) and $\overline{RD}$ (Read bar) respectively. The pin 34 carries $IO/\overline{M}$ signal which is one of the status signals. The other status signals are S0 and S1 discussed earlier. A low $\overline{WR}$ signal generated by the microprocessor sends (writes) data into I/O devices or memory. Similarly, a low $\overline{RD}$ signal generated by the microprocessor reads (receives) the data from the I/O devices or memory locations. The $IO/\overline{M}$ signal indicates whether the address on the address bus is meant for I/O devices. However, a low to this signal indicates that the address on the address bus is meant for memory location. The $\overline{RD}$, $\overline{WR}$ and $IO/\overline{M}$ signals function together.

PIN NO. 35

The Pin No. 35 is known as READ signal which forces the microprocessor to wait till the data become available from the memory or input/output devices. This signal is needed to synchronize the speed of the microprocessor with I/O devices or memory as the memory or I/O devices are not as fast as the microprocessor. When the READ signal is low, the microprocessor waits till the READY signal is 1. As soon as READY signal is 1, the microprocessor knows that the data are available from the memory or I/O devices.

PIN NO. 36

This pin is $\overline{\text{RESET IN}}$ signal. This input carrying signal may be operated by the operator using the RESET button provided externally or it may be operated directly from the other source. When this signal is low (momentarily), the CPU will reset the program counter, instruction register, all interrupts (except TRAP) are disabled, SOD signal becomes low and Data, address and control buses are floated. When this signal goes high, the data processing begins.

PIN NO. 37

This pin carries CLK OUT signal. It is derived from the on-chip oscillator, which goes to peripherals to synchronize their timings.

PIN NOS. 38-39

The Pin Nos. 38 and 39 are the HOLD and HLDA (Hold Acknowledge) signals respectively. These signals are used in DMA (Direct Memory Access) operations. As shown in figure 5.7, when any I/O device indicates that the data are ready for DMA transfer, a high HOLD signal is sent by the DMA controller to the 8085 microprocessor. It is in fact a request signal from the DMA controller to the microprocessor. The microprocessor then sends a high signal to DMA controller indicating that the microprocessor has received the request from the I/O devices and will relinquish the address, data and control bus after completing the current instruction. The DMA controller thus carries out the data transfer. A low HOLD signal will return the control to the microprocessor.

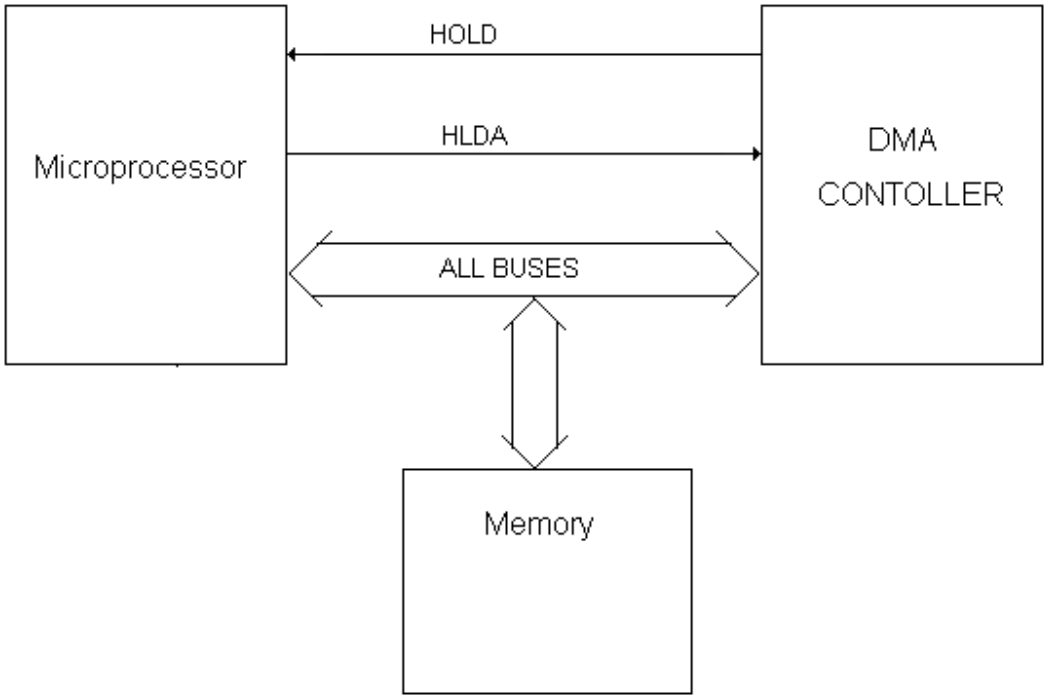

Fig. 5.7

PIN NO. 40

The pin 40 is +VCC, which is to be externally connected to +5 volt d.c. supply.

5.3 INSTRUCTION SET OF 8085 MICROPROCESSOR

The 8085 includes all the instructions of SAP-III. In addition there are few more instructions which will be discussed below. These new instructions were not considered in SAP-3 because of its architecture.

LHLD address **(Loads the H-L pair direct)**

This instruction loads the H-L pair direct with two bytes already stored in two consecutive memory locations starting at the specified memory address. The contents stored in the memory location whose address is given with the instruction will be loaded to the L-register; and the contents stored in the next memory location (address + 1) will be loaded to the H-register.

i.e. $[L] \leftarrow [M_{address}]$

and $[H] \leftarrow [M_{address+1}]$

For example, let 2A H is stored in the memory location 2100 H and 2B H is stored in the memory location 2101 H, then after the execution of the instruction LHLD 2100 H , the L-register will have 2A H and H-register will have 2B H.

None of the flags is affected with this instruction.

SHLD address **(Stores the H-L pair direct)**

This instruction does the reverse operation of LHLD. The instruction *SHLD address* stores the contents of L-register to memory location whose address is given with the instruction; and the contents of H-register are stored in the next consecutive memory location (address + 1).

i.e. $[M_{address}] \leftarrow [L]$

and $[M_{address+1}] \leftarrow [H]$

No flag is affected with this instruction too.

For example, if $[L] = 3A$ H and $[H] = 3B$ H, then after the execution of the instruction SHLD 2200 H will result.

$[M_{2200H}] \leftarrow 3A$

and $[M_{2201H}] \leftarrow 3B$

LDAX rp **(Loads the Accumulator Indirect)**

This instruction loads the accumulator, the contents already stored in the memory location addressed by the register pair (rp). Here rp represents B-C or D-E register pair. The H-L register pair is not included in this instruction.

i.e. $[A] \leftarrow [M_{rp}]$

The possible combinations of the instruction are:

LDAX B

LDAX D

No flag is affected with the execution of this instruction.

For example, if [D] = 25 H, [E] = 00 H

and $M_{2500\ H}$ = 34 H,

then after the execution of the instruction LDAX D, the accumulator will have:

$[A] \leftarrow [M_{2500H}]$

i.e. A = 34 H

It is worth while to mention that the instruction LDAX H does not exist, because the contents stored in the memory location addressed by H-L register pair may be loaded to accumulator by the instruction *MOV A, M*.

STAX rp **(Stores the Accumulator Indirect)**

The *STAX rp* instruction does the reverse operation of *LDAX rp*. This instruction stores the accumulator contents in the memory location addressed by the register pair (rp). Here too rp represents B-C or D-E register pair. The H-L register pair is not included in this instruction.

i.e. $[M_{rp}] \leftarrow [A]$

The possible combination of this instruction are:

STAX B

STAX D

No flag is affected with the execution of this instruction.

For example, if B = 21 H, C = 00 H

and A = 3A H,

then after the execution of the instruction STAX B, 3A H will be stored in the memory location 2100 H.

i.e. $[M_{2100H}] = 3AH$

The combination *STAX H* is not included in this instruction as *MOV A, M* performs the same operation.

XCHG **(Exchange the contents of H-L register with D-E register)**

This is one byte instruction and no operand is needed with it. It exchanges the contents of H and L register with D and E registers respectively.

i.e. $[\text{H}] \leftrightarrow [\text{D}]$ and $[L] \leftrightarrow [E]$

For example:

If H = 25 H , L = 32 H

and D = 12 H, E = 1B H

then after the execution of *XCHG* instruction, we have:

H = 12 H, L = 1B H

and D = 25 H, E = 32 H

The instruction *XCHG* is generally used to keep track of more than one memory location at a time without using LDAX and STAX instructions.

Let us write a program to add two numbers stored in memory locations 2100 H and 2201 H without using *LDAX* and *STAX* instructions. The answer is to be loaded in the memory location 2100 H.

```
LXI H, 2201 H  ; Loads H = 22 H and L = 01 H
LXI D, 2100 H  ; Loads D = 21 H and E = 00 H
MOV A, M       ; [A] ← [M2201H]
XCHG           ; H = 21 H, L = 00 H and D = 22 H, E = 01 H
ADD M          ; [A] ← [A] + [M2100H]
MOV M, A       ; [M2100H] ← [A]
HLT
```

In this program no LDAX and STAX instructions are used.

DAA **(Decimal Adjust the Accumulator)**

The *DAA* is one byte instruction and no operand is needed with this instruction. It adjusts the accumulator to packed BCD (Binary Coded Decimal) after addition of two BCDs. In other words, after addition of two hexadecimal numbers if this instruction is used then the result in decimal form is obtained. For this Auxiliary Carry Flag (AC) and Carry Flag (CY) take care of this instruction.

It functions in two steps:

1. If the lower nibble (lower 4-bits) of the accumulator is greater than 9 or Auxiliary carry flag is set, then it adds 06 H to the accumulator.
2. Subsequently, if the higher nibble (higher 4-bits) of the accumulator is now greater than 9 or the carry flag (CY) is set, it adds 60 H to the accumulator.

All the flags are affected with this instruction.

Example 5.1 *What will be the value of accumulator, CY and AC flags after the execution of the following program:*

```
MVI A, 38 H
ADI 87 H
DAA
HLT
```

Solution.

```
A = 38 H      0 0 1 1  1 0 0 0
Adds 87 H     1 0 0 0  0 1 1 1
              ---------------------
```

```
  1 0 1 1  1 1 1 1
  0 0 0 0  0 1 1 0      Lower nibble is more than 9
-----------------------
  1 1 0 0  0 1 0 1      AC = 1
  0 1 1 0  0 0 0 0      Upper nibble is more than 9
-----------------------
1 0 0 1 0  0 1 0 1
                        Result = 125 (Decimal)
```

A = 0 0 1 0 0 1 0 1 CY = 1 AC = 1

PCHL **(Copies H-L to PC)**

This is one byte instruction and no operand is needed with this instruction. It copies the contents of H-register to high-order byte of the program counter (PC) and the contents of L-register to low order byte of the program counter.

$[PC] \leftarrow [HL]$ i.e. $[PCH] \leftarrow [H]$ and $[PCL] \leftarrow [L]$

For example if PC = 2106 H and HL = 2500 H

then after the execution of the instruction *PCHL* will result:

PC = 2500 H

No flag is affected with the instruction.

This instruction is basically an unconditional jump instruction as is evident from the above example.

SPHL **(Copies HL to Stack Pointer SP)**

This is also one byte instruction as no operand is used. The *SPHL* instruction copies the contents of H-register to high order byte stack pointer (SP) and the contents of L-register to low order byte of stack pointer (SP).

$[SP] \leftarrow [HL]$ i.e. $[SPH] \leftarrow [H]$ and $[SPL] \leftarrow [L]$

None of the flags is affected with this instruction.

For example if H = 23 H and L = 45 H

and SP = 2501 H

then after the execution of the instruction *SPHL* will result:

SP = 2501 H

This is another way of initialization the stack pointer.

XTHL ***(*****Exchanges the top of the stack with H-L register pair)**

The *XTHL* is one byte instruction and does not require any operand. The top byte of the stack is exchanged with L-register and next byte of the stack is exchanged with H-register.

i.e. $[L] \leftrightarrow [M_{SP}]$

and $[H] \leftrightarrow [M_{SP+1}]$

For example if H = 21 H L = 02 H

and M_{SP} =1A H M_{SP+1} = 2C H

as shown in figure 5.8(a), then after the execution of the instruction *XTHL* will result:

H = 2C H L = 1A H

and M_{SP} = 02 H M_{SP+1} = 21 H

as shown in figure 5. 8(b).

No flag is affected with the instruction.

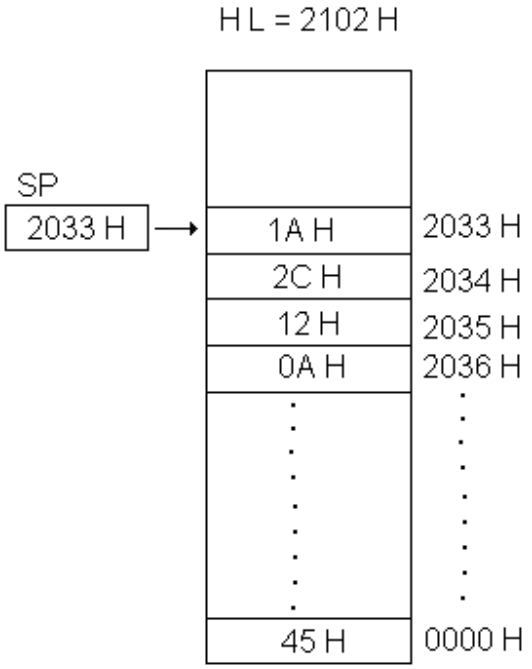

Fig. 5.8 (a)

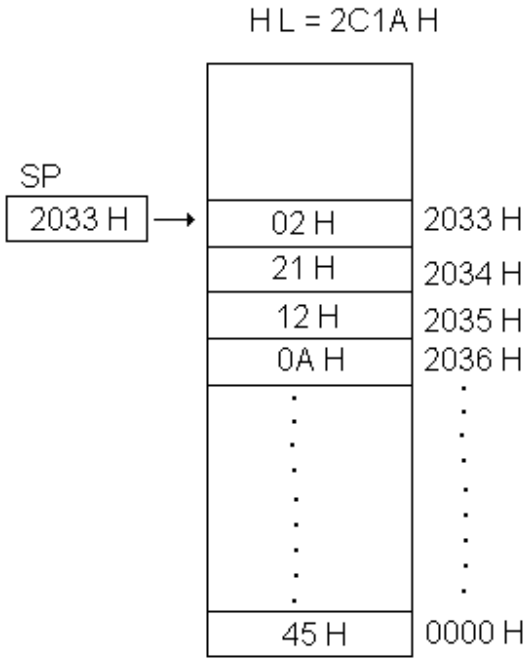

Fig. 5.8 (b)

5.4 TIMING DIAGRAM FOR 8085 INSTRUCTIONS

The working of 8085 microprocessor can best be understood by considering the timing diagrams of its few instructions. The graphical representation depicting the necessary steps carried out in a machine cycle is known as Timing Diagram. As is well known that the total time required for the execution of an instruction is the time required to fetch and execute an instruction.

i.e. **Instruction Cycle = Instruction fetch + Instruction execution**

The instruction cycle may be of one, two or three bytes. During the fetch cycle, an instruction of the program (op code) is extracted from the memory locations and copied in the instruction register (IR) of C.P.U.

The op code of the instruction copied in the instruction register (IR) is decoded during the execution cycle to perform the specific activities.

It may further be mentioned that an instruction cycle may take one to five machine cycles. Generally, first machine cycle known as op code fetch cycle, has either four or six T-states and the remaining machine cycles called execution cycles, have two or three T-states. A T-state represents one clock cycle.

The NOP is the shortest instruction which takes only one machine cycle with four T-states. However, the CALL is the longest instruction which takes five machine cycles with 18 T-states.

Here the timing diagrams of a few instructions will be discussed.

5.4.1 Timing Diagram of *MOV reg, M*

The timing diagram of the instruction

MOV reg, M

is shown in figure 5.9.

This is an indirect read instruction and takes two memory cycles (M_1 and M_2). The first machine cycle (M_1) is known as instruction fetch cycle, during which the op code of the instruction is fetched from the memory. This machine cycle takes four T-states. The second machine cycle M_2 is known as the execution cycle during which the data from the memory location addressed by H-L register pair is transferred to the given register. The second machine takes three states.

During the first T-state (T_1) of M_1 cycle, microprocessor sends the address of the memory location where the op code of the instruction ***MOV reg, M*** is stored, to the address lines. The high order byte of the PC (PCH) is placed on A_8-A_{15} lines and it stays on till T_4. The low order byte of PC (PCL) is placed on the address data lines (AD_0-AD_7) which stays on only during T_1-state. For this purpose ALE (Address Latch Enable) signal gives a positive pulse midway through first T-state (T_1), which latches the low order byte of the address into the memory chips. The $IO/\overline{M}$ signal goes low at the beginning of T_1 state; this enables the peripheral chips for a memory operation rather than input/output operation. It is customary to represent the address lines by double sided waveforms as the address bits may be high or low (ref. fig. 5.9).

MOV reg, M

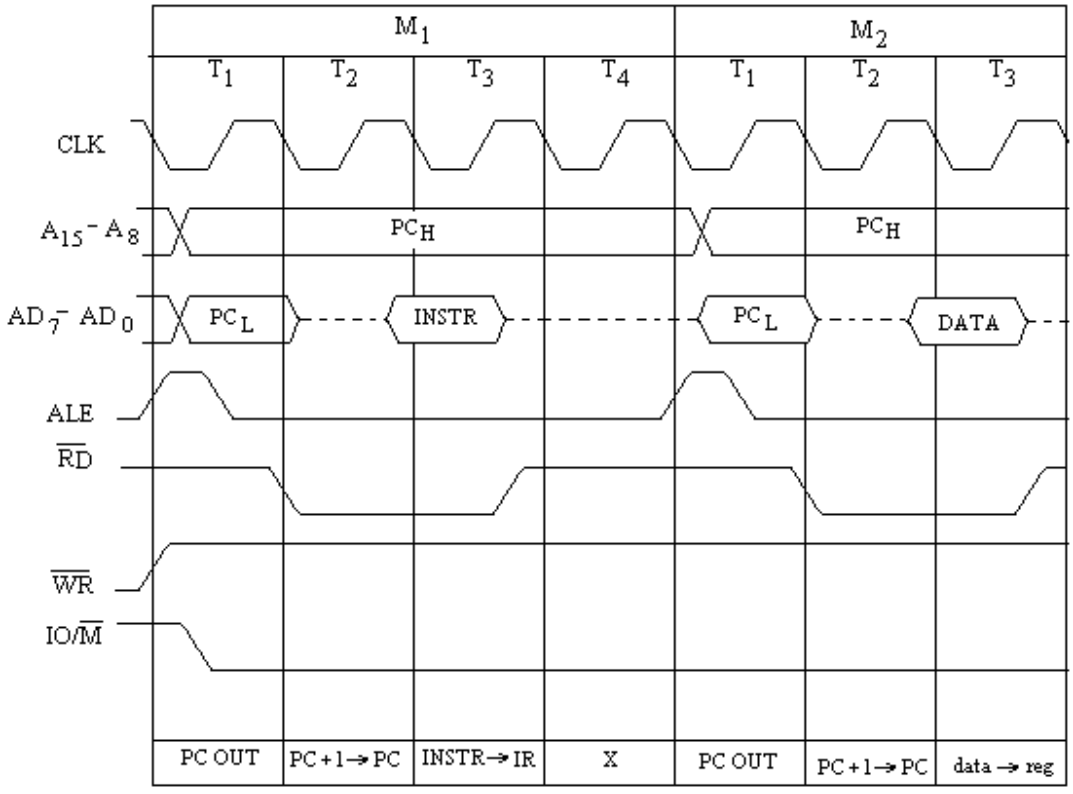

Fig. 5.9

During the second T-state (T_2) of this op code fetch cycle, program counter (PC) is incremented (PC = PC + 1). The address disappears from the address data bus (AD_7-AD_0) at the beginning of T_2 state. This is shown by dashed line indicating the data on the

bus is invalid or meaningless. At the beginning of T_2 state $\overline{RD}$ signal goes low and remains low till the middle of the T_3 state.

During the third T-state (T_3) of M_1 machine cycle, the op code of the instruction is read out from the memory which is sent to the instruction register (IR) i.e. $INSTR \rightarrow IR$.

The fourth T-state (T_4) of M_1 machine cycle is denoted by **X** which indicates that this T-state is needed for the instruction decoding and other internal operations before the execution cycle.

Now the second machine cycle M_2 known as execution cycle starts. During the first T-state of this execution cycle the contents of H-L register pair are placed on the address bus and address data bus. Basically, it performs the same operation as the T_1-state of M_1 cycle. During T_2 and T_3 states of M_2 machine cycle the data is read from the memory and copied in the specified register.

This completes the instruction ***MOV reg, M***. It may be noted that this instruction needs two machine cycles with 7 T-states.

5.4.2 Timing Diagram of *MOV M, reg*

This is an indirect write instruction. The timing diagram of MOV M, reg instruction is shown in figure 5.10. The first three states of memory fetch cycle M_1 are the same as for ***MOV reg, M***. During fourth T-state (T_4) of M_1, the contents of specified register are copied in the temporary register.

During the T_1-state of second machine cycle M_2, the contents of H-L pair are placed on the address and address data bus. As usual during this state ALE sends a high pulse. During T_2 and T_3 states of machine cycle M_2, contents of temporary register are transferred (copied) to the specified address. Since it is memory write instruction, so at the beginning of T_2-state $\overline{WR}$ signal activates (becomes low) and it remains low till half way through its T_3-state.

This instruction also takes two machine cycles with 7 T-states.

MOV M, reg

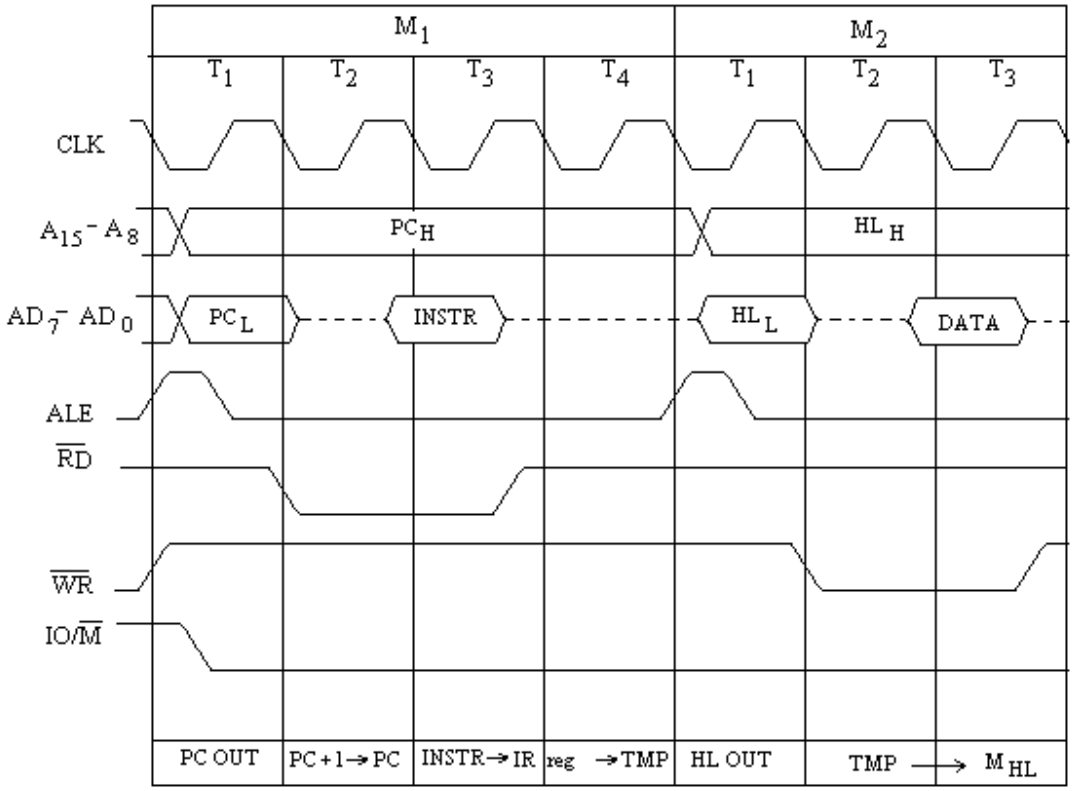

Fig. 5.10

5.4.3 Timing Diagram of *MVI reg, data*

Figure 5.11 illustrates the timing diagram of the instruction ***MVI reg, data***. This is an immediate move instruction. It is two byte instruction; one byte is used for the op code of the instruction and the other byte is used for the data. During T_1, T_2 states of op code fetch cycle M_1 the op code of the instruction (INSTR) is loaded in the instruction register (IR). The operation for these T-states is similar to other instructions discussed earlier. The T_4-state of this cycle M_1 is for decoding.

In the second machine cycle M_2, the contents of the program counter (PC) is placed on the address and address data buses during its T_1 state. This is the address of the second byte. During T_2 of M_2 cycle, the PC is incremented. At the same time memory is accessed and immediate read data is loaded to the specified register during T_3-state of M_2 machine cycle. This instruction takes two machine cycles with 7 T-states.

MVI reg, data

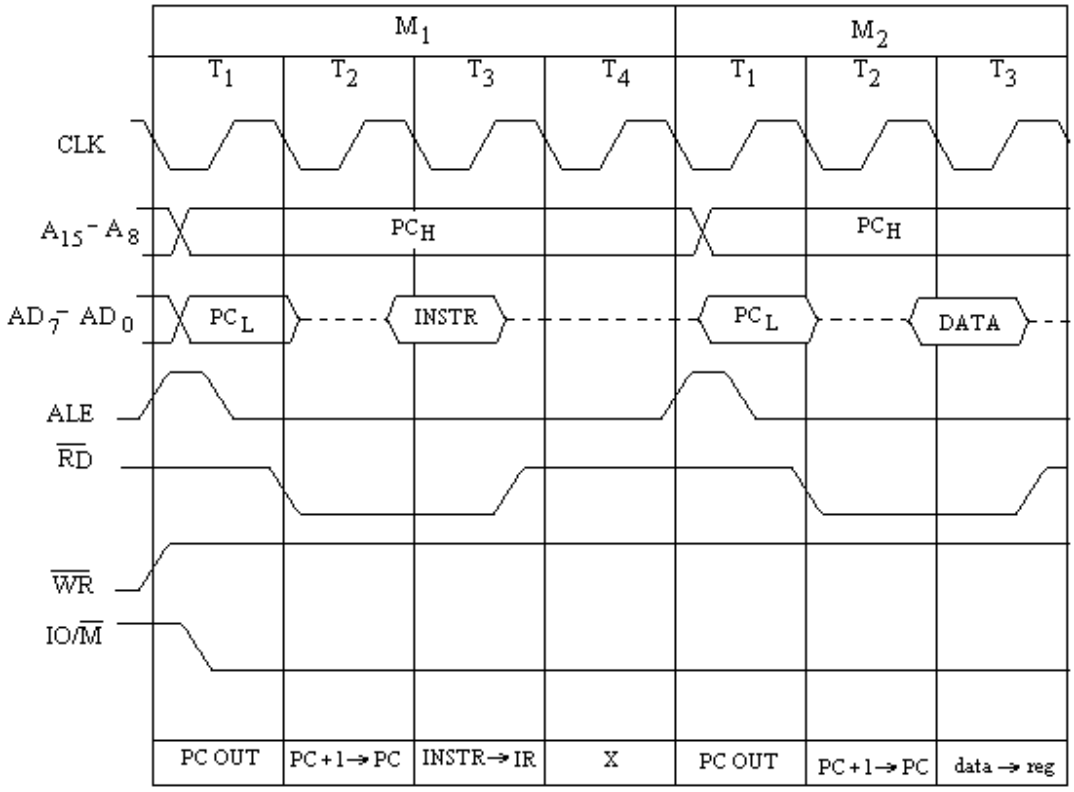

Fig. 5.11

5.4.4 Timing Diagram of *MOV reg2, reg1*

The timing diagram of ***MOV reg2, reg1*** is shown in figure 5.12. This instruction copies the contents of reg2 to reg1. So T_1, T_2 and T_3 states of the op code fetch cycle M_1 as usual indicate PC OUT, increment state ($PC+1 \rightarrow PC$), copying of the op code on the instruction to the instruction register ($INSTR \rightarrow IR$) operations respectively. Accordingly, ALE sends a high pulse at the beginning of T_1-state, $\overline{RD}$ activates (low) at the beginning of T_2 state till the middle of T_3 state till the middle of T_3 state of M_1 cycle. The $IO/\overline{M}$ signal becomes low at the beginning of T_1 till the end of T_3 of M_2 machine cycle. During T_4 state the contents of reg2 is copied in Temporary register ($reg2 \rightarrow TMP$).

This instruction does not need address bus and address data bus during the second machine cycle M_2. The only thing to happen during M_2 cycle is the transfer of the contents of Temporary register to reg1, for which address and address data buses are not required. So time process starts i.e. during the second machine cycle M_2 of the instruction ***MOV reg2, reg1,*** fetching operation of the next instruction will take place. This is called Fetch Execute Overlap (FEO). Because of FEO, the new address of PC is placed on the address and address data buses during T_1 state of M_2 machine cycle. Thus at the trailing

edge of ALE signal, this address is latched into the memory chips. The contents of temporary register are copied into reg1 at the T2 state of this machine cycle. This completes the execution ***MOV reg2, reg1*** instruction. However at the same T-state, program counter is incremented. The op code of the next instruction is copied in IR during T_3-state of M_2.

It may be mentioned here that as shown in figure 5.12, this instruction takes two machine cycles with 7 T-states; but because of FEO only one machine cycle with 4 T-states are counted to fetch and execute this instruction.

MOV reg2, reg1

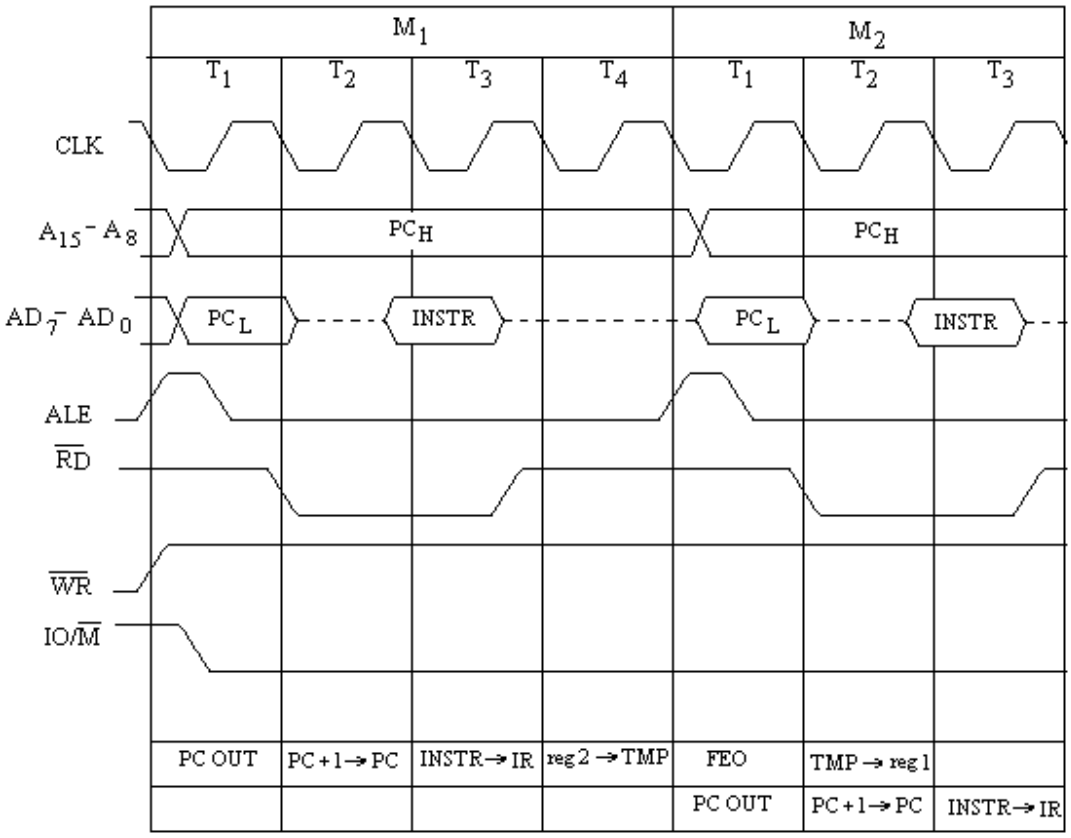

Fig. 5.12

5.4.5 Timing Diagram of *MVI M, data*

The timing diagram of ***MVI M, data*** instruction is shown in figure 5.13. This is a two byte instruction which takes 3 machine cycles with 10 T-states. The machine cycle M_1 is the op code fetch cycle, whose operation has already been discussed. In the T_1 state of M_2 cycle, the incremented address of PC is latched into memory chips. The T_2-state is the increment state and during the T_3 state of M_2 data is transferred to temporary register. This machine cycle is memory read cycle.

The third machine cycle is basically memory write cycle during which the contents of temporary register are copied in the memory location addressed by H-L register pair. In the T_1 state of the machine cycle M_3, the contents of H-l register pair is placed on the address bus and address data bus. It is then latched in the memory chips. In T_2 state the $\overline{WR}$ signal is low till the middle of T_3 state of this cycle. So the contents of

temporary register are copied in M_{H-L} location during T_2 and T_3 state of M_3 machine cycle.

MVI M, data

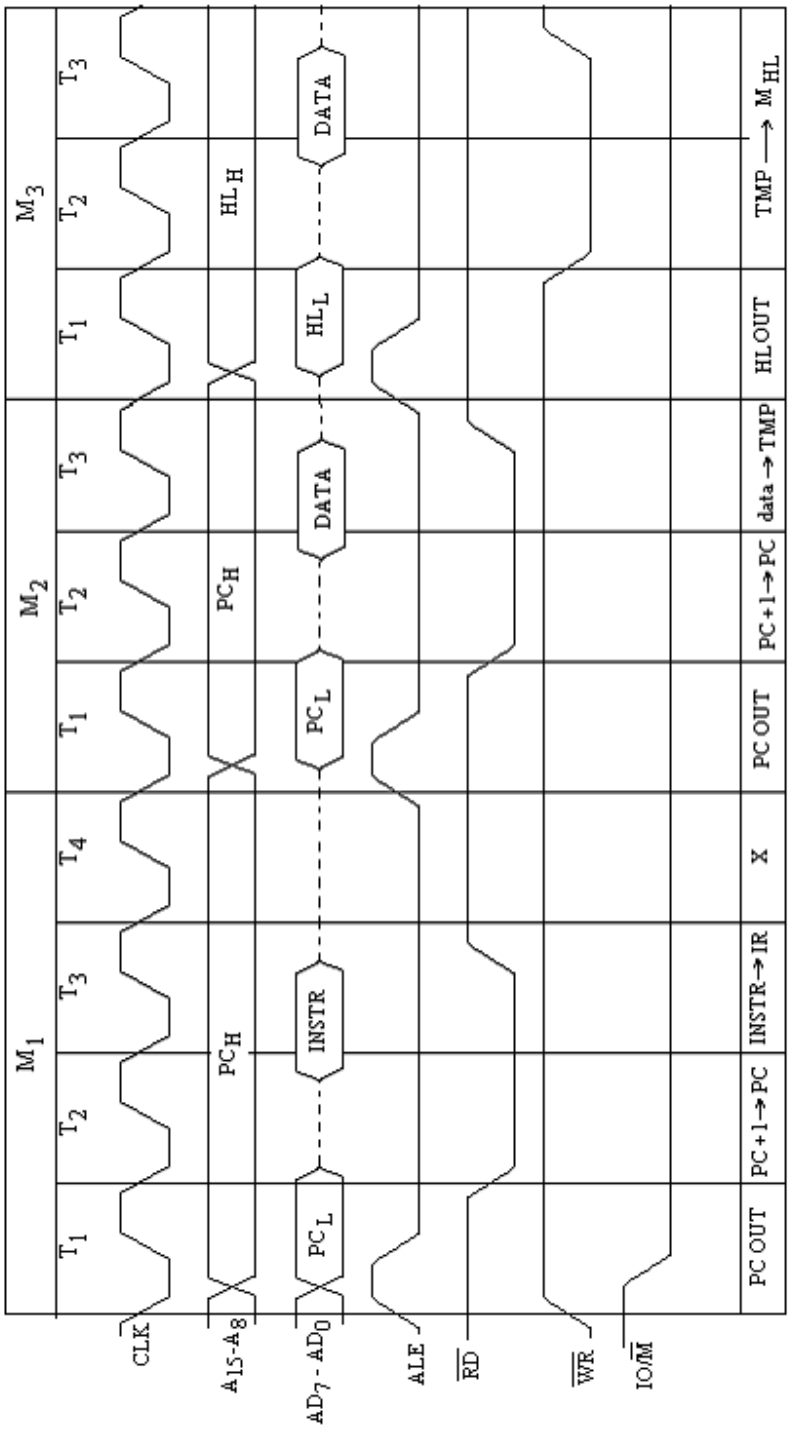

Fig. 5.13

5.4.6 Timing Diagram of *XCHG*

Let us discuss the timing diagram of one byte instruction XCHG. Its timing diagram is shown in figure 5.14. It exchanges the contents of H-L register pair with contents of D-E register pair.

The operation of M_1 machine cycle of this instruction is similar to other instructions discussed above. In this instruction the contents of H-L and D-E register pairs are to be exchanged, so address bus and address data bus are not needed. For this the operation FEO (Fetch Execute Overlap) occurs and as usual the next instruction is fetched from the memory for the M_2 machine cycle. However, during T_2 state of this machine cycle the contents of H-E and D-E pairs are exchanged ($H-L \leftrightarrow D-E$).

Because of FEO, XCHG instruction is considered to take one machine cycle with 4 T-states.

XCHG

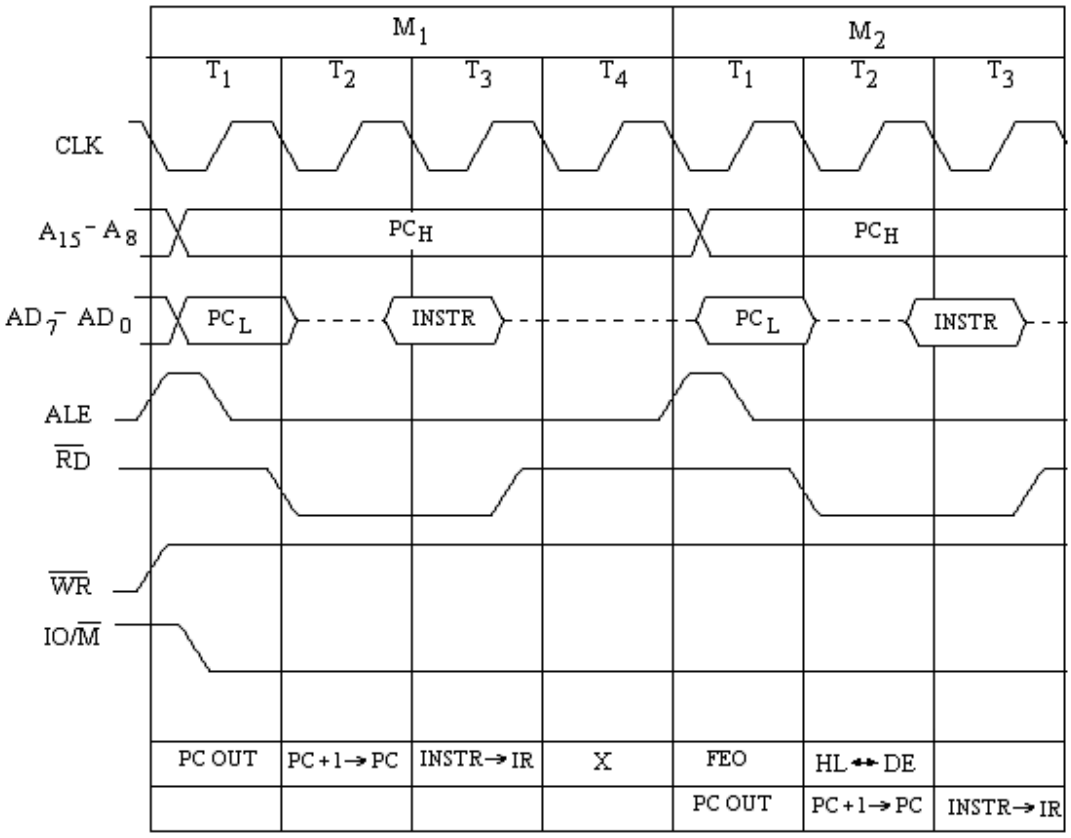

Fig. 5.14

5.4.7 Timing Diagram of *LXI rp, dbyte*

The timing diagram of 3-byte instruction ***LXI rp, dbyte*** is shown in figure 5.15. It loads the low byte of dbyte (double byte data) to the lower register of the given register pair *rp* and high byte to the high register of *rp*. This instruction takes three memory cycles with 10 T-states. First machine cycle is the op code fetch cycle which fetches the

op code of the instruction using the same procedure as discussed above for the other examples.

LXI rp, data

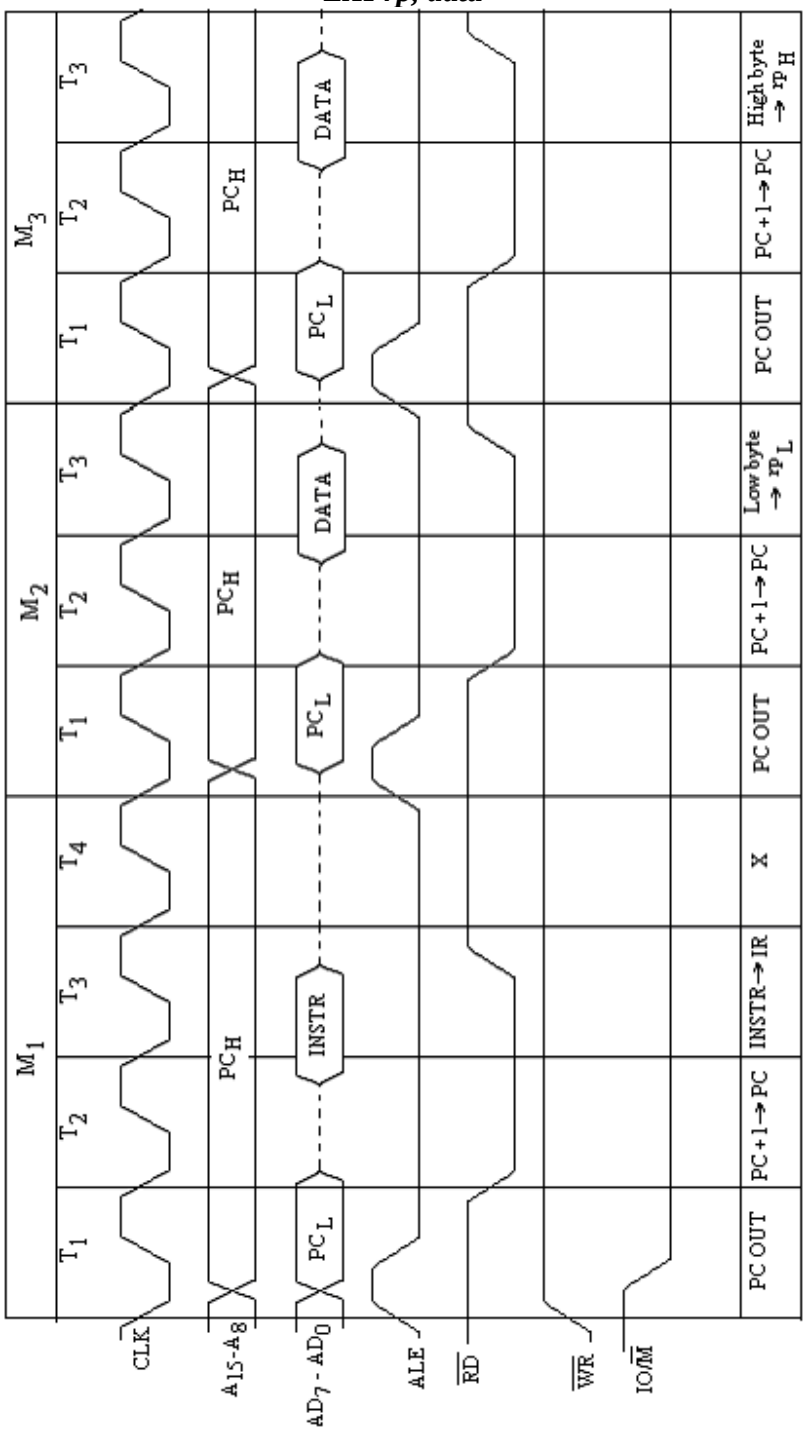

Fig. 5.15

In the T_1-state of the second machine cycle, address bus and address data bus are used to fetch the second byte (low byte of dbyte), for which ALE is enable at the beginning to the middle of this T-state. During T_2 state of M_2, PC is incremented and at T_3-state low byte of the dbyte is stored in lower register of *rp* (Low byte $\rightarrow rp_L$). This is a read cycle so $\overline{RD}$ is low at the beginning of this T-state to the middle of T_3 state. Same operation as for M_2 is, therefore, performed during M_3 machine cycle so that high byte of dbyte is stored in high register of register pair rp (High byte $\rightarrow rp_H$).

5.4.8 Timing Diagram of *IN byte*

The timing diagram of ***IN byte*** shown in figure 5.16 will now be discussed. This is an I/O read cycle and the microprocessor reads the data available at an input port or input device. The address of the port is of one byte given with the instruction. The data read out from the output port will be placed in the accumulator (A). This instruction is a two byte long and takes three memory cycles with 10 T-states. First machine cycle is an op code fetch cycle, the second is memory read cycle and the third is output read cycle.

We are familiar with the op code fetch cycle M_1. So the discussion will be made for the second and third machine cycles. In the T_1-state of second machine cycle M_2, the address of PC (incremented address) will be latched into the memory chips. At the beginning of T_1 state ALE sends a high pulse. During the T_2-state PC is incremented ($PC+1 \rightarrow PC$). Near the end of T_2-state of M_2, a byte appears on address data bus. During the T_3-state of M_2 machine cycle, this byte is copied in the W and Z registers (byte $\rightarrow$ Z, W), i.e. W and Z registers have the same byte. This byte is port address which is of 8 bits.

During T_1-state of the third machine cycle M_3, $IO/\overline{M}$ signal goes high which enables the peripheral chips for an I/O operation rather than memory operation. During this T-state, the contents of W-register are placed on the address bus and the contents of Z-register on address data bus (WZ OUT). In case of I/O device or I/O port the address is only of 8 bit long and therefore, the address of I/O device is duplicated on both address bus and address data bus. During T_2-state of M_3 cycle, $\overline{RD}$ signal goes low which indicates that it is I/O read operation. The data read out from the input port (input device) will be copied in the accumulator during T_2 and T_3 states.

PROBLEMS

1. Draw and discuss the architecture of 8085 microprocessor.
2. Mention various flags provided in 8085 microprocessor and discuss their roles.
3. Discuss the functions of program counter, Stack pointer and status flags in the architecture of 8085 microprocessor.
4. Discuss the role of address buffer and address data buffer in the architecture of 8085 microprocessor.
5. Discuss the functions of the following signals of 8085 microprocessor:
   ALE, $\overline{WR}$, $\overline{RD}$, S_0 and S_1.
6. Discuss *LHLD address*, *SHLD address*, *LDAX rp* and *STAX rp* instructions of 8085.
7. Discuss the following instructions of 8085
   XCHG, XTHL, SPHL and PCHL
   Which flags are affected by these instructions?
8. Discuss DAA instructions of 8085. Explain how flags are affected with this instruction.
9. Draw and discuss the timing diagram of *MOV reg2, reg1*.
10. Draw and discuss the timing diagram of *MOV reg, M.*
11. Draw and discuss the timing diagram of *MOV M, reg.*
12. Draw and discuss the timing diagram of *MVI reg, data.*
13. Draw and discuss the timing diagram of *MVI M, data.*
14. Draw and discuss the timing diagram of *LXI rp, dbyte.*
15. Draw and discuss the timing diagram of *XCHG.*
16. Draw and discuss the timing diagram of *IN byte.*
17. Discuss *LDAX rp* instruction of 8085. What instruction should be used to move the contents stored in memory location whose address is stored in H-L register pair.
18. What instruction should be used to store the accumulator contents to the memory location addressed by D-E register pair? Discuss that instruction in detail.
19. Discuss PCHL instruction of 8085. Explain how this instruction is said to be used as unconditional jump instruction.
20. What will be contents of accumulator and flag register, after the execution of following program:

```
MVI A, 47 H
MVI B, 37 H
ADD B
DAA
HLT
```

6

Programming of 8085

In this chapter assembly language programming of different programs will be discussed. It will help readers to go into the details of 8085 programming operations and their applications. For this, one is supposed to be well acquainted with 8085 instruction set discussed in the preceding chapters. Though some programming examples have also been discussed in these chapters, yet this chapter will exclusively deal with some more programming examples. The assembly language program written by the programmer in mnemonic form is also called as source program. The instructions, operand and data may be converted to binary (machine language) either by hand assembler or machine assembler. In case of hand assembler the hexadecimal data (op code / operand and data) are fed to the microprocessor kit through the hexadecimal key board. But in machine assembler, instructions (in mnemonic form) with data or operand are directly fed to the microprocessor kit through Alpha-numeric key board (computer key board). Here we are concerned with the assembly language program (source program).

In computers high level language like C, C++, Pascal, BASIC etc are used, which are easier than the assembly language. The computer is used for the conversion of high level language to assembly language. The advantage of using assembly language is that it can directly go into the details of the microprocessor's register and manipulate as the requirement.

6.1 SIMPLE PROGAMS

The simple programs based on the instruction set of 8085 microprocessor are given in the following examples.

Example 6.1. *Write an assembly language program of 8085 to find 1's complement of the data stored in memory location 2500 H and the result is to be stored in memory location 2501 H.*

Solution.

Program:

Label	Mnemonics	Operand	Comments
	LDA	2500 H	; Load the data from 2500 H memory location to accumulator.
	CMA		; Complement the contents of accumulator (Converts in 1's complement).
	STA	2501 H	; Store the result in memory location 2501 H.
	HLT		; Stop processing.

Example 6.2. *Write an assembly language program of 8085 to find 2's complement of the data stored in memory location 2100 H and the result is to be stored in memory location 2101 H.*

Solution.

Program:

Label	Mnemonics	Operand	Comments
	LDA	2100 H	; Load the data from 2100 H memory location to accumulator.
	CMA		; Complement the contents of accumulator (Converts in 1's complement).
	ADI	01 H	; 01 is added to the accumulator contents to get the 2's complement.
	STA	2101 H	; Store the result in memory location 2101 H.
	HLT		; Stop processing.

Example 6.3. *Write an assembly language program of 8085 to find 1's complement of n (decimal number) bytes of data stored in memory location starting at 2501 H. The number n (decimal number) is stored in memory location 2500 H. Store the result in memory locations starting at 2601 H.*

Solution.

Program:

Label	Mnemonics	Operand	Comments
	LXI D,	2601 H	; Get first address of the destination in D-E register pair.
	LXI H,	2500 H	; Get H-L pair with 2500 H.
	MOV C,	M	; Data in 2500 H is loaded to C-register which will be used as counter.
	INXH		; Increment H-L register pair.
LOOP	MOV A,	M	; Accumulator is loaded with the data.
	CMA		; Complement the contents of accumulator (Converts in 1's complement)
	STAX D		; Store the result in memory location addressed by D-E register pair.
	INX D		; Increment D-E register pair.
	INX H		; Increment H-L register pair.
	DCR C		; Decrement the C-register data.
	JNZ	LOOP	; If data in C-reg. is not zero jump to LOOP for next conversion.
	HLT		; Stop processing.

Example 6.4. *Write an assembly language program of 8085 to find 9's complement of n bytes (in BCD) of data stored in memory location starting from 2501 H. The number n*

(decimal number) is stored in memory location 2500 H. Store the result in memory locations starting from 2601 H.

Solution.

Program:

Label	Mnemonics	Operand	Comments
	LXI D,	2601 H	; Get first address of the destination in D-E register pair.
	LXI H,	2500 H	; Get H-L pair with 2500 H.
	MOV C,	M	; Data in 2500 H is loaded to C-register which will be used as counter.
	INX H		; Increment H-L register pair.
LOOP	MVI A,	99 H	; Get 99 H in accumulator.
	SUB M		; Subtract each byte by 99 H to get 9's complement.
	STAX D		; Store the result in memory location addressed by D-E register pair.
	INX D		; Increment D-E register pair.
	INX H		; Increment H-L register pair.
	DCR C		; Decrement the C-register data.
	JNZ	LOOP	; If data in C-reg. is not zero jump to loop for next conversion.
	HLT		; Stop processing.

It is clear from this example that for 9's complement each BCD byte is subtracted from 99.

Example 6.5. *Write an assembly language program of 8085 to find 2's complement of a 16 bit number stored in memory locations 2101 H and 2102 H. The least significant byte is in 2101 H. The result is to be stored in memory locations 2103 H and 2104 H.*

Solution.

Program:

Label	Mnemonics	Operand	Comments
	LXI H,	2101 H	; Get H-L pair with 2101 H.
	MVI B,	00 H	; Store 00 to register B which will be used to store carry.
	MOV A,	M	; Accumulator is loaded with the data.
	CMA		; Complement the contents of accumulator (Converts in 1's complement).
	ADI	01 H	; Add 01 H to the accumulator content to get 2's complement.
	STA	2103 H	; Store the result in memory location 2103 H.
	JNC	NXT	; If there is no carry jump to NXT.
	INR B		; Increment 1 to B-register as carry.

```
NXT     INX H                   ; Increment H-L register pair for the
                                  second byte.
        MOV A,      M           ; Move the second byte to
                                  accumulator.
        CMA                     ; Complement the contents of
                                  accumulator.
        ADD B                   ; Add carry stored in register B.
        STA         2504 H      ; Store in 2504 H.
        HLT                     ; Stop processing.
```

From this example it is clear that 1 is added to the 1's complement of LS byte and to the 1's complement of MS byte 1 is added if there is a carry from the previous byte.

Example 6.6. *Write an assembly language program of 8085 to find 10's complement of a 16 bit number (BCD) stored in memory locations 2101 H and 2102 H. The least significant byte is in 2101 H. The result is to be stored in memory locations 2103 H and 2104 H.*

Solution.

Program:

```
Label   Mnemonics   Operand     Comments
        LXI  H,     2101 H      ; Get H-L pair with 2101 H.
        MVI B,      00 H        ; Store 00 to register B which will be
                                  used to store carry.
        MVI A,      99 H        ; Store 99 in accumulator
        SUB M                   ; Subtract each byte by 99 H to get
                                  9's complement.
        ADI         01 H        ; Add 01 H to the accumulator
                                  content to get 10's complement.
        STA         2103 H      ; Store the result in memory location
                                  2103 H.
        JNC         NXT         ; If there is no carry jump to NXT.
        INR B                   ; Increment 1 to B-register as carry.
NXT     INX H                   ; Increment H-L register pair for the
                                  second byte.
        MVI A,      99 H        ; Store 99 in accumulator
        SUB M                   ; Subtract each byte by 99 H to get
                                  9's complement.
        ADD B                   ; Add carry stored in register B.
        STA         2104 H      ; Store in 2104 H.
        HLT                     ; Stop processing.
```

From this example it is clear that 1 is added to the 9's complement of LS byte and to the 9's complement of MS byte 1 is added if there is a carry from the previous byte.

Example 6.7. *Write an assembly language program of 8085 to find 2's complement of N bytes ($N \geq 2$). The number of bytes N in hexadecimal is stored in 2100 H. The bytes are stored in memory locations starting at 2101 H. The least significant byte is in 2101 H. The result is to be stored in memory locations starting at 2201 H.*

Solution.

Program:

Label	Mnemonics	Operand	Comments
	LXI H,	2100 H	; Get H-L pair with 2100 H.
	LXI D,	2201 H	; Get D-E pair with 2201 H.
	MOV C,	M	; Get the number N in c-register to be used as counter.
	INX H		; Increment H-L pair.
	MOV A,	M	; Accumulator is loaded with first data.
	CMA		; Complement the contents of accumulator (Converts in 1's complement).
	ADI	01 H	; Add 01 H to the accumulator content to get 2's complement.
	STAX D		; Store the result in memory location addressed by D-E pair.
	JNC	NXT	; If there is no carry jump to NXT.
	MVI B,	01 H	; Store 01 to B-register as carry.
	JMP	NXT1	; Jump to NXT1.
NXT	MVI B,	00 H	; Store 00 to B-register as carry.
NXT1	DCR C		; Decrement C-reg.
LOOP	INX H		; Increment H-L pair.
	INX D		; Increment D-E pair.
	MOV A,	M	; Move the next byte to accumulator.
	CMA		; Complement the contents of accumulator.
	ADD B		; Add carry stored in register B.
	STAX D		; Store in the memory location addressed by D-E pair.
	JNC	NXT2	; If there is no carry jump to NXT2.
	MVI B,	01 H	; Store 01 to B-register as carry.
	JMP	NXT3	; Jump to NXT3.
NXT2	MVI B,	00 H	; Store 00 to b-register as carry.
NXT3	DCR C		; Decrement C-reg.
	JNZ	LOOP	; If not zero jump to LOOP.
	HLT		; Stop processing.

Example 6.8. *Write an assembly language program of 8085 to find 10's complement of N bytes ($N \geq 2$). The number of bytes N in hexadecimal is stored in 2100 H. The bytes are stored in memory locations starting at 2101 H. The least significant byte is in 2101 H. The result is to be stored in memory locations starting at 2201 H.*

Solution.

Program:

Label	Mnemonics	Operand	Comments
	LXI H,	2100 H	; Get H-L pair with 2100 H.
	LXI D,	2201 H	; Get D-E pair with 2201 H.

```
        MOV C,    M       ; Get the number N in c-register to be
                            used as counter.
        INX  H              ; Increment H-L pair.
        MVI A,    99 H      ; Accumulator is loaded with 99 H.
        SUB M               ; Get the 9's Complement of the
                            number stored in location
                            addressed by H-L pair.
        ADI       01 H      ; Add 01 H to the accumulator
                            content to get 2's complement.
        STAX D              ; Store the result in memory location
                            addressed by D-E pair.
        JNC       NXT       ; If there is no carry jump to NXT.
        MVI B,    01 H      ; Store 01 to B-register as carry.
        JMP       NXT1      ; Jump to NXT1.
NXT     MVI B,    00 H      ; Store 00 to b-register as carry.
NXT1    DCR C               ; Decrement C-reg.
LOOP    INX  H              ; Increment H-L pair.
        INX  D              ; Increment D-E pair.
        MVI A,    99 H      ; Get 99 in accumulator.
        SUB M               ; Get 9's Complement of the
                            contents of accumulator.
        ADD B               ; Add carry stored in register B to
                            get 10's complement.
        STAX  D             ; Store in the memory location
                            addressed by D-E pair.
        JNC       NXT2      ; If there is no carry jump to NXT2.
        MVI B,    01 H      ; Store 01 to B-register as carry.
        JMP       NXT3      ; Jump to NXT3.
NXT2    MVI B,    00 H      ; Store 00 to b-register as carry.
NXT3    DCR C               ; Decrement C-reg.
        JNZ       LOOP      ; If not zero jump to LOOP.
        HLT                 ; Stop processing.
```

Example 6.9. *Write an assembly language program of 8085 to combine two hex nibbles stored in 2500 H and 2501 H memory locations, to form a byte. The least significant nibble is stored in 2500 H and most significant nibble is stored in 2501 H. The byte thus combined should be stored in 2502 H. (Let 08 H is stored in 2500 H and 09 H is stored in 2501 H, after the program is executed 2502 H should be loaded with the combined byte 89 H).*

Solution.

Program:

```
Label   Mnemonics  Operand   Comments
        LXI  H,    2500 H    ; Get H-L pair with 2500 H.
        MOV A,     M         ; Data in 2500 H is loaded to
                             Accumulator.
        RLC                  ; Rotate left
```

```
        RLC                     ; Rotate left
        RLC                     ; Rotate left
        RLC                     ; Rotate left (Rotated left four times
                                  so that it is moved to MS nibble).
        INX H                   ; Increment H-L register pair.
        ORA M                   ; Oring of two nibbles combines
                                  them to form a byte in
                                  accumulator.
        INX H                   ; Increment H-L register pair.
        MOV M,      A           ; Move the accumulator content
                                  (required byte) to the memory
                                  location addressed by H-L register
                                  pair.
        HLT                     ; Stop processing.
```

Example 6.10. *Write an assembly language program of 8085 to separate a hexadecimal number into two nibbles. The hexadecimal number is stored in 2501 H memory location. The least significant nibble of the byte is to be stored in 2502 memory location and the most significant nibble is to be stored in 2503 H memory location. (Suppose 3A H is a byte stored in memory location 2501 H and the lower nibble 0A should be stored in 2502 H and 03 should be stored in 2503 H)*

Solution.

Program:

```
Label   Mnemonics   Operand     Comments
        LXI  H,     2501 H      ; Get H-L pair with 2501 H.
        MOV A,      M           ; Data in 2501 H is loaded to
                                  Accumulator.
        MOV B,      A           ; Accumulator content are also
                                  loaded to B register.
        ANI         0F H        ; Mask off the first four digits
                                  (higher nibble).
        INX H                   ; Increment H-L register pair.
        MOV M,      A           ; Lower nibble is loaded to the
                                  memory location addressed by H-L
                                  register pair.
        MOV A,      B           ; Get the byte again in the
                                  accumulator.
        ANI         F0 H        ; Mask off the lower nibble.
        INX  H                  ; Increment H-L register pair.
        MOV  M,     A           ; Higher nibble is loaded to the
                                  memory location addressed by H-L
                                  register pair.
        HLT                     ; Stop processing.
```

Example 6.11. *Write an assembly language program of 8085 to check a hexadecimal number stored in 2500 H memory location for odd or even parity. If the parity is even store data EE H to memory location 2501H otherwise store 00 H in 2501 H.*
Solution.
Program:

Label	Mnemonics	Operand	Comments
	LXI H,	2500 H	; Get H-L pair with 2500 H.
	MOV A,	M	; Data in 2500 H is loaded to Accumulator.
	ORA A		; Set the flag.
	JPE	EVEN	; Check for even parity, if parity is even jump to EVEN.
	INX H		; Increment H-L register pair.
	MVI M,	00 H	; Load 00 H to the memory location addressed by H-L register pair.
	JMP	DONE	; Jump to DONE.
EVEN	INX H		; Increment H-L register pair.
	MVI M,	EE H	; Load EE H to the memory location addressed by H-L register pair.
DONE	HLT		; Stop processing.

Example 6.12. *n (decimal number) data bytes are stored in the memory locations starting at 2501 H. Write an assembly language program of 8085 to check if 12 H is stored in any of the given locations. If any of the locations has 12 H then store 12 H in that location else load 00 H in that memory location.*
Solution.
Program:

Label	Mnemonics	Operand	Comments
	LXI H,	2500 H	; Get H-L pair with 2500 H.
	MOV C,	M	; Data in 2500 H is loaded to C reg. which is used as the counter.
LOOP	INX H		; Increment H-L register pair.
	MOV A,	M	; Load the content of M_{HL} to accumulator.
	CPI	12 H	; Compare if the accumulator data are 12 H.
	JZ	NXT	; If it is 12 H then jump to NXT.
	MVI M,	00 H	; Else load 00 H to the memory location addressed by H-L register pair.
	JMP	DONE	; Jump to DONE.
NXT	MVI M,	12 H	; Load 12 H to the memory location addressed by H-L register pair.

```
DONE    DCR C              ; Decrement the content of C-reg.
                             for next byte.
        JNZ     LOOP       ; If the contents of C-reg. are not
                             zero then jump to LOOP.
        HLT                ; Stop processing.
```

Example 6.13. *16 data bytes are stored in memory locations 2001 H to 2010 H. Write an assembly language program of 8085 to transfer this block of data bytes to memory locations 2501 to 2510 H.*

Solution.

Program:

Label	Mnemonics	Operand	Comments
	LXI H,	2001 H	; Get H-L pair with 2001 H.
	LXI D,	2501 H	; Get the address of the memory location (destination) in D-E register pair
	MVI C,	10 H	; Get 10 H (16_{10}) Data in C register which is used as the counter.
LOOP	MOV A,	M	; Load the content of M_{HL} to accumulator.
	STAX D		; Load the content of accumulator to the memory locations addressed by D-E register pair.
	INX H		; Increment H-L register pair.
	INX D		; Increment D-E register pair.
	DCR C		; Decrement the content of C-reg. for next byte.
	JNZ	LOOP	; If the contents of C-reg. are not zero then jump to LOOP.
	HLT		; Stop processing.

Example 6.14. *16 data bytes are stored in memory locations 2001 H to 2010 H. Write an assembly language program of 8085 to transfer this block of data bytes to memory locations 2501 to 2510 H in the reverse order (i.e. the data of 2001 is to transferred to 2510 H and data of 2002 H to 250F H and so on).*

Solution.

Program:

Label	Mnemonics	Operand	Comments
	LXI H,	2001 H	; Get H-L pair with 2001 H.
	LXI D,	2510 H	; Get the address of the memory location (destination) in D-E register pair
	MVI C,	10 H	; Get 10 H (16_{10}) Data in C register which is used as the counter.

```
LOOP    MOV A,    M       ; Load the content of M_HL to accumulator.
        STAX D            ; Load the content of accumulator to the memory locations addressed by D-E register pair.
        INX H             ; Increment H-L register pair.
        DCX D             ; Decrement D-E register pair.
        DCR C             ; Decrement the content of C-reg. for next byte.
        JNZ       LOOP    ; If the contents of C-reg. are not zero then jump to LOOP.
        HLT               ; Stop processing.
```

Example 6.15. *Write an assembly language program of 8085 to clear the memory locations starting at 2001 (i.e. each location should have 00 H). The length of data bytes is given in 2000 H memory location.*

Solution.

Program:

```
Label   Mnemonics   Operand   Comments
        LXI  H,     2000 H    ; Get H-L pair with 2000 H.
        MOV C,      M         ; Use C register as counter.
        XRA A                 ; Clear the accumulator.
LOOP    INX H                 ; Increment H-L register pair.
        MOV M,      A         ; Load the accumulator content to the memory location.
        DCR C                 ; Decrement the content of C-reg. for next byte.
        JNZ         LOOP      ; If the contents of C-reg. are not zero then jump to LOOP.
        HLT                   ; Stop processing.
```

Example 6.16. *Write an assembly language program of 8085 to add five bytes of data stored in memory locations starting at 2000 H. If the sum generates a carry, stop addition and store 01 H to the memory location 2501 H; else continue addition and store the sum at 2501 memory location..*

Solution.

Program:

```
Label   Mnemonics   Operand   Comments
        LXI  H,     2000 H    ; Get H-L pair with 2000 H.
        MVI C,      05 H      ; Store the number of data bytes in C register as counter.
        XRA A                 ; Clear the accumulator and CY flag.
LOOP    ADD M                 ; Add the byte in accumulator.
```

	JC	NXT	; If there is a carry jump to NXT.
	INX H		; Increment the H-L register pair.
	DCR C		; Decrement the content of C-reg. for next byte.
	JNZ	LOOP	; If the contents of C-reg. are not zero then jump to LOOP.
	STA	2501 H	; Store the sum in memory location 2501 H.
	HLT		; Stop processing.
NXT	MVI A,	01 H	; If carry occurs load 01 to accumulator.
	STA	2501 H	; Store 01 H to 2501 H.
	HLT		; Stop processing.

Example 6.17. *Write an assembly language program of 8085 to add five bytes of data stored in memory locations starting at 2000 H. The sum may be more than one byte. Store the result at two consecutive memory locations2500 H and 2501 H.*

Solution.

Program:

Label	**Mnemonics**	**Operand**	**Comments**
	LXI H,	2000 H	; Get H-L pair with 2000 H.
	MVI C,	05 H	; Store the number of data bytes in C register as counter.
	XRA A		; Clear the accumulator and CY flag.
	MOV B,	A	; Store the accumulator contents to B-register also for the carry.
LOOP	ADD M		; Add the byte in accumulator.
	JNC	NXT	; If there is a no carry jump to NXT.
	INR B		; Increment B as carry is generated.
NXT	INX H		; Increment the H-L register pair.
	DCR C		; Decrement the content of C-reg. for next byte.
	JNZ	LOOP	; If the contents of C-reg. are not zero then jump to LOOP.
	LXI H,	2500 H	; Store H-L pair with 2500 H (destination address).
	MOV M,	A	
	INX H		; Store the sum to 2500 H.
	MOV M,	B	; Content of B are stored in 2501 H.
	HLT		; Stop processing.

Example 6.18. *Write a program in assembly language of 8085 to test 6^{th} bit (D_6 bit) of a byte stored at 2500 H memory location. If the bit D_6 is zero then store 00 H at 2501 H else store the same number at 2501 H.*

Solution.

Program:

Label	Mnemonics	Operand	Comments
	LXI H,	2500 H	; Get H-L pair with 2500 H.
	MOV A,	M	; Store the byte in accumulator
	ANI	40 H	; Reset all the bits except D_6.
	JZ	END	; If this bit is zero jump to END.
	MOV A,	M	; Store the byte in accumulator again.
	INX H		; Increment H-L pair.
	MOV M,	A	; The byte is stored in 2501 H.
	HLT		; Stop processing.
END	XRA A		; Clear accumulator.
	INX H		; Increment H-L pair.
	MOV M,	A	; 00 H is stored in 2501 H.
	HLT		; Stop processing.

Example 6.19. *Write an ALP (Assembly Language Program) of 8085 to find logical OR and exclusive OR of two numbers stored at 2501 H and 2502 H memory locations. The results should be stored at 2503 H (logical OR operation) and 2504 H (XOR operation) memory locations.*

Solution.

Program:

Label	Mnemonics	Operand	Comments
	LXI H,	2501 H	; Get H-L pair with 2501 H.
	MOV B,	M	; Store the byte in B-register.
	MOV A,	B	; Store this byte in accumulator also.
	INX H		; Increment H-L pair.
	MOV C,	M	; Store second byte to C register.
	ORA C		; Logical OR of two bytes.
	INX H		; Increment H-L pair.
	MOV M,	A	; Store the result (OR) in 2503 H.
	MOV A,	B	; Load the first number in accumulator.
	XRA C		; Ex-OR the two number.
	INX H		; Increment H-L pair.
	MOV M,	A	; Store the result (XOR)
	HLT		; Stop processing.

Example 6.20. *Write an ALP (Assembly Language Program) for 8085 to shift an 8-bit number left by one bit. The number is stored in 2101 H memory location. The result is to be stored in 2102 H memory location.*

Solution.

Program:

Label	Mnemonics	Operand	Comments
	LDA	2101 H	; Get the number is accumulator.
	ADD A		; Shift it left by one bit.
	STA	2102 H	; Store the result in 2502 H.
	HLT		; Stop processing.

Example 6.21. *Write an ALP 8085 to shift a 16-bit number left by one bit. The number is stored in 2101 H and 2102 H memory locations. The result is to be stored in 2103 H and 2104 H memory locations.*

Solution.

Program:

Label	Mnemonics	Operand	Comments
	LHLD	2101 H	; Get the 16 bit number in H-L register pair.
	DAD H		; Shift left by one bit.
	SHLD	2103 H	; Store the result in 2103 H and 2104 H memory locations.
	HLT		; Stop processing.

6.2 PROGAMS ON CODE CONVERSION

The programs on code conversion will now be discussed.

6.2.1 BCD to Binary Conversion

Suppose we have 0 to 99 decimal numbers (BCD numbers) and we wish to convert any of these numbers to its equivalent binary number, we proceed in the following way:

For example 49 (4 x 10 + 9) is the given decimal number, its binary equivalent is ($00011\ 0001_2$ = 31 H).

Step I — Unpack the number in MSD and LSD form.
- 0000 1001 LSD in four least significant nibble in a register.
- 0000 0100 MSD in four least significant nibble in anther register.

Step II — Multiply MSD by decimal number 10.
- or MSD is added 10 times with 0000.
- So we get (4 x 10 = 0010 1000).

Step III — ADD LSD to the result of step II.
- i.e. 00101000 + 00001001 = 00110001
- Hence we get the result.

Example 6.22. *A BCD number (0 to 99) is stored in a memory location 2500 H, write an ALP of 8085 to convert the BCD number into its equivalent binary number. Store the result in 2600 H memory location.*

Solution.

Main Program:

Label	Mnemonics	Operand	Comments
	LXI SP,	XXXX H	; Initialize the stack pointer.
	LXI H,	2500 H	; Get H-L pair with 2500 H.
	LXI D,	2600 H	; Get D-E pair with 2600 H.
	MOV A,	M	; Load the byte to accumulator.
	CALL	CONV	; Call conversion subroutine program.
	STAX D		; Store the result in 2600 H.
	HLT		

Subroutine Program:

Label	Mnemonics	Operand	Comments
CONV	PUSH D		; Push the contents of D-E register pair to stack.
	PUSH H		; Push the contents of H-L register pair to stack.
	ANI	0F H	; Separate LSD
	MOV C,	A	; Store it to C-register.
	MOV A,	M	; Load the byte to accumulator again.
	ANI	F0 H	; Separate MSD.
	RRC		; Rotate right four times
	RRC		; to shift MSD to four
	RRC		; least significant nibble
	RRC		; of accumulator.
	MOV D,	A	; Store MSD to D register.
	XRA A		; Clear accumulator.
	MVI E,	0A H	; Get 0A (decimal number 10) to E-register.
SUM	ADD D		; Add MSD ten times to 00 H.
	DCR E		; Decrement C
	JNZ	SUM	; If addition not complete then move to SUM.
	ADD C		; Add LSD to 10 X MSD
	POP H		; Pop the contents of H-L pair.
	POP D		; Pop the contents of D-E pair.
	RET		; Go back to main program.

6.2.2 Binary to BCD (Unpacked) Conversion

For example binary number is 1111 1111 (FF H). Its decimal equivalent is 255_{10} having the unpacked BCD numbers as

05 (0000 0101) BCD 1
05 (0000 0101) BCD 2
02 (0000 0010) BCD 3

The procedure for converting the 8 bit binary number (0000 0000 to 1111 1111) into unpacked BCD number is given in the following steps.

Step I If the number is less than 100 go to step II. If the number is more than 100, divide the number by 100 or subtract 100 repeatedly till the reminder is less than 100. The quotient is MS BCD (BCD 3).

Step II If the number (or remainder) is less than 10, go to step III. If number is >10 < 100, then subtract 10 repeatedly till the remainder is less than 10. The quotient is BCD 2.

Step III The remainder from step II is BCD 1.

Example 6.23. *A binary number (between 00 H to FF H) is stored in a memory location 2500 H, write an ALP of 8085 to convert this number into BCD number. Store each BCD as unpacked BCD digit in the memory locations at 2601 H to 2603 H.*

Solution.

Main Program:

Label	Mnemonics	Operand	Comments
	LXI SP,	XXXX H	; Initialize the stack pointer.
	LXI H,	2500 H	; Get H-L pair with 2500 H.
	MOV A,	M	; Load the byte to accumulator.
	CALL	CONV	; Call conversion subroutine program.
	HLT		

Subroutine Program 1:

Label	Mnemonics	Operand	Comments
CONV	LXI H,	2601 H	; Get H-L pair with 2601 H.
	MVI B,	64 H	; Load 100 in B-reg.
	CALL	CONV1	; Call another subroutine program for the division by 100.
	MVI B,	0A H	; Load 10 in B-reg.
	CALL	CONV1	; Call the subroutine again for the division by 10.
	MOV M,	A	; Load the accumulator contents to the memory location.
	RET		; Go back to main program.

Subroutine Program 2:

Label	Mnemonics	Operand	Comments
CONV1	MVI M,	FF H	; Get FF H in the $M_{H\text{-}L}$.
NXT	INR M		; Increment $[M_{H-L}]$
	SUB B		; Subtract the content of B from accumulator.
	JNC	NXT	; Jump to NXT if no carry.
	ADD B		; Add the contents of B to accumulator.
	INX H		; Increment H-L register pair.
	RET		; Go back.

Example 6.24. *Write ALP of 8085 for the following statement:*

A set of three packed BCD numbers (six digits or three bytes) are stored in memory locations starting at 2500 H. The seven segment codes of the digits 0 to 9 for common cathode LED are stored in memory locations starting at 2050 H; and the answer is to be stored in memory locations starting at 2070 H.

Solution.

Main Program:

Label	Mnemonics	Operand	Comments
	LXI SP,	XXXX H	; Initialize the stack pointer.
	LXI H,	2500 H	; Get H-L pair with 2500 H.

	MVI D,	03 H	; Number of bytes to be converted is placed in D-register.
	CALL	CONV	; Call conversion subroutine program.
	HLT		

Subroutine Program 1:

Label	**Mnemonics**	**Operand**	**Comments**
CONV	LXI B,	2070 H	; Get B-C pair with 2070 H.
NXT	MOV A,	M	; Move the content of $[M_{H-L}]$to accumulator.
	ANI	F0 H	; Separate MSD.
	RRC		; Rotate right four times
	RRC		; to shift MSD to four
	RRC		; least significant nibble
	RRC		; of accumulator.
	CALL	SEGMENT	; Call subroutine program for the conversion of unpacked BCD to seven segment.
	INX B		; Increment B-C register pair.
	MOV A,	M	; Get the byte again.
	ANI	0F H	; Separate LSD.
	CALL	SEGMENT	; Call subroutine program for the conversion of unpacked BCD (LSD) to seven segment.
	INX B		; Increment B-C register pair.
	INX H		; Increment H-L register pair.
	DCR D		; Decrement the contents of D register.
	JNZ	NXT	; If the content in D register is not then jump to NXT for next byte.
	RET		; Return to main program.

Subroutine Program 2:

Label	**Mnemonics**	**Operand**	**Comments**
SEGMENT	PUSH H		; Push the contents of H-L register pair to stack.
	LXI H,	2050 H	; Get H-L pair with 2050 H.
	ADD L		; Add the content of L register to accumulator to get right location for the digit from the look-up table.
	MOV L,	A	; Store it to L-register.
	MOV A,	M	; Load the corresponding data from the look-up table to accumulator.
	STAX B		; Store the result in the memory location addressed by B-C register pair.

```
        POP H                   ; Get the contents of H-L register
                                  pair from the stack.
        RET                     ; Go back
```

DATA (in the form of look-up table) is stored in the following memory locations:

2050 H	3F H	(Digit 0)
2051 H	06 H	(Digit 1)
2052 H	5B H	(Digit 2)
2053 H	4F H	(Digit 3)
2054 H	66 H	(Digit 4)
2055 H	6D H	(Digit 5)
2056 H	7D H	(Digit 6)
2057 H	07 H	(Digit 7)
2058 H	7F H	(Digit 8)
2059 H	6F H	(Digit 9)

The 3F H data is given for the digit 0. It is clear from the figure 6.1.

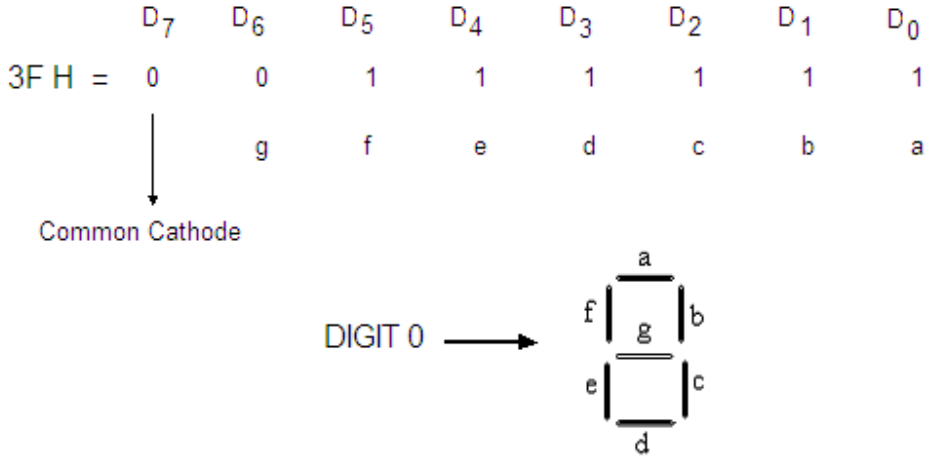

Fig. 6.1

6.2.3 Binary to ASCII Conversion

ASCII (American Standard Code for Information Interchange) is a most commonly used alphanumeric code. It is a seven bit code. The hexadecimal numbers 30 to 39 (0011 0000 to 0011 1001) represent 0 to 9 ASCII decimal numbers. Similarly, 41 H to 5A H (0100 0001 to 0101 1010) represent capital letters A to Z in ASCII.

For example, the ASCII representation of a binary number 8E is 38 H and 45 H (as 8 is represented by 0011 1000 or 38 H; and E is represented by 0100 0101 or 45 H).

The following steps are carried out for the conversion of Binary to ASCII

Step I First separate the LSD and MSD of the given binary number (or byte). Each digit is then converted to ASCII.

Step II If the digit is less than 10 (0A H) then add 30 H (0011 0000) to the binary number else add 37 H (0011 0111).

For binary number 8E H, 30 is added to 08 and we get 38 H (the ASCII Code for 8) and 37 is added to 0E H to get 45 H (the ASCII Code for E).

Example 6.25. *An eight bit binary number is stored in 2500 H. Write an ALP for 8085 to convert the binary number to its equivalent ASCII code. The ASCII code for most*

significant binary digit should be stored to 2601 H location; and the code for least significant binary digit should be stored to 2602 H location.

Solution.

Main Program:

Label	**Mnemonics**	**Operand**	**Comments**
	LXI SP,	XXXX H	; Initialize the stack pointer.
	LXI H,	2500 H	; Get H-L pair with 2500 H.
	LXI D,	2601 H	; Get D-E pair with 2601 H.
	MOV A,	M	; Move the content of $[M_{H-L}]$to accumulator.
	MOV B,	A	; Move the accumulator content to B-register.
	RRC		; Rotate right four times
	RRC		; to shift MSD to four
	RRC		; least significant nibble
	RRC		; of accumulator.
	CALL	ASCII	; Call the subroutine to convert MSD to ASCII.
	STAX D		; Store the ASCII code of MS digit to the memory location addressed by D-E register pair.
	INX D		; Increment D-E register pair.
	MOV A,	B	; Move the binary number again to accumulator.
	CALL	ASCII	; Call the subroutine to convert LSD to ASCII.
	STAX D		; Store the ASCII code of LS digit to the memory location addressed by D-E register pair.
	HLT		; Stop processing.

Subroutine Program:

Label	**Mnemonics**	**Operand**	**Comments**
ASCII	ANI	0F H	; Isolate MS digit.
	CPI	0A	; Compare with 10 (0A H).
	JC	NXT	; If it less than 10, jump to NXT.
	ADI	07 H	; Else add 07 H.
NXT	ADI	30 H	; Add 30 H.
	RET		; Go back to main program.

6.2.4 ASCII to Binary Conversion

The following steps are carried out to convert the ASCII code to binary (Hex):

Step I	Subtract 30 H (0011 0000) from the given binary (Hex) number.
Step II	If the difference after subtraction in step I is less than 10, then it is the required binary (Hex) number.

Step III If the difference after subtraction in step II is more than 10 then subtract 07 also from it. This will then give the required binary (Hex) number.

Example 6.26. *An ASCII number is stored in 2500 H memory location. Write an ALP for 8085 to convert this number into its equivalent binary (Hex) number and store it to 2501 memory location.*

Solution.

Main Program:

Label	Mnemonics	Operand	Comments
	LXI SP,	XXXX H	; Initialize the stack pointer.
	LXI H,	2500 H	; Get H-L pair with 2500 H.
	MOV A,	M	; Move the content of $[M_{H-L}]$ to accumulator.
	CALL	CONV	; Call the subroutine to convert ASCII to binary.
	INX H		; Increment H-L register pair.
	MOV M,	A	; Store the binary number to required memory location.
	HLT		; Stop processing.

Subroutine Program:

Label	Mnemonics	Operand	Comments
CONV	SUI	30 H	; Subtract 30 H from accumulator.
	CPI	0A	; Compare with 10 (0A H).
	RC		; If it less than 10 go back to main program.
	SUI	07 H	; Else subtract 07 H.
	RET		; Go back to main program.

6.3 PROGAMS ON ADDITION AND SUBTRACTION

Now we shall take up the problems on BCD or decimal addition and subtraction of two bytes or multibyte. These problems are self explanatory and can be understood by considering proper logic.

Example 6.27. *Write an ALP for 8085 to add two 16-bit numbers. The augend's LS byte is stored in 2101 H and MS byte in 2102 H. The addend's LS and MS byte are stored in 2103 H and 2104 H respectively. The result is to be stored in 2105 H to 2107 H.*

Solution.

Main Program:

Label	Mnemonics	Operand	Comments
	LHLD	2101 H	; Load the H-L pair direct with the contents of 2101 H and 2102 H Locations.
	XCHG		; Exchange the contents of H-L and D-E pair.
	LHLD	2103 H	; Load the H-L pair direct with the contents of 2103 H and 2104 H Locations.

```
        MVI  C,     00 H    ; Store 00 H to C register for carry.
        DAD  D              ; Add the contents of H-L and D-E
                              register pair and result is in H-L
                              pair.
        JNC         NXT     ; If there is no carry after the
                              addition jump to NXT.
        INR  C              ; Increment the carry.
NXT     SHLD        2105 H  ; Store the contents in the required
                              locations.
        MOV  A,     C       ; Move carry to accumulator.
        STA         2107 H  ; Store carry in 2107 H.
        HLT                 ; Stop processing.
```

Example 6.28. *Write an ALP for 8085 to add two N byte numbers. The augend's bytes are stored in memory locations starting at 2101 H and the addend's bytes are stored in memory locations starting at 2201 H. The number N is stored in memory location 2100 H. The result is to be stored in the memory locations starting at 2201 H.*

Solution.

Main Program:

```
Label   Mnemonics  Operand     Comments
        LXI  H,    2100 H    ; Get H-L pair with 2100 H.
        MOV C,     M         ; Move the number N to C-register
                               for counter.
        INX  H               ; Increment the H-L pair.
        LXI  D,    2201 H    ; Get D-E pair with 2201 H.
        XRA  A               ; Clear the accumulator and carry
                               flag.
LOOP    LDAX D               ; Get the addend byte to
                               accumulator.
        ADC  M               ; Add with carry the two bytes.
        MOV  M,    A         ; Store the result in the location
                               addressed by H-L pair.
        INX  D               ; Increment the D-E pair.
        INX  H               ; Increment the H-L pair.
        DCR  C               ; Decrement C.
        JNZ        LOOP      ; If C is not zero, then jump to
                               LOOP.
        HLT                  ; Stop processing.
```

Example 6.29. *Write an ALP for 8085 to add two N byte numbers. The augend's bytes are stored in memory locations starting at 2101 H and the addend's bytes are stored in memory locations starting at 2201 H. The number N is stored in memory location 2100 H. The result should in decimal form and is to be stored in the memory locations starting at 2201 H.*

Solution.

Main Program:

```
Label   Mnemonics  Operand     Comments
```

```
        LXI  H,     2100 H      ; Get H-L pair with 2100 H.
        MOV C,      M           ; Move the number N to C-register
                                  for counter.
        INX  H                  ; Increment the H-L pair.
        LXI  D,     2201 H      ; Get D-E pair with 2201 H.
        XRA  A                  ; Clear the accumulator and carry
                                  flag.
LOOP    LDAX D                  ; Get the addend byte to
                                  accumulator.
        ADC  M                  ; Add with carry the two bytes.
        DAA                     ; Decimal adjust the accumulator for
                                  the result in decimal form.
        MOV  M,     A           ; Store the result in the location
                                  addressed by H-L pair.
        INX  D                  ; Increment the D-E pair.
        INX  H                  ; Increment the H-L pair.
        DCR  C                  ; Decrement C.
        JNZ         LOOP        ; If C is not zero, then jump to
                                  LOOP.
        HLT                     ; Stop processing.
```

It may be noted from this example that DAA (decimal adjust the accumulator) instruction is used after ADC M for the conversion of the result in decimal form.

Example 6.30. *Write an ALP for 8085 for multibyte (N bytes) subtraction. The number of bytes (N) is stored in 2100 H location. The minuend bytes are stored in the memory locations starting at 2101 H and the subtrahend bytes are stored in the memory locations starting at 2201 H. The answer should be stored in the memory locations starting at 2101 H.*

Solution.

Main Program:

```
Label   Mnemonics  Operand     Comments
        LXI  H,     2100 H      ; Get H-L pair with 2100 H.
        MOV C,      M           ; Move the number N to C-register
                                  for counter.
        INX  H                  ; Increment the H-L pair.
        LXI  D,     2201 H      ; Get D-E pair with 2201 H.
        XRA  A                  ; Clear the accumulator and carry
                                  flag.
LOOP    LDAX D                  ; Get the addend byte to
                                  accumulator.
        SBB  M                  ; Subtract with borrow the contents
                                  of [M_{H-L}] from the accumulator
                                  contents.
        MOV  M,     A           ; Store the result in the location
                                  addressed by H-L pair.
        INX  D                  ; Increment the D-E pair.
        INX  H                  ; Increment the H-L pair.
```

```
        DCR  C                  ; Decrement C.
        JNZ      LOOP           ; If C is not zero, then jump to
                                  LOOP.
        HLT                     ; Stop processing.
```

Decimal Subtraction

It may be noted from the above example that SBB M (subtract with borrow) instruction is used for the subtraction. The result will not be obtained in the decimal form as DAA instruction can not be used after Subtract instructions. For decimal subtractions, the subtrahend number should be converted to its equivalent 10's complement which will then be added to minuend.

Example 6.31. *Write an ALP for 8085 to subtract 78 from 96. The answer in decimal form should be stored in 2100 H memory location.*

Solution.

Main Program:

Label	Mnemonics	Operand	Comments
	MVI C,	96 H	; Get 96 in C register.
	MVI B,	78 H	; Get 78 in B register.
	MVI A,	99 H	; Get 99 in accumulator.
	SUB B		; Subtract the content of B-register from 99 to get the 9's complement of 78.
	INR A		; Increment accumulator to get 10's complement.
	ADD C		; Add the content of C to the accumulator.
	DAA		; Decimal adjust the accumulator, to get the answer in decimal for.
	STA	2100 H	; Store the answer in decimal form at 2100 H location.
	HLT		; Stop processing.

Example 6.32. *Write an ALP for 8085 for multibyte (N bytes) decimal subtraction. The number of bytes (N) is stored in 2100 H location. The minuend bytes are stored in the memory locations starting at 2101 H and the subtrahend bytes are stored in the memory locations starting at 2201 H. The answer obtained in decimal form should be stored in the memory locations starting at 2101 H.*

Solution.

Main Program:

Label	Mnemonics	Operand	Comments
	LXI SP,	XXXX H	; Initialize the stack pointer.
	LXI H,	2100 H	; Get H-L pair with 2100 H.
	MOV C,	M	; Move the number N to C-register for counter.
	INX H		; Increment the H-L pair.
	LXI D,	2201 H	; Get D-E pair with 2201 H.
	LDAX D		; Get the subtrahend byte in accumulator.

```
        MOV  B,     A       ; Move the accumulator content to B-
                              register.
        MVI  A,     99 H    ; Store 99 to accumulator.
        SUB  B              ; Get 9's complement of the
                              subtrahend.
        INR  A              ; Get 10's complement of the
                              subtrahend.
        ADD  M              ; Add 10's complement of the
                              subtrahend to minuend.
        DAA                 ; Give the answer in decimal form.
        PUSH PSW            ; Push the carry to stack.
        MOV  M,     A       ; Store the result in the location
                              addressed by H-L pair.
LOOP    INX  D              ; Increment the D-E pair.
        INX  H              ; Increment the H-L pair.
        LDAX D              ; Get the second number to
                              accumulator.
        MOV  B,     A       ; Store it to B-register.
        MVI  A,     99 H    ; Store 99 to accumulator.
        SUB  B              ; Get 9's complement.
        MOV  B,     A       ; Store it to B-register.
        POP  PSW            ; Get the carry of the previous
                              addition from the stack.
        MOV  A,     B       ; Get the B-register content to
                              accumulator.
        ADC  M              ; Add with carry.
        DAA                 ; Give the answer in decimal form.
        PUH  PSW            ; Store the carry to stack for further
                              addition.
        MOV  M,     A       ; Store the result in the memory
                              location addressed by H-L register
                              pair.
        DCR  C              ; Decrement the content of C-
                              register.
        JNZ         LOOP    ; If C is not zero, then jump to
                              LOOP.
        HLT                 ; Stop processing.
```

6.4 PROGAMS TO FIND LARGEST OR SMALLEST NUMBER

Example 6.33 *Write an ALP for 8085 to find the larger of two numbers stored in memory locations 2101 H and 2102 H. Store the result in memory location 2103 H.*

Solution.

Main Program:

```
Label   Mnemonics  Operand     Comments
        LXI  H,     2101 H  ; Get H-L pair with 2101 H.
        MOV  A,     M       ; Move the first number in
                              accumulator.
```

	INX H		; Increment the H-L pair.
	CMP M		; Compare the second number with first number.
	JNC	NXT	; If the accumulator content is larger then jump to NXT.
	MOV A,	M	; Else move $[M_{H-L}]$ to accumulator.
NXT	INX H		; Increment the H-L pair.
	MOV M,	A	; Store the result in the required memory location.
	HLT		; Stop processing.

Note: To get the smaller number from the given two numbers, use the instruction JC in place of JNC.

Example 6.34. *Write an ALP for 8085 to find the largest number among three numbers stored in memory locations staring at 2101 H. Store the result in memory location 2104H.*

Solution.

Main Program:

Label	**Mnemonics**	**Operand**	**Comments**
	LXI H,	2101 H	; Get H-L pair with 2101 H.
	MOV A,	M	; Move the first number in accumulator.
	INX H		; Increment the H-L pair.
	CMP M		; Compare the second number with first number.
	JNC	NXT	; If the accumulator content is larger then jump to NXT.
	MOV A,	M	; Else move $[M_{H-L}]$ to accumulator.
NXT	INX H		; Increment the H-L pair.
	CMP M		; Compare the third number with the larger of first two numbers.
	JNC	NXT1	; If the accumulator content is larger then jump to NXT1.
	MOV A,	M	; Else move $[M_{H-L}]$ to accumulator.
NXT1	INX H		; Increment the H-L pair.
	MOV M,	A	; Store the result in the required memory location.
	HLT		; Stop processing.

Example 6.35. *Write an ALP for 8085 to find the largest number among a series of N numbers stored in memory locations staring at 2101 H. The number N is stored in memory location 2100 H. Store the result in memory location 2201 H.*

Solution.

Main Program:

Label	**Mnemonics**	**Operand**	**Comments**

```
        LXI  H,     2100 H    ; Get H-L pair with 2100 H.
        MOV  C,     M         ; Store the number N in C-register
                              which will be used as the counter.
        INX  H                ; Increment the H-L pair.
        MOV  A,     M         ; Move the first number in
                              accumulator.
        DCR  C                ; Decrement count.
LOOP    INX  H                ; Increment the H-L pair.
        CMP  M                ; Compare the second number with
                              first number.
        JNC         NXT       ; If the accumulator content is larger
                              then jump to NXT.
        MOV  A,     M         ; Else move [M_{H-L}] to accumulator.
NXT     DCR  C                ; Decrement count.
        JNZ         LOOP      ; Jump to LOOP if not zero.
        STA         2201 H    ; Store the result in 2201 H.
        HLT                   ; Stop processing.
```

6.5 PROGAMS TO ARRANGE A GIVEN SERIES IN ASCENDING OR DESCENDING ORDER

Example 6.36. *Write an ALP for 8085 to arrange a series of N-numbers in descending order. The number N is stored in memory location 2100 H. The series is stored in memory location starting at 2101 H. The result is to be stored in memory locations starting at 2201 H.*

Solution.

Main Program:

```
Label   Mnemonics  Operand   Comments
        LXI  SP,    XXXX H    ; Initialize stack pointer.
        LXI  D,     2201 H    ; Get D-E pair with 2201 H.
        LXI  H,     2100 H    ; Get H-L pair with 2100 H.
        MOV  B,     M         ; Store the count N in B-register.
START   LXI  H,     2100 H    ; Get H-L pair with 2100 H.
        MOV  C,     M         ; Store the number N in C-register
                              also.
        INX  H                ; Increment the H-L pair.
        MOV  A,     M         ; Move the first number in
                              accumulator.
        DCR  C                ; Decrement count.
LOOP    INX  H                ; Increment the H-L pair.
        CMP  M                ; Compare the second number with
                              first number.
        JNC         NXT       ; If the accumulator content is larger
                              then jump to NXT.
        MOV  A,     M         ; Else move [M_{H-L}] to accumulator.
NXT     DCR  C                ; Decrement count.
        JNZ         LOOP      ; Jump to LOOP if not zero.
```

```
        STAX  D                 ; Store the largest number in
                                  memory location addressed by D-E
                                  register pair.
        CALL    SUBR            ; Call the subroutine SUBR to put
                                  00 H to the memory location where
                                  the largest number was found.
        INX  D                  ; Increment D-E register pair.
        DCR  B                  ; Decrement B.
        JNZ     START           ; Jump to START if not zero.
        HLT                     ; Stop processing.
```

Subroutine Program:

Label	Mnemonics	Operand	Comments
SUBR	LXI H,	2100 H	; Get H-L pair with 2100 H.
	MOV C,	M	; Store the number N is C-register which will be used as the counter.
AGAIN	INX H		; Increment the H-L pair.
	CMP M		; Compare the number with the largest number obtained in the main program.
	JZ	NXT	; If it is largest jump to NXT.
	DCR C		; Decrement count.
	JNZ	AGAIN	; If counts not complete jump to AGAIN.
	MVI A,	00 H	; Store 00 H to the accumulator.
	MOV M,	A	; Put 00 H to the location at which the largest number was found.
	RET		; Go back to main program.

Example 6.37. *Write an ALP for 8085 to arrange a series of N-numbers in ascending order. The number N is stored in memory location 2100 H. The series is stored in memory location starting at 2101 H. The result is to be stored in memory locations starting at 2201 H.*

Solution.

Main Program:

Label	Mnemonics	Operand	Comments
	LXI SP,	XXXX H	; Initialize stack pointer.
	LXI D,	2201 H	; Get D-E pair with 2201 H.
	LXI H,	2100 H	; Get H-L pair with 2100 H.
	MOV B,	M	; Store the count N in B-register.
START	LXI H,	2100 H	; Get H-L pair with 2100 H.

	MOV M,	A	; Put FF H to the location at which the smallest number was found.
	RET		; Go back to main program.

6.6 PROGRAMS ON MULTIPLICATION

There are two methods for multiplication of two numbers.

1. Repetitive Addition Method
2. Shift and Add Method

Repetitive Addition Method

In this method multiplicand is added by the multiplier times.

For example, we wish to multiply 8 and 4 numbers. So add 08 to 00 for four times. i.e.

```
    0 0
+   08          1 time
-------------------------
    08
+   08          2 times
-------------------------
    16
+   08          3 times
-------------------------
    24
+   08          4 times
-------------------------
    32          Answer
-------------------------
```

Shift and Add Method

For example, we wish to multiply two decimal numbers 32 and 12 as:

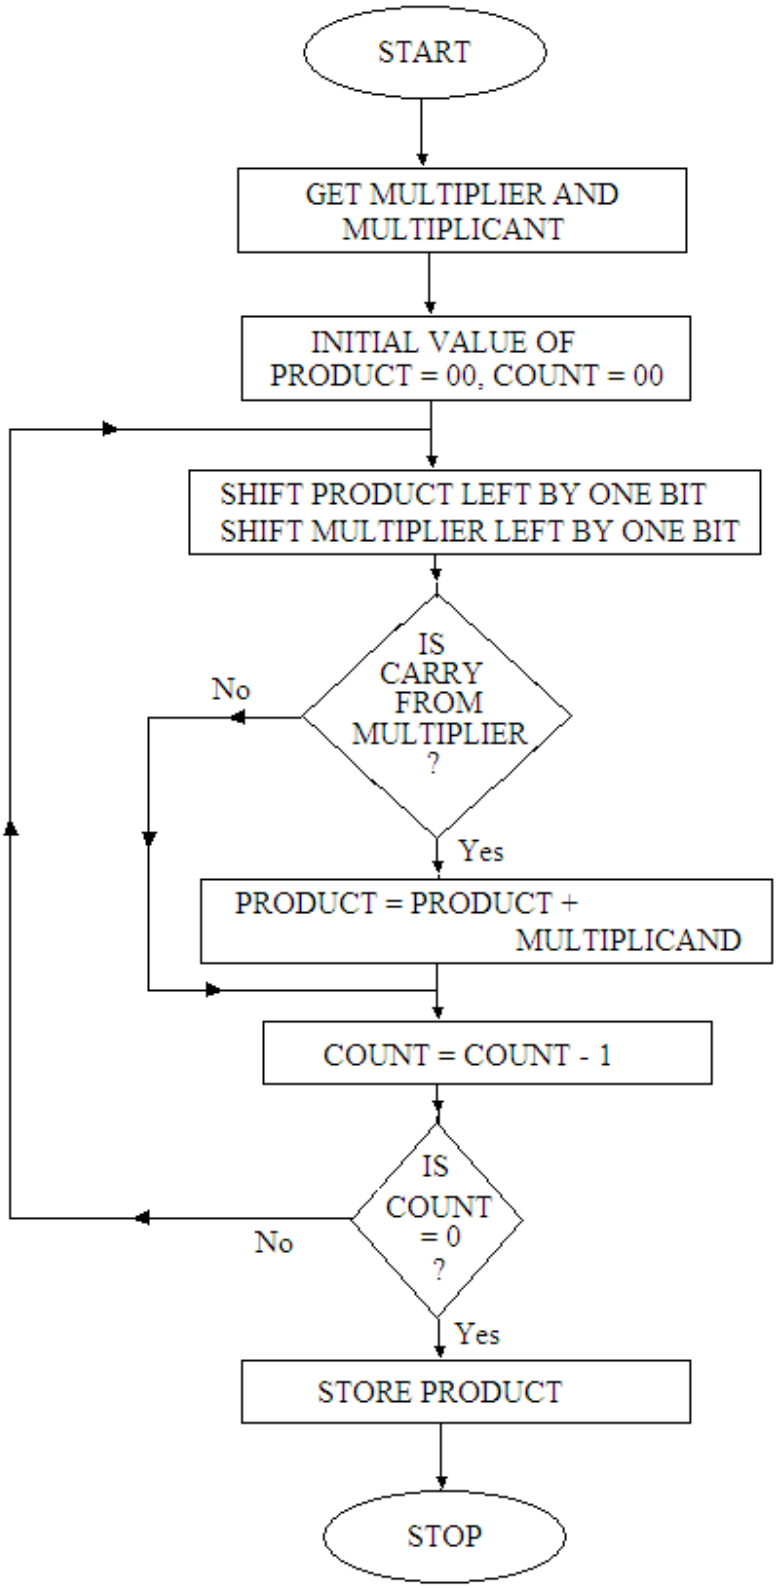
```
  3 2     Multiplicand
x 1 2     Multiplier
-----------------------
  6 4
3 2       Shift by one digit
-----------------------
3 8 4     Answer
-----------------------
```

In this example, first of all multiplicand 32 is multiplied by 2 and the result 64 is copied in the temporary register (or written on the scratch pad). Again 32 is multiplied by 1 and result 32 is shifted left by one digit to make it 32o. Now 64 and 320 are added and we get the answer 384.

Similar method used in binary multiplication. In binary multiplication, when a multiplicand is multiplied by 1, we get the product equal to multiplicand. When a multiplicand is multiplied by 0, we the product zero. For example 08 and 04 are multiplied as:

```
      0 0 0 0 1 0 0 0
    X 0 0 0 0 0 1 0 0
-----------------------
      0 0 0 0 0 0 0 0
    0 0 0 0 0 0 0 0
  0 0 0 0 1 0 0 0
0 0 0 0 0 0 0 0
0 0 0 0 0 0 0 0
0 0 0 0 0 0 0 0
0 0 0 0 0 0 0 0
-----------------------
0 0 0 0 0 0 0 0 0 0 1 0 0 0 0 0
-----------------------
```

The answer is 0020 H (32_{10}). It may be noted that the answer is not in BCD.
This method may further be illustrated using the following flow chart.



START
GET MULTIPLIER AND MULTIPLICANT
INITIAL VALUE OF PRODUCT = 00, COUNT = 00
SHIFT PRODUCT LEFT BY ONE BIT
SHIFT MULTIPLIER LEFT BY ONE BIT
IS CARRY FROM MULTIPLIER ?
No
Yes
PRODUCT = PRODUCT + MULTIPLICAND
COUNT = COUNT - 1
IS COUNT = 0 ?
No
Yes
STORE PRODUCT
STOP

Fig. 6.1

Example 6.38. *Write an ALP for 8085 to multiply any number (stored in memory location 2101 H) by 2 and store the result in 2102 H memory location.*

Solution.

Program:

Label	Mnemonics	Operand	Comments
	LXI H,	2101 H	; Get the H-L pair with 2101 H.
	MOV A,	M	; Move the number in accumulator.
	STC		; Set the carry flag.
	CMC		; Complement the carry (it clear the carry.
	RAL		; Rotate accumulator with carry i.e. it multiplies the accumulator content by two.
	INX H		; Increment the H-L pair.
	MOV M,	A	; Store the result in 2102 H memory location.
	HLT		; Stop processing.

Example 6.39. *Write an ALP for 8085 to multiply two numbers using repetitive addition method. The two numbers are in memory locations 2101 H and 2102 H. Store the result in 2103 H and 2104 H.*

Solution.

Main Program:

Label	Mnemonics	Operand	Comments
	LXI H,	2101 H	; Get H-L pair with 2101 H.
	MOV B,	M	; Get first number in B-register.
	INX H		; Increment H-L pair.
	MOV A,	M	; Get the second number in accumulator.
	CMP B		; Compare the two numbers.
	JNC	NXT	; If A < B then use A as counter.
	MVI D,	00 H	; Move 00 to D register.
	MOV E,	B	; Move first number to E register.
	JMP	NXT1	; Jump to NXT1.
NXT	MVI D,	00 H	; If A>B, so B should be used as counter.
	MOV E,	A	; Store accumulator content in E-register.
	MOV A,	B	; Store B-register content in accumulator.
NXT1	LXI H,	0000 H	; Put 00 to H and L registers.
	ORA A		; ORing of A with A to find if A = 00 H.
	JZ	END	; If zero jump to End.
	DAD D		; Add the contents of H-L pair with D-E pair and the result is in H-L pair.

```
        DCR  A                  ; Decrement count.
        JNZ      LOOP           ; If not zero jump to LOOP.
END     SHLD     2103 H         ; Store the result.
        HLT                     ; Stop processing.
```

Example 6.40. *Write an ALP for 8085 to multiply two numbers using shift and add method. The two numbers are in memory locations 2101 H and 2102 H. Store the result in 2103 H and 2104 H.*

Solution.

Main Program:

```
Label   Mnemonics   Operand     Comments
        LXI  H,     2101 H      ; Get H-L pair with 2101 H.

        RAL                     ; Rotate accumulator left to find if
                                  most significant bit is 1.
        JNC         NXT         ; If no carry jump to NXT.
        DAD  D                  ; Get Product = product +
                                  multiplicand.
NXT     DCR  B                  ; Decrement B.
        JNZ         MULT        ; If not zero jump to MULT.
        SHLD        2103 H      ; Store the result in 2103 H and
                                  2104 H .
        HLT                     ; Stop processing.
```

6.7 PROGRAM ON 8-BIT DIVISION

To divide 16 bit dividend with 8 bit divisor, the divisor is subtracted from the 8 most significant bits of the dividend. If there is no borrow, the bit of the quotient is set to 1, otherwise 0. The dividend is then shifted left by one bit before each trial of subtraction. The dividend and quotient share a register pair. Due to shift of dividend one bit of the register falls vacant in each subtraction. The quotient is stored in vacant bit positions. It is illustrated by the flow chart shown in figure 6.2.

If the dividend of the division is an 8-bit number, then it is extended to a 16-bit number by placing zeros in the MSBs positions.

Fig. 6.2

Example 6.41. *Write an ALP for 8085 to divide a 16-bit number by an 8-bit number. The dividend bytes are stored in memory locations 2101 H and 2102 H. (LS byte in 2101 H and MS byte in 2102 H). The divisor is stored in memory location 2103 H. The quotient is to be stored in the memory location 2104 H and the remainder is to be stored in the memory location 2105 H.*

Solution.

Main Program:

Label	Mnemonics	Operand	Comments
	LHLD	2101 H	; Get 16-bit dividend in H-L pair.
	LDA	2103 H	; Get divisor in accumulator.
	MVI C,	08 H	; Get count 08 in C-register.
	MVI D,	00 H	; Quotient = 00.
	MOV B,	A	; Keep the divisor in B-register also.
LOOP	DAD H		; Shift dividend left by one bit.
	MOV A,	D	; Keep the quotient in accumulator.
	ADD A		; Shift quotient left by one bit.
	MOV D,	A	; Store the quotient in D-register.
	SUB B		; Perform trial subtraction.
	JC	NXT	; If carry then dividend = previous dividend.
	MOV H,	A	; Put most significant bits of dividend in register H.
	INR D		; Increment quotient by 1.
NXT	DCR C		; Decrement C.
	JNZ	LOOP	; If not zero jump to LOOP.
	MOV L.	D	; Store the quotient in L-register.
	SHLD	2104 H	; Store the result in 2104 H and 2105 H .
	HLT		; Stop processing.

6.8 MISCELLANEOUS PROGRAMS

Example 6.42. *Write an ALP for 8085 to find the square of a given number stored in memory location 2101 H and the result is to be stored in memory location 2102 H. Use Look-up table starting at 2200 H.*

Solution.

Main Program:

Label	Mnemonics	Operand	Comments
	LXI D,	2200 H	; Get D-E pair with 2200 H (Starting address of the look-up table).
	LDA	2101 H	; Get the number in accumulator.
	MOV L,	A	: Load the number to L-register.
	MVI H,	00 H	; Get 00 H to H-register.
	DAD D		; Get effective address in H-L register pair.
	MOV A,	M	; Get the result in accumulator.

	STA	2102 H	; Store the result in the required memory location.
	HLT		; Stop processing.

Look-up table:

Location	Data
2200 H	00 H
2201 H	01 H
2202 H	04 H
2203 H	09 H
2204 H	10 H
2205 H	19 H
2206 H	24 H
2207 H	31 H
2208 H	40 H
2209 H	51 H
220A H	64 H
220B H	79 H
220C H	90 H
220D H	A9 H
220E H	C4 H
220F H	E1 H

Example 6.43. *Write an ALP for 8085 to find the square of a given number stored in memory location 2101 H and the result is to be stored in memory location 2102 H. Use the addition of successive odd integers.*

Solution.

Main Program:

Label	Mnemonics	Operand	Comments
	LDA	2101 H	; Get the number in accumulator.
	MVI L,	00H	: Load 00 H to L-register.
	ORA L		; Find if number is zero.
	JZ	END	; If number is zero then no need to find the square and jump to END.
	MOV C,	A	; Move the number to C-register.
	MOV A,	L	; Move the content of L-reg to accumulator so that square is zero.
	MVI B,	01 H	; Move 01 to B-register (first odd number).
LOOP	ADD B		; Add next odd number.
	INR B		; Find next odd number to add
	INR B		; 02.
	DCR C		; Decrement C-register contents.
	JNZ	LOOP	; Continue if not zero.
END	STA	2102 H	; Store the result in the memory location 2102 H.

```
        HLT                         ; Stop processing.
```

Example 6.44. *Write an ALP for 8085 to find the square root of a given number (perfect positive square) stored in memory location 2101 H and the result is to be stored in memory location 2102 H. Use the subtraction of successive odd integers.*

Solution.

Main Program:

Label	Mnemonics	Operand	Comments
	LDA	2101 H	; Get the number in accumulator.
	ORA A		; Find if number is zero.
	JZ	END	; If number is zero then no need to find the square root and jump to END.
	MVI B,	01 H	; Move 01 to B-register (first odd number).
	MVI C,	01 H	; Initial value of square root as one.
LOOP	SUB B		; Subtract next odd number.
	JZ	END	; If number is zero then jump to END.
	INR B		; Find next odd number to add
	INR B		; 02.
	INR C		; Decrement square root value by 1.
	JNC	LOOP	; Continue if no carry.
END	MOV A,	C	; Store the result in accumulator.
	STA	2102 H	; Store the result in the memory location 2102 H.
	HLT		; Stop processing.

Example 6.45. *Write an ALP for 8085 to find the Fibonacci series. Sixteen terms of this series are to be store in the memory locations starting at 2101 H. Let 00 H and 01 H data are stored in memory locations 2101 H and 2102 H respectively before the execution of the program.*

Solution. The terms of Fibonacci series are given as:

1, 1, 2, 3, 5, 8, 13, 21,. . . . .

This sequence is defined by assuming first two terms have the same value 1, and each term afterwards is the sum of the previous two terms, that is,

1 + 1 = 2, 1 + 2 = 3, 2 + 3 = 5, 3 + 5 = 8, and so on.

The required terms of the

Main Program:

Label	Mnemonics	Operand	Comments
	MVI C,	10 H	; Decimal number 16 (10 H) is stored in C-register which will be used as counter.
	LXI H,	2100 H	; Get H-L pair with 2100 H.
	MOV A,	M	; Move first data to accumulator.
	INX H		; Point to next data.
LOOP	ADD M		; Get next term of the series.

```
INX  H                  ; Point to the next memory location
                          for storing the next term.
MOV  M,     A           ; Store the next term.
DCX  H                  ; Get previous term of the Fibonacci
                          series.
MOV  A,     M           ; Get this term in accumulator.
INX  H                  ; Point to the next memory location.
DCR  C                  ; Decrement count.
JNZ         LOOP        ; If not zero jump to LOOP.
HLT                     ; Stop processing.
```

Data stored before the execution of the program.

2100 H	00 H
2101 H	01 H

PROBLEMS

1. Write an assembly language program of 8085 to fill the RAM area from 2500 H to 25FF H with a byte 33 H.
2. Sixteen bytes of data are stored in memory locations 2001 H to 2010 H. Write an assembly language program of 8085 to transfer this block of data to 2006 H to 2015 H.
   (Hint: In this case data will be transferred in the reverse order otherwise some of the data will coincide.)
3. Write a program (WAP) in assembly language of 8085 to compare two hexadecimal numbers, stored in 2001 H and 2002 H memory locations, for equality. If the numbers are equal, the number itself will be stored in 2003 H memory location, else 00 H will be stored in the memory location 2003 H.
4. WAP in assembly language of 8085 to test 3rd bit (D_3 bit) of a byte stored at 2000 H memory location. If the bit D3 is zero store 00 at 2101 H else store the same number at 2101 H.
5. Write an assembly language program (ALP) of 8085 to find the logical AND and Logical OR of 26 H and 39 H. Store the result in 2500 H and 2501 H.
6. Write an ALP of 8085 to load EE H to the memory locations starting at 2501 H. The length of data bytes is given in 2500 H memory location.
7. Write an ALP for 8085 to add two 8-bit numbers stored in memory locations 2101 H and 2102 H. The result should be stored in 2103 H and the carry if any should be stored in 2104 H.
8. Write an assembly language program for 8085 to add two 8 bit numbers stored in memory locations 2101 H and 2102 H. The answer is required in decimal form and it should be stored in 2103 H and the carry if any should be stored in 2104 H.
9. Write an ALP for 8085 to add 833 and 776 decimal numbers. The result should be stored in 2101 H to 2103 H memory locations. The memory location 2103 H should store the carry bit if any.
   (Hint: First convert the decimal numbers 833 and 776 to hexadecimal numbers.)
10. Write an ALP for 8085 to subtract an 8 bit number (stored in 2101 H memory location) from another 8 bit number (stored in 2102 H memory location). The

answer should be stored in 2103 H and the borrow bit if any should be stored in 2104 H.

11. Repeat the problem 10 to get the result in decimal form.
12. Write an ALP for 8085 to find smaller of two numbers stored in 2301 H and 2302 H. Store the smaller number in memory location 2303 H.
13. Write an ALP for 8085 to find the smallest of the three numbers stored in memory locations starting at 2301 H. Store he smallest number in 2304 H.
14. Write an ALP for 8085 to find the smallest number among a series of 16 numbers stored in the memory locations starting at 2301 H. The number 16 (10 H) is stored in 2300 H. The smallest number should be should be stored in 2401 H.
15. Write an ALP to find 13 terms of Fibonacci series. The terms of the series are to be stored in the memory locations starting at 2501 H.
16. Write an ALP for 8085 to shift an 8-bit number left by two bits. The number is stored in memory location 2501 H and the result is to be stored in 2502 H memory location.
    (Hint: Keep the number in accumulator and use ADD A instruction twice.)
17. Write an ALP for 8085 to shift a 16-bit number left by two bits. The number is stored in memory locations 2501 H and 2502 H. The result is to be stored in 2503 H and 2504 H memory locations.

7

Interrupt Instructions of 8085

In the preceding chapters the architecture, instruction set and programming details of 8085 microprocessor were discussed. The microprocessor forms the parts of microcomputers. Many complicated and sophisticated operations can be performed by using the microprocessor based systems. These systems have the facilities to transfer the data from the microprocessor to the outside world or vice-versa. The transfer of data takes place through the data bus with the help of address and control buses. Thus special circuitry is needed to convert data from a wide range of input devices into suitable form for microprocessor buses. The circuitries used between the microprocessor and input/output devices are known as interfaces. This chapter deals how the external devices (peripherals) get connected to the microprocessor. In addition, different ways of data transfer from the microprocessor to the peripheral devices and vice-versa, and the restart instructions will also be discussed.

7.1 METHODS OF I/O OPERATIONS

There are two ways for the transfer of data from microprocessor to I/O devices and vice-versa.

1. Memory Mapped I/O
2. I/O Mapped I/O or Isolated I/O

7.1.1 Memory Mapped I/O

Memory Mapped I/O system is used in smaller system. In this system there is only one address space, some addresses are assigned to memories and some addresses to I/O devices i.e. the addresses to I/O devices are different from the addresses which have been assigned to memories. In other words the I/O devices and memory share the memory map, with some address reserved for the I/O devices and rest for the memory. This scheme is shown in figure 7.1. The microprocessor use R/W signals to determine the direction of data flow. The main advantage of this scheme is that it does not require additional decoding circuitry and the set of instructions may be used to fetch data either from the I/O devices or from the memory locations.

Following instructions may be used for the data transfer in this scheme:

MOV M, A — It moves the contents of accumulator to M_{H-L}. If H-L pair contains the address of memory location, then the data will be transferred to memory location; if on the other hand H-L pair contains the address of the I/O devices, then the accumulator data will be transferred to I/O devices.

MOV A, M — It moves the contents of M_{H-L} to accumulator. If H-L pair contains the address of memory location, then the data will be transferred from memory location; similarly if H-L pair contains the address of the I/O devices, then the data from I/O devices will be transferred to accumulator.

STA address — It stores the contents of accumulator to addressed location. If the address represents the address of memory location then the accumulator contents will be stored to memory location; if on the other hand address represents the address of the I/O devices, then the accumulator data will be transferred to I/O devices.

LDA address — It stores the addressed contents to the accumulator. If the address represents the address of memory location then the contents stored in memory location will be transferred to accumulator; if on the other hand address represents the address of the I/O devices, then the data from the I/O devices will be transferred to the accumulator.

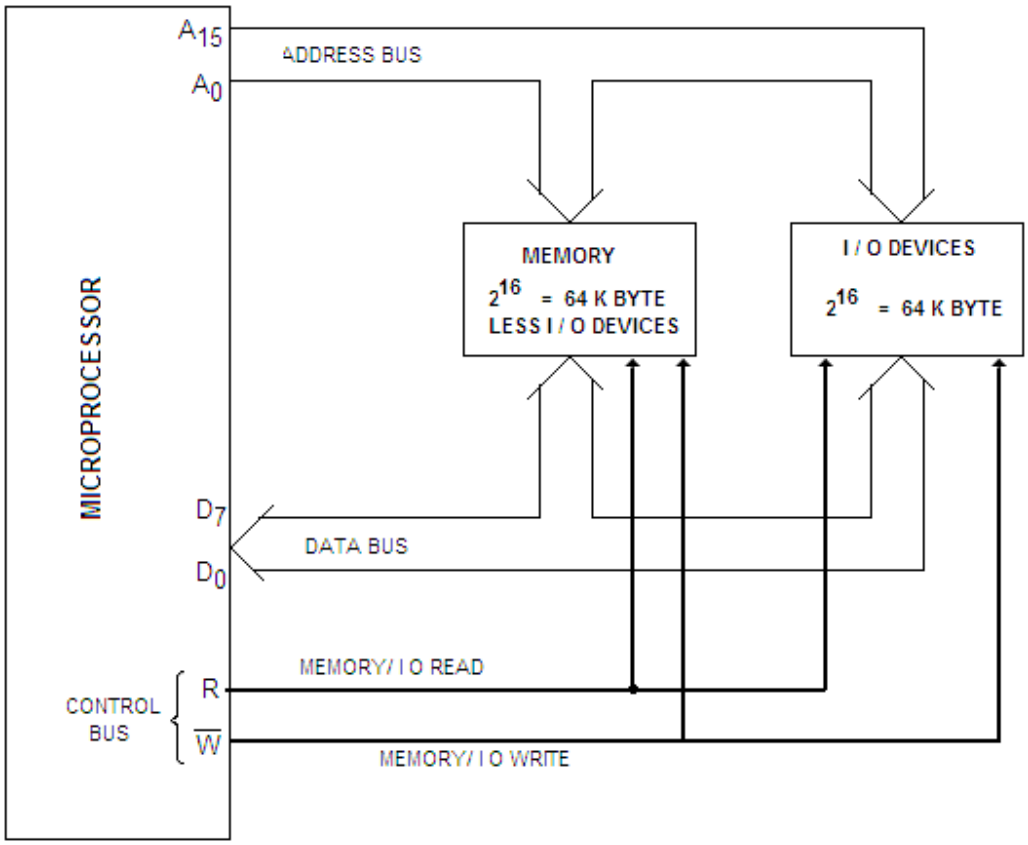

Fig. 7.1

Many other instructions like LDAX, STAX and other arithmetic and logic instructions etc may also be used in this memory mapped I/O systems.

7.1.2 I/O Mapped I/O or Isolated I/O

Larger systems use this technique for the data communication to I/O devices. Figure 7.2 shows this system used in 8085 microprocessor. In this technique the

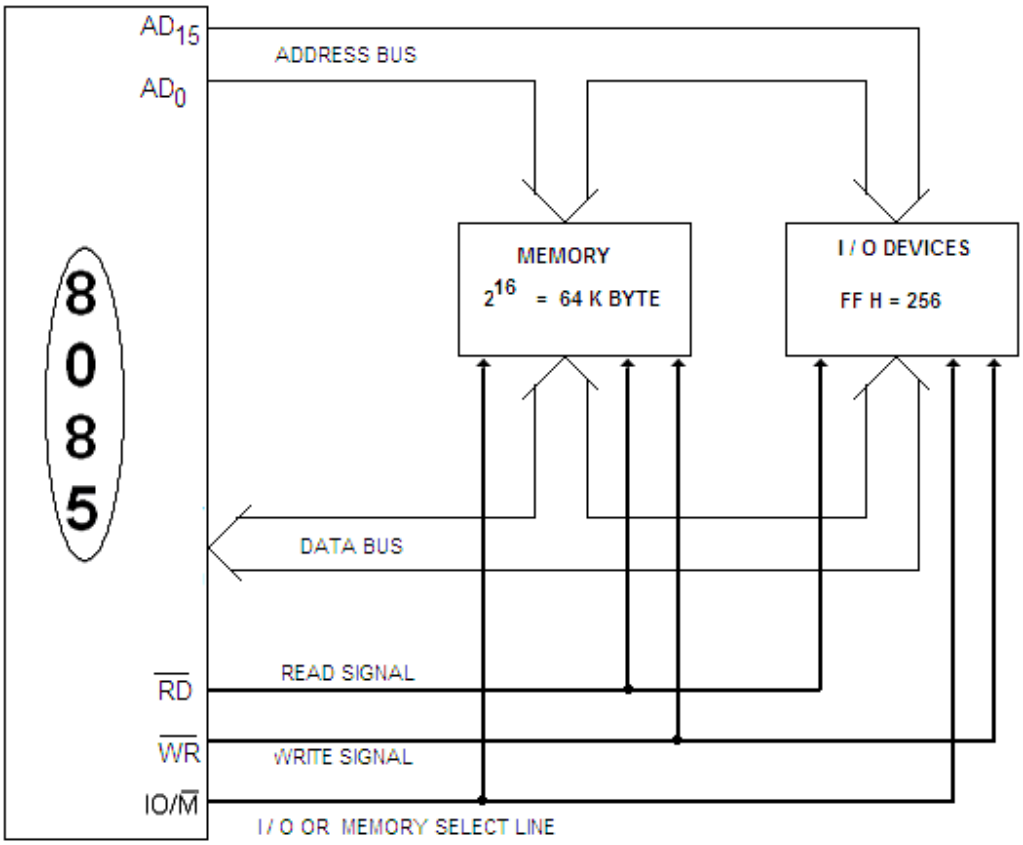

Fig 7.2

microprocessor treats the memory and I/O devices separately, using different control lines for each of them. In 8085A the $IO/\overline{M}$ signal is used for this purpose. If this signal is low (0), it represents the memory. However, if this signal is high (1), it represents the I/O operations. $\overline{RD}$ and $\overline{WR}$ signals in association with $IO/\overline{M}$ signal help in performing I/O read/write operations or memory read/write operations. Table 7.1 shows the operations of these signals.

Table 7.1

$\overline{RD}$	$\overline{WR}$	$IO/\overline{M}$	Operations	Address
0	1	0	$\overline{MEMR}$ Memory Read	$\mathbf{A_{15}}$-$\mathbf{A_0}$
1	0	0	$\overline{MEMW}$ Memory Write	$\mathbf{A_{15}}$-$\mathbf{A_0}$
0	1	1	$\overline{IOR}$ I/O Read	$\mathbf{A_7}$-$\mathbf{A_0}$
1	0	1	$\overline{IOW}$ I/O Write	$\mathbf{A_7}$-$\mathbf{A_0}$

Figure 7.3 shows the generation of $\overline{MEMR}$ (Memory Read), $\overline{MEMW}$ (Memory Write), $\overline{IOR}$ (I/O Read) and $\overline{IOW}$ (I/O Write) signals.

In this scheme, special instructions are used to perform the I/O operations. The special instructions are:

IN XX H (XX H is the Port address of 1 byte , which is in between 00 H to FF H)

OUT XX H (XX H is the Port address of 1 byte , which is in between 00 H to FF H)

The address XX H of the I/O port is duplicated on both the high and low order address bus and the signal $IO/\overline{M}$ ensures that the memory location corresponding to that address (XXXX H) does not respond.

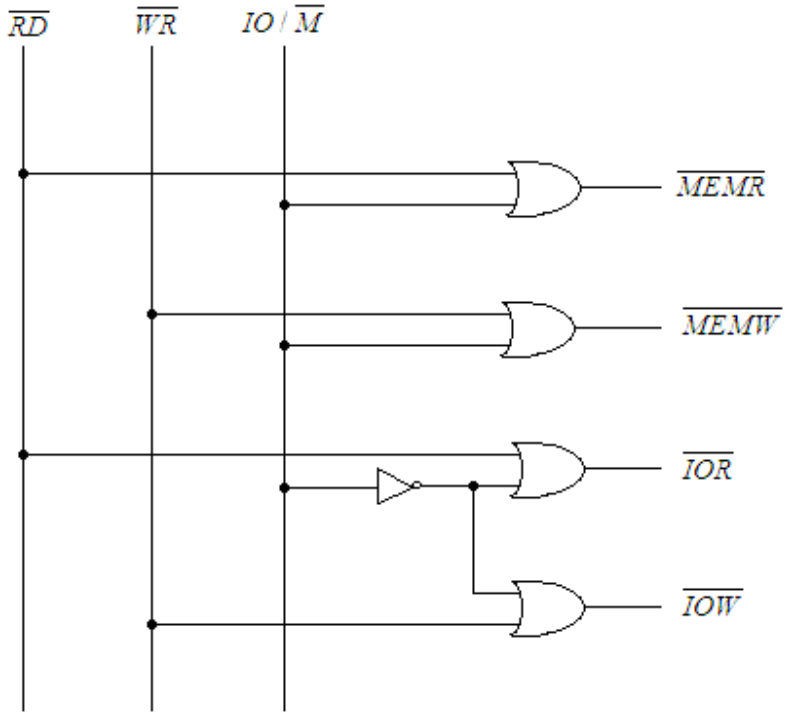

Fig. 7.3

Comparison of Memory Mapped I/O and I/O Mapped I/O is given in table 7.2.

Memory Mapped I/O	I/O Mapped I/O
1. Large Number of instructions like MOV A, M, MOV M, A, LDA, STA etc are used for the data transfer.	Only two instructions IN Port, OUT Port are used for the data transfer from microprocessor to I/O devices and vice versa.
2. Data transfer is possible between any register of C.P.U. and I/O devices.	Data transfer is possible only between Accumulator and I/O devices.
3. Arithmetic and logic operations can be performed with the data of I/O Ports using with the instructions like ORA M, XRA M, ANA M, ADD M, SUB M etc.	Arithmetic and logic operations can not be performed in this scheme.

4. Memory mapping of 64 K byte is shared between system memory and I/O ports.	256 (FF H) I/O devices may be interfaced.
5. 16-bit address lines are needed.	8-bit address lines are needed.
6. It takes different T-states depending on the instructions.	It takes 10 T-states for its execution.

7.2 DATA TRANSFER SCHEMES

In microprocessor based systems several input / output devices are connected and data transfer may take place between microprocessor and memory, microprocessor and I/O devices and memory & I/O devices. Not much of the problems arise for the data communication between microprocessor and memory as same technology is used in the manufacturing of memory and microprocessor. The speed of the memory is almost compatible with the speed of microprocessor. But for the data transfer between the microprocessor and I/O devices, the problems arise due to mismatch of the speed of the I/O devices and the speed of microprocessor or memory. To overcome the problem of speed mismatch between the microprocessor and I/O devices following data transfer schemes (fig. 7.4) may be considered. The data transfer schemes were categorized depending upon the capabilities of I/O devices for accepting serial or parallel data.

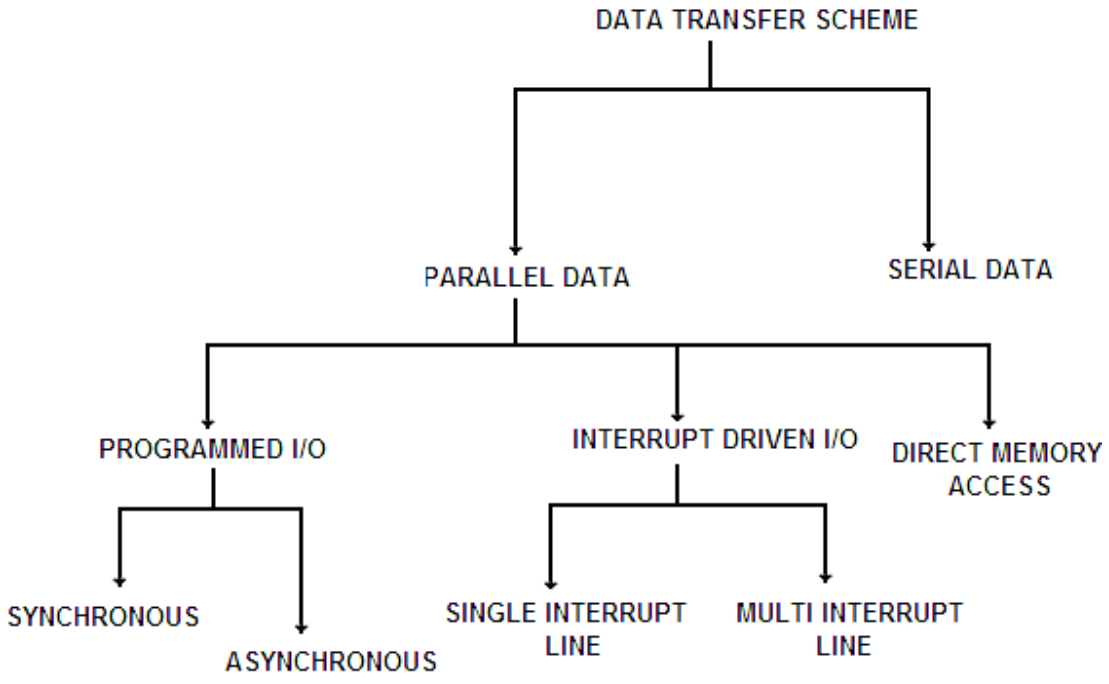

Fig. 7.4

The 8085 microprocessor is a parallel device i.e. it transfers eight bits of data simultaneously over eight data lines (parallel I/O mode). However in many situations, the parallel I/O mode is either impractical or impossible. For example, parallel data communication over a long distance becomes very expensive. Similarly, parallel data communication is not possible with devices such as CRT terminal or Cassette tape etc. For these devices, therefore, serial I/O mode is used which transfer a single bit on a single line at a tine. For serial data transmission, 8-bit parallel word is converted to a stream of eight serial bit using parallel-to-serial conversion. Similarly, in serial reception of data, the microprocessor receives a stream of 8-bit one by one which are then converted to 8-bit parallel word using serial-to-parallel conversion. The parallel data transfer will now be discussed in the following sub-sections.

7.2.1 Programmed I/O Data Transfer

This method of data transfer is generally used in the simple microprocessor systems where speed is unimportant. This method uses instructions to get the data into or out of the microprocessor. The data transfer can be synchronous or asynchronous depending upon the type and the speed of the I/O devices.

Synchronous type of data transfer can be used when the speed of the I/O devices matches with the speed of the microprocessor. The common clock pulse synchronizes the microprocessor and the I/O devices. In such data transfer scheme because of the matching of the speed, the microprocessor does not have to wait for the availability of the data; the microprocessor immediately sends data for the transfer as soon as the microprocessor issues a signal.

The asynchronous data transfer method is used when the speed of the I/O devices is slower than the speed of the microprocessor. Because of the mismatch of the speed, the

internal timing of the I/O device is independent from the microprocessor and thus two

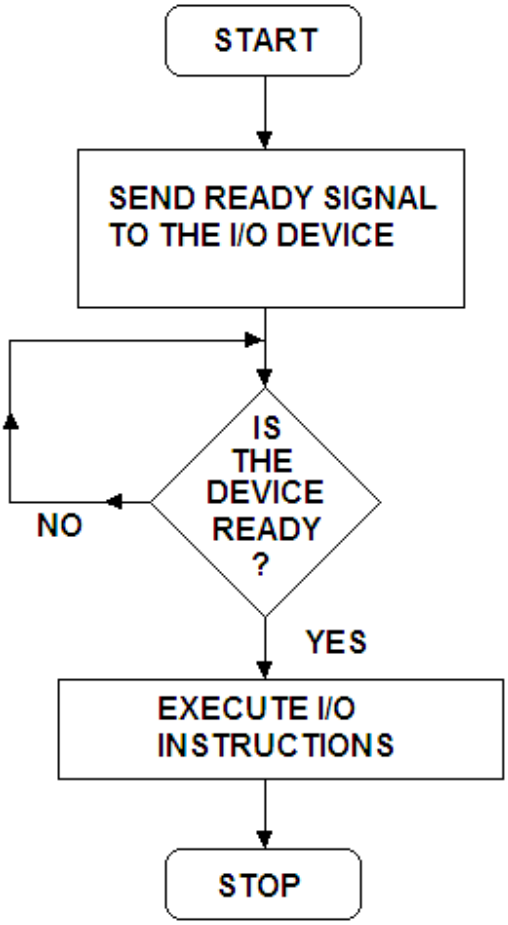

Fig. 7.5

units are said to be asynchronous to each other. The asynchronous data transfer is normally implemented using 'handshaking' mode. In the handshaking mode some signals are exchanged between the I/O device and microprocessor before the data transfer takes place. The microprocessor has to check the status to the input/output device, if the device is ready for the data transfer. The microprocessor initiates the I/O device to get ready; the status of the I/O device is continuously checked by the microprocessor till the I/O device becomes ready, the microprocessor sends instructions to transfer the data. Flow chart for this mode of data transfer is shown in figure 7.5.

Fig. 7.6 illustrates the asynchronous handshaking process to transfer the data from the microprocessor to I/O device. In this figure, the microprocessor sends a ready signal to I/O device. When the device is ready to accept the data, the I/O device sends an 'ACK' (Acknowledge) signal to microprocessor indicating that the I/O device has acknowledged the 'Ready' signal and is ready for the transfer of data.

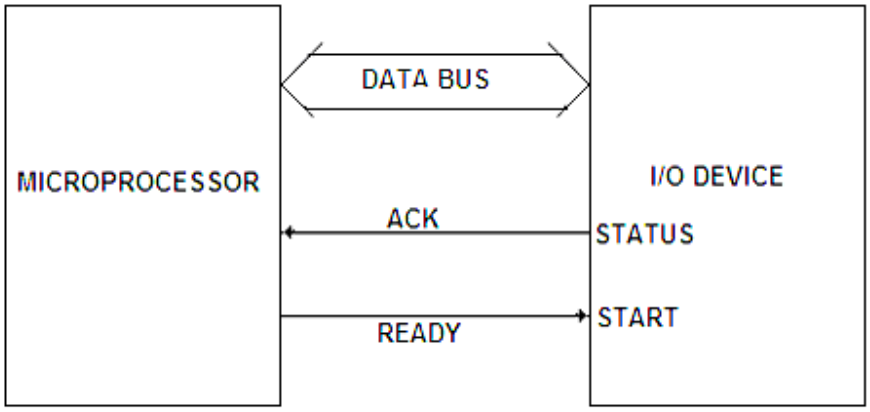

Fig. 7.6

Figure 7.7 shows the asynchronous handshaking process to transfer the data from the I/O device to microprocessor. In this case I/O device issues the ready signal to microprocessor indicating that I/O device is ready to send the data to microprocessor. In response to this signal, valid data signal is sent by the microprocessor to I/O device and then the valid data is put on the data bus for the transfer.

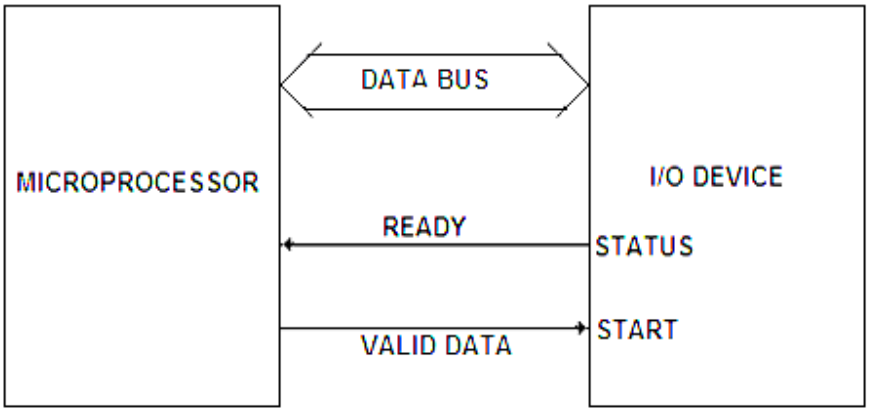

Fig. 7.7

7.2.2 Interrupt Driven I/O Data Transfer

In the programmed I/O data transfer method discussed above, the microprocessor is busy all the time in checking for the availability of data from the slower I/O devices and also in checking if I/O device is ready for the data transfer. In other words in this data transfer scheme, some of the microprocessor time is wasted in waiting while an I/O device is getting ready. The interrupt driven I/O data transfer method is efficient as no microprocessor time is wasted in waiting for an I/O device to be ready. The I/O device informs the microprocessor for the data transfer whenever the I/O device is ready. This is achieved by interrupting the microprocessor. The interrupt is hardware facilities provided on the microprocessor. In the beginning the microprocessor initiates data transfer by requesting the I/O device 'to get ready' and then continue executing its original program rather wasting its time by checking the status of I/O device. Whenever the device is ready to accept or supply data, it informs the processor through a control signal known as

interrupt signal. In response to this interrupt signal, the microprocessor sends back an interrupt acknowledge signal to the I/O device indicating that it received the request (Fig. 7.8). It then suspends its job after executing the current instruction. It saves the contents

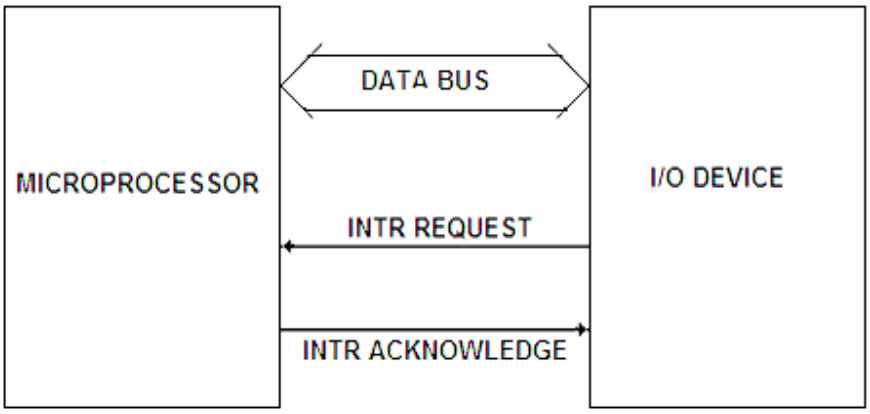

Fig. 7.8

of program counter and status to stack and jumps to the subroutine program. This subroutine program is called Interrupt Service Subroutine (ISS) program. The ISS saves the processor status into stack; and after executing the instruction for the data transfer, it restores the processor status and then returns to main program. The flow chart for this method of data transfer is shown in figure 7.9.

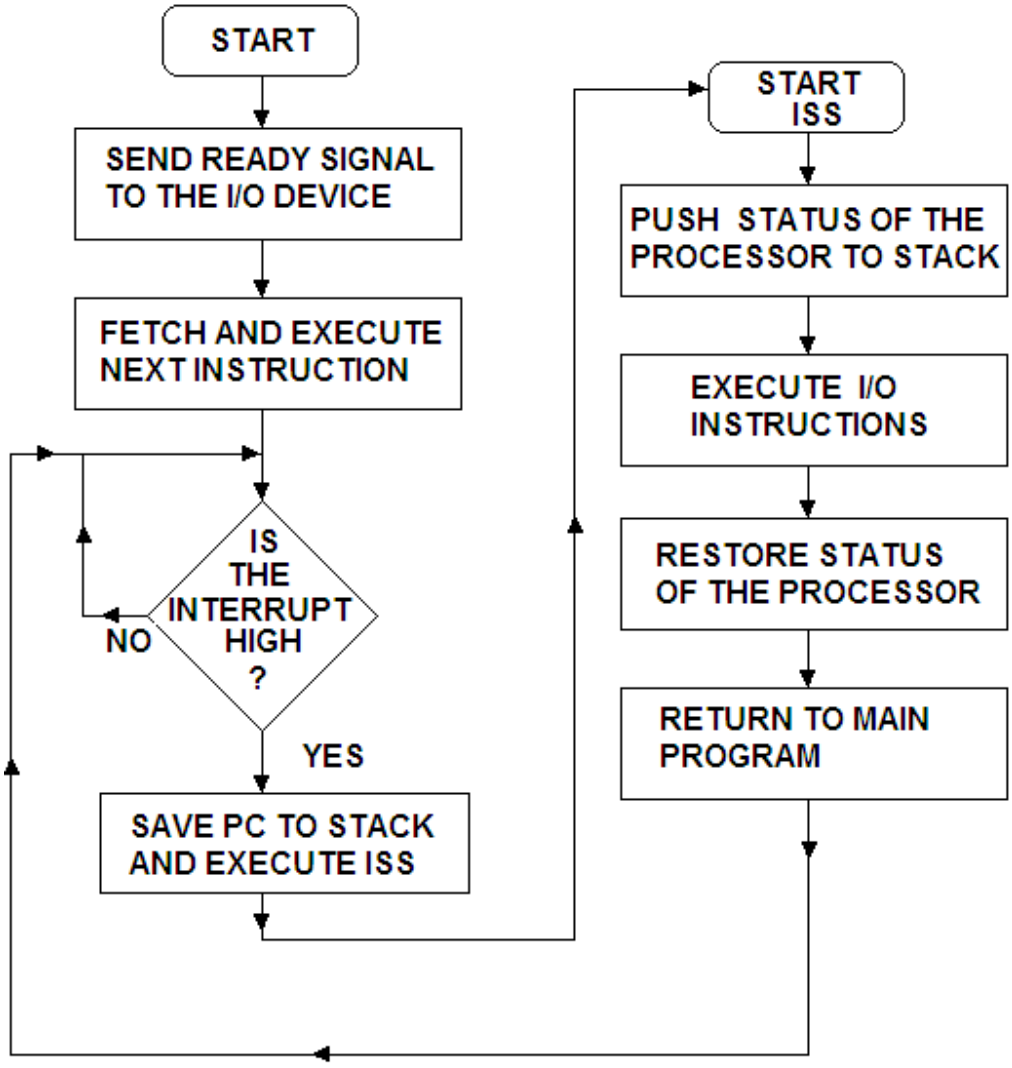

Fig. 7.9

As already discussed, several input/output devices may be connected to microprocessor using Interrupt Driven Data Transfer Scheme. Following interrupt request configuration may arise while interfacing the I/O devices to microprocessor.

1. Single Interrupt system
2. Multi Interrupt System

1. Single Interrupt System

When only one interrupt line is available with the microprocessor and several I/O devices are to be connected, then the method is known as Single Interrupt System. Figure 7.10(a) shows the way to connect several devices to one active low input interrupt terminal ($\overline{INTR}$) of the microprocessor. However, to connect the several I/O devices to active high interrupt terminal (*INTR*) is shown in figure 7.10(b). In the active low interrupt line of the microprocessor the devices are connected to $\overline{INTR}$ terminal through different open collector NOT gates; when any of the devices is active it provides a low

signal to $\overline{INTR}$ enabling the interrupt line. Similarly, in the active high interrupt line the I/O devices are connected through an OR gate. When any of the device is high the output of OR gate sends a high signal to interrupt line (INTR).

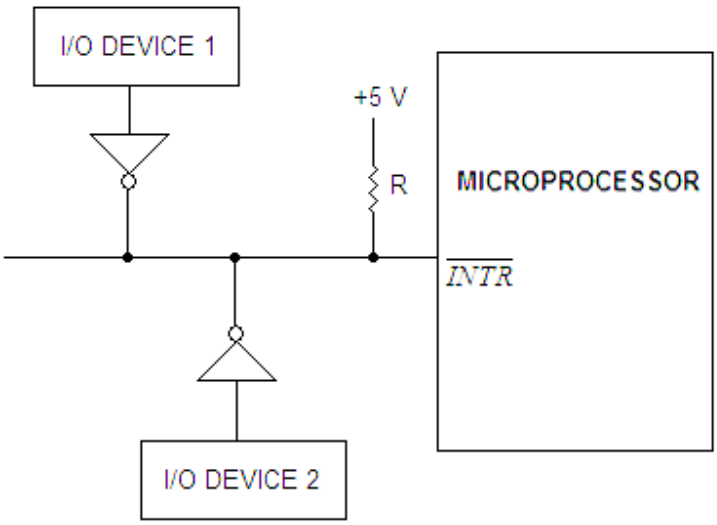

Fig. 7.10(a)

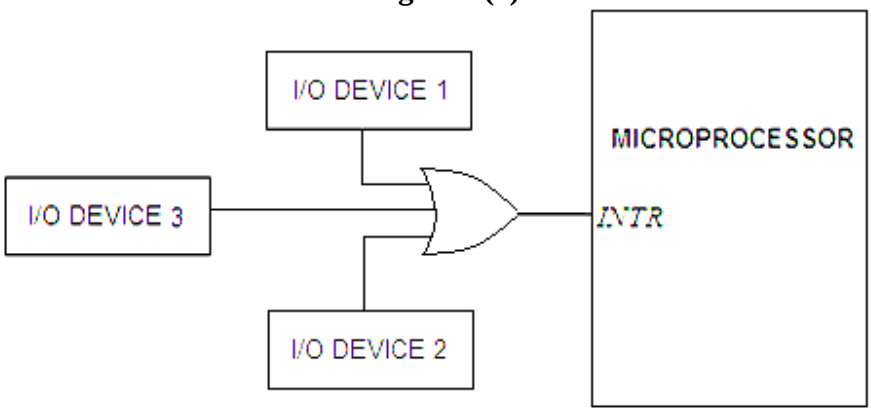

Fig. 7.10(b)

When the interrupt line is active in either of the two methods discussed above, then the microprocessor will not know which device has sent the interrupt signal. Three techniques are commonly used to solve the problem for the microprocessor that is requesting the interrupt and resolving any simultaneous requests by two or more devices. These are:

1. **Polling**: The interrupt signal from each device can be used to set one bit of a register wired as an input port. When an interrupt occurs, the ISS polls this port to see who requested service. A priority is automatically established by the order of polling. This technique is very simple but has the negative of degrading response time.
2. **Daisy Chain**: This technique has been shown in figure 7.11. In this method each I/O device has an Interrupt Enable Input (IEI) and an Interrupt Enable Output (IEO). An interrupt request can be made only if IEI is high. A serial

connection like a chain of all the I/O devices is made. The highest priority I/O device is placed at the first position followed by the lower priority devices in sequence. If any device sends an interrupt signal i.e. low to the interrupt line, then the INTR line of the processor is enabled. The interrupt acknowledge signal (INTA) is enabled in response to low INTR line. In figure 7.11, device 2 is requesting an interrupt causing its IEO to be low. This in turn disables devices 3 and 4. It may be noted that device 1 is still able to request an interrupt because it has a higher priority. The interrupt acknowledge signal can be used to reset IEO of the interrupting device.

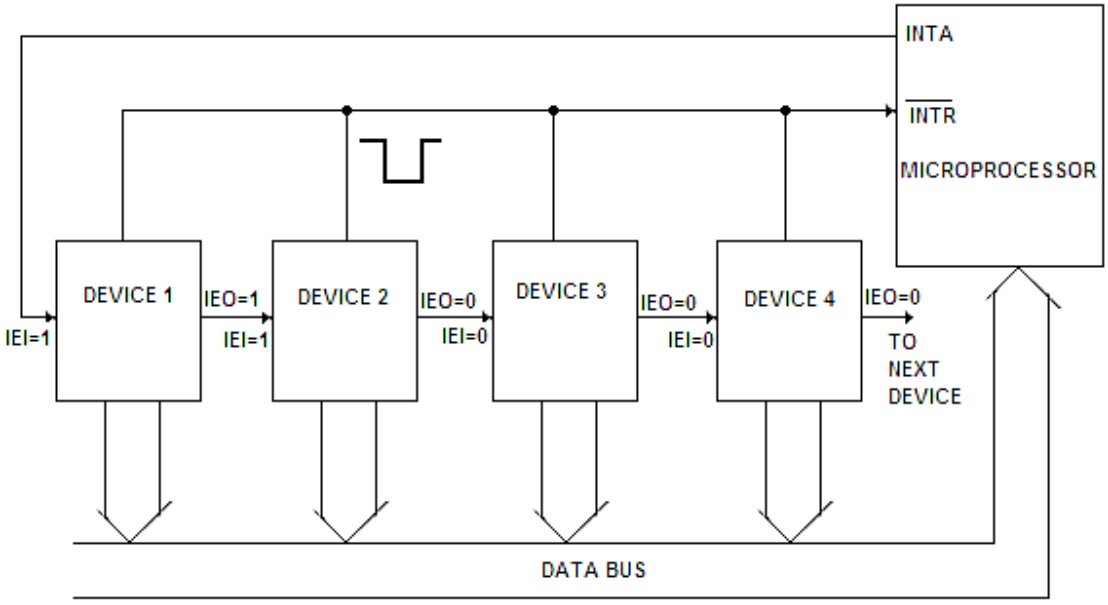

Fig. 7.11

3. **Priority Interrupt Controller (PIC)**: In this method several I/O devices may be connected to a single interrupt line through programmable interrupt controller (IC 8259). Up to 8 input/output devices may be connected to the microprocessor. If more than 8 I/O devices to be connected, more PICs (programmable interrupt controllers) are used in cascade. The details of PIC will be discussed in a later chapter.

2. Multi Interrupt System

When the microprocessor has several interrupt terminals and one I/O device is to be connected to each interrupt terminal, then it is known as multi interrupt system. In this scheme, the number of I/O devices to be connected to the interrupt lines should be equal to or less than the number of interrupt terminals. In this way one device is connected to each level of interrupt. So when a device interrupts the microprocessor, it immediately knows which device has interrupted. Such an interrupt scheme is known as vectored interrupt.

7.2.3 Direct Memory Access (DMA) Data Transfer

In programmed I/O or interrupt driven I/O methods of data transfer between the I/O devices and external memory is via the accumulator. For bulk data transfer from I/O

devices to memory or vice-versa, these two methods discussed above are time consuming and quite uneconomical even though the speed of I/O devices matches with the speed of microprocessor; since the data is first transferred to accumulator and then to concerned device. The Direct Memory Access (DMA) data transfer method is used for bulk data transfer from I/O devices to microprocessor or vice-versa. In this method I/O devices are

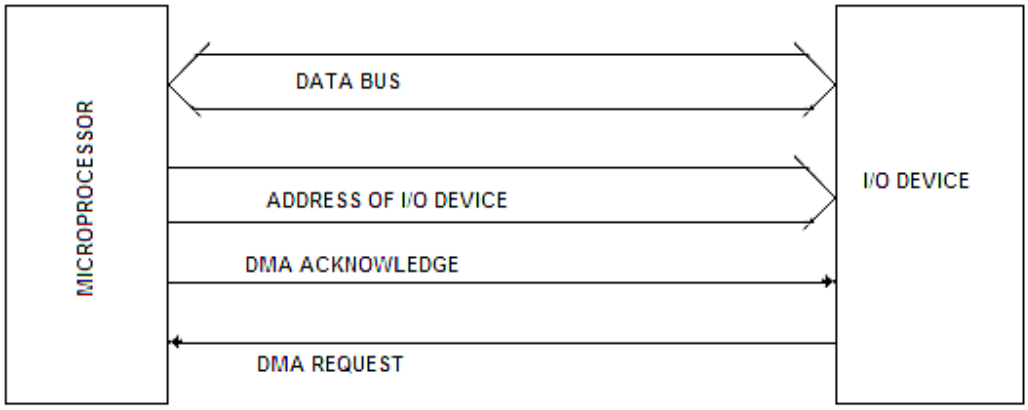

Fig. 7.12

allowed to transfer the data directly to the external memory without being routed through accumulator. For this the microprocessor relinquishes the control over the data bus and address bus, so that these can be used for transfer of data between the devices. For the data transfer using DMA process, a request to the microprocessor by the I/O device is sent and on receipt of such request, the microprocessor relinquishes the address and data buses and informs the I/O devices of the situation by sending Acknowledge signal as shown in figures 7.12 and 7.13. The I/O device withdraws the request when the data transfer between the I/O device and external memory is complete.

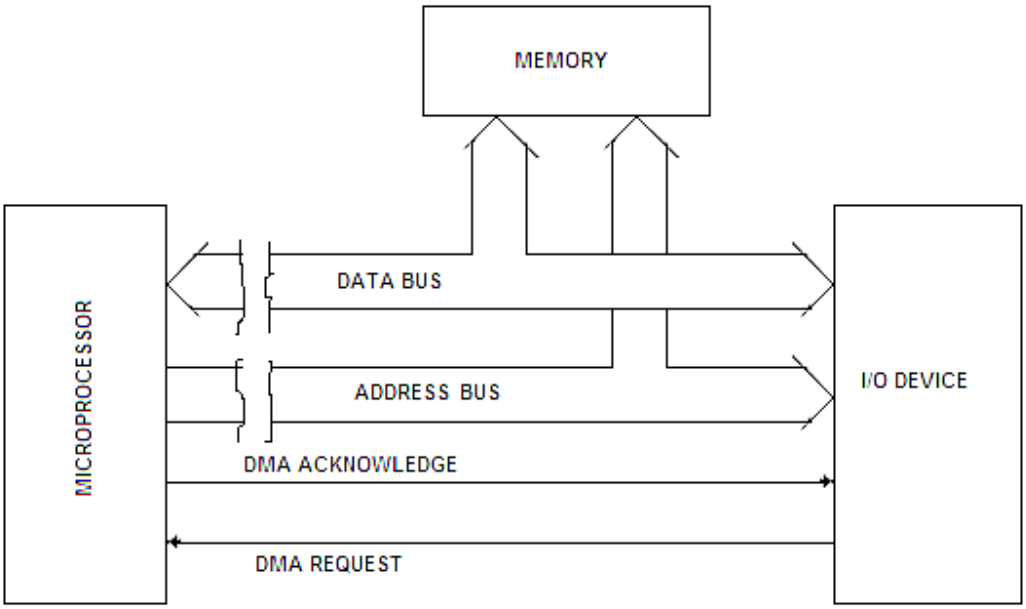

Fig. 7.13

It may be mentioned here that DMA transfer the data of the following types:

- Memory to I/O device
- I/O device to memory
- Memory to memory
- I/O device to I/O device

For transferring the data through DMA, an interfacing chip known as DMA Controller is used with the microprocessor that helps to generate the addresses for the data to be transferred from the I/O devices (Fig. 7.14). The peripheral device sends the request signal (DMARQ) to the DMA controller and the DMA controller in turn passes it to the microprocessor (HOLD signal). On receipt of the DMA request the microprocessor sends an acknowledge signal (HLDA) to the DMA controller. On receipt of this signal (HLDA) the DMA controller sends a DMA acknowledge signal (DMACK) to the I/O device. The DMA controller then takes over the control of the buses of microprocessor and controls the data transfer between RAM and I/O device. When the data transfer is complete, DMA controller returns the control over the buses to the microprocessor by disabling the HOLD and DMACK signals.

7.3 THE 8085 INTERRUPTS

As already discussed, in Interrupt Driven I/O data transfer methods the microprocessor gets interrupted by the I/O device when it is ready to transfer the data. The microprocessor suspends its job after executing the current instruction. It saves the contents of program counter to stack and jumps to the subroutine program. This subroutine program is called Interrupt Service Subroutine (ISS) program. The ISS saves the processor status into stack; and after executing the instruction for the data transfer, it restores the processor status and then returns to main program. The ISS executes the relevant set of instructions stored at a predetermined memory block. The Intel 8085 microprocessor has five hardware interrupt inputs on its chip. Besides these, the microprocessor has eight interrupt instruction in the instruction set. The microprocessor responds to both the hardware and software interrupts. In the following sections the details of both software and hardware interrupts will be discussed.

7.4 SOFTWARE INTERRUPTS

The 8085 microprocessor has eight software interrupts namely, RST 0, RST 1, RST 2, RST 3, RST 4, RST 5, RST 6 and RST 7.

The syntax for these interrupt instructions is given by:

RST n

where *n* varies from 0 to 7.

These instructions are single byte instructions. When an interrupt occurs, a CALL instruction to a predetermined location of the memory is executed. The effect of each restart instruction is shown in table 7. 4.

Table 7.4

Instruction	Effect	Op Code	Binary equivalent	Vector Location
RST 0	CALL 0000 H	C7	1100 0111	0000 H
RST 1	CALL 0008 H	CF	1100 1111	0008 H
RST 2	CALL 0010 H	D7	1101 0111	0010 H
RST 3	CALL 0018 H	DF	1101 1111	0018 H
RST 4	CALL 0020 H	E7	1110 0111	0020 H
RST 5	CALL 0028 H	EF	1110 1111	0028 H
RST 6	CALL 0030 H	F7	1111 0111	0030 H
RST 7	CALL 0038 H	FF	1111 1111	0038 H

These RST instructions are like vectors because they point to specific locations in the memory. The starting address of each instruction is called a **Vector Location**. The vector location for RST 0 is 0000 H and for RST 1 is 0008 H and so on. The vector locations of each instruction are 8 bytes apart. Therefore 8 bytes of instructions can be stored beginning at any vector location.

Figure 7.15 shows the hardware for the implementation of the software interrupt instruction. This circuit is for the implementation of an instruction RST0. In response to the interrupt request signal, the 8085 microprocessor sends the $\overline{INTA}$ (interrupt acknowledge) signal, which is used to enable the buffer. The hex code C7 H of RST 0 will be placed on the data bus.

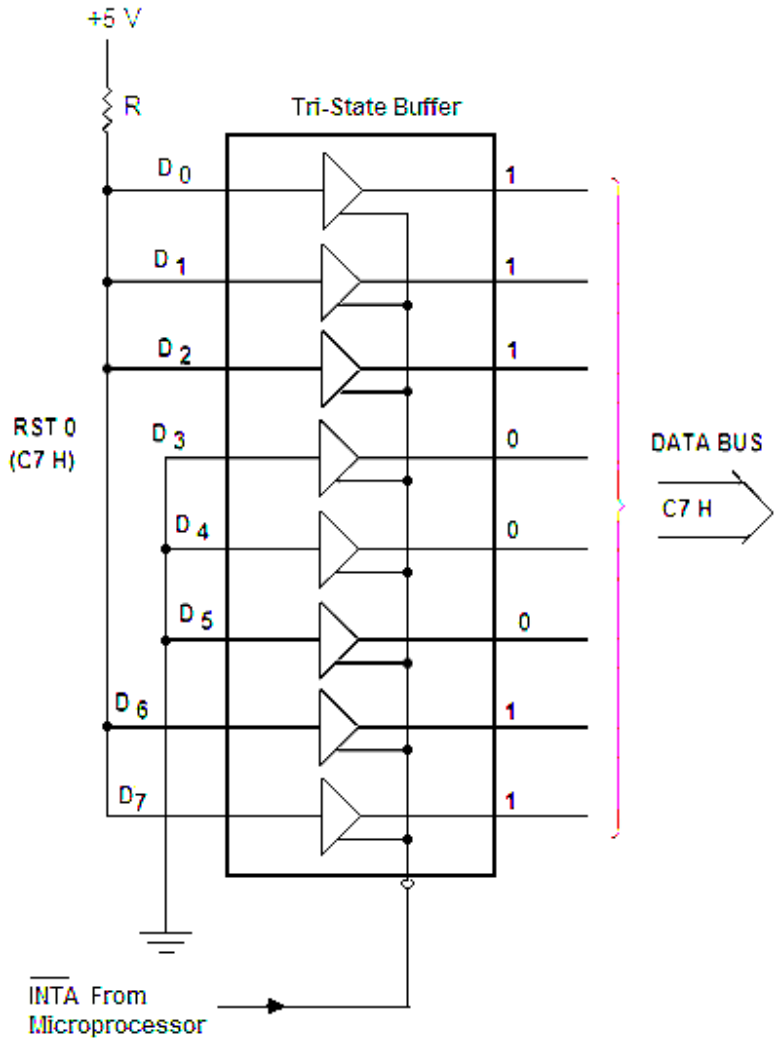

Fig. 7.15

Figure 7.16 illustrates how software interrupt instructions are executed. Suppose in the main program RST2 instruction is given, and when this instruction is executed the contents of the program counter is pushed onto the stack. Then the program counter jumps to the address 0010 H. The subroutine located from 0010 H to 0017 H is executed, with the RET instruction as the last instruction of the subroutine program. So as the RET instruction is executed it returns to the main program.

Similarly, if another restart instruction RST4 is encountered in the main program, then the contents of the program counter are again pushed onto the stack. The program jumps to the subroutine program whose starting address is given by 0020 H. After the execution of this subroutine program it returns to the main program as shown in figure 7.16.

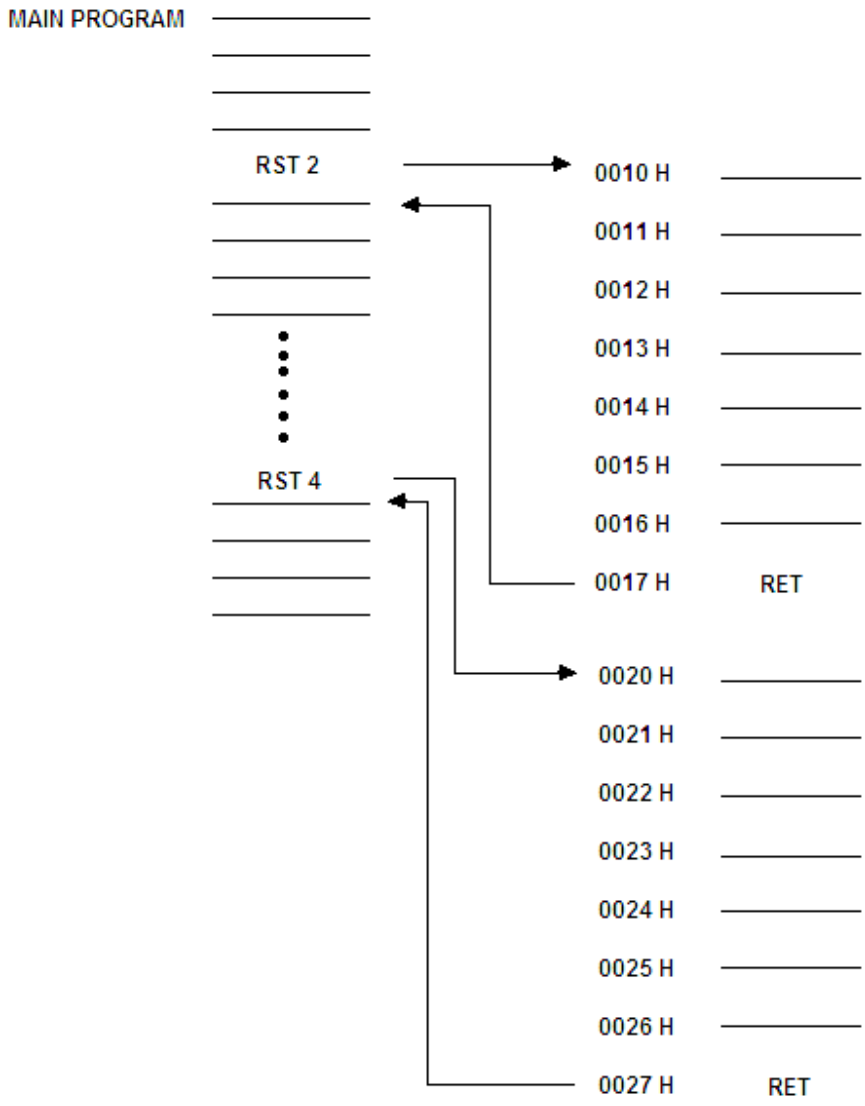

Fig. 7.16

From the above discussion it is clear that the software interrupt instructions are basically special kind of CALL instructions; when any of these instructions is executed it branches to the predetermined address. Notice that all these instructions are of one byte (ref. table 7.4) while the standard CALL instruction is of three bytes. The vector addresses of these 8 software interrupts are 8 bytes apart. So 8 bytes of instructions can be stored in the subroutine program associated with each of these instructions. But generally, the subroutine programs may require more than 8 bytes. For this reason the complete subroutine program are usually not stored in the vector locations, rather the vector locations are used to specify the starting address of the longer subroutine program i.e. in the vector location of these instructions JMP XXXX H may be stored. The XXXX H represents the starting address of the longer subroutine program. The last instruction of the program will be RET, so that after completing the subroutine program it jumps to the main program as shown in figure 7.17.

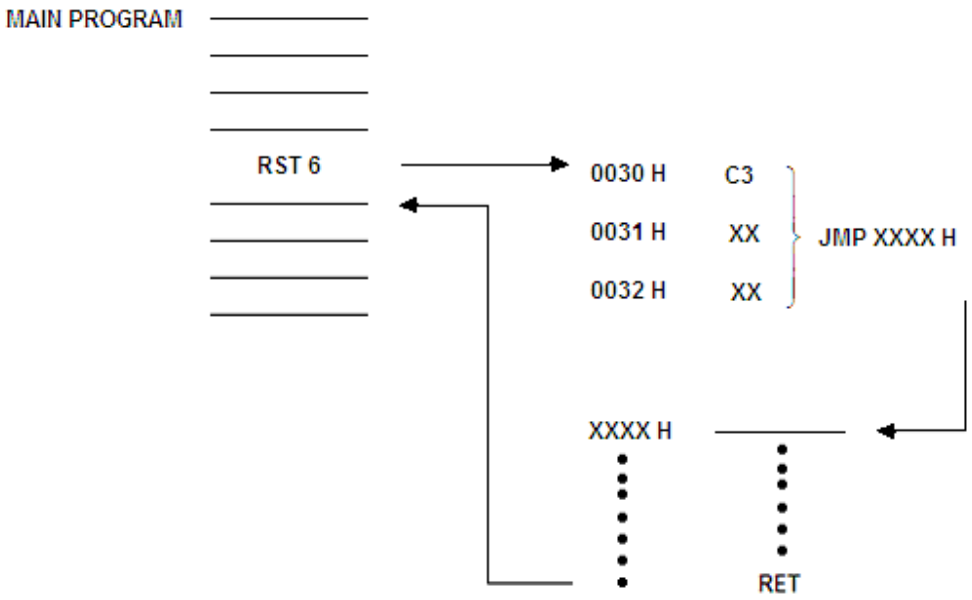

Fig. 7.17

The hardware solution to multi-interrupt problem is carried out by the circuit shown in figure 7.18. The multi-interrupt problem means the possibility of two requests arriving simultaneously. This circuit will accept eight interrupt request and work as per their priority and separate RST instruction for each request is generated. For the generation of all eight RST instructions, a 3-to-8 priority encoder (IC 74LS148) along with a tri-state octal buffer (IC 74LS244) is used as shown in figure 7.18.

The 3-to-8 priority encoder generates a 3 bit binary code corresponding to active input. If two or more inputs are active simultaneously, the highest numbered input will be encoded. The three bits are inverted by the inverted buffer and then applied to an octal buffer (IC 74LS244). The op code corresponding to the input will be generated which is latched on to the data bus if $\overline{INTA}$ signal is active.

The op codes for each RST instruction given in table 7.4 are reproduced below:

Instruction	Op Code	Binary equivalent
RST 0	C7	1100 0111
RST 1	CF	1100 1111
RST 2	D7	1101 0111
RST 3	DF	1101 1111
RST 4	E7	1110 0111
RST 5	EF	1110 1111
RST 6	F7	1111 0111
RST 7	FF	1111 1111

It may be noted from this op code table that D_0 to D_2 and D_6 to D_7 bits of the op codes are same for all the RST instructions (RST 0 to RST 7). The bits D_3 to D_5 are different and are in the sequence of 3 bit binary numbers for the RST 0 to RST 7. In general the code for RST instructions may be written as:

11CCC111

where CCC is

000 for RST 0
001 for RST 1
010 for RST 2
011 for RST 3
100 for RST 4
101 for RST 5
110 for RST 6
111 for RST 7

This sequence permits to use the 3-to-8 priority encoder. It can be understood that a signal say $\overline{INT3}$ is low then A_0 A_1 A_2 will be100 which will be inverted by the inverter buffer as 011 (I_3 I_4 I_5). Since the other lines I_0, I_1, I_2, I_6, I_7 are all high, the octal buffer will provide the op code DF H (op code for RST 3) on the 8085 data bus as soon as the interrupt acknowledge signal ($\overline{INTA}$) is made low in response to the interrupt request signal. Similarly by activating other inputs of the priority encoder, the vector CALL instructions can be generated on the 8085 data bus.

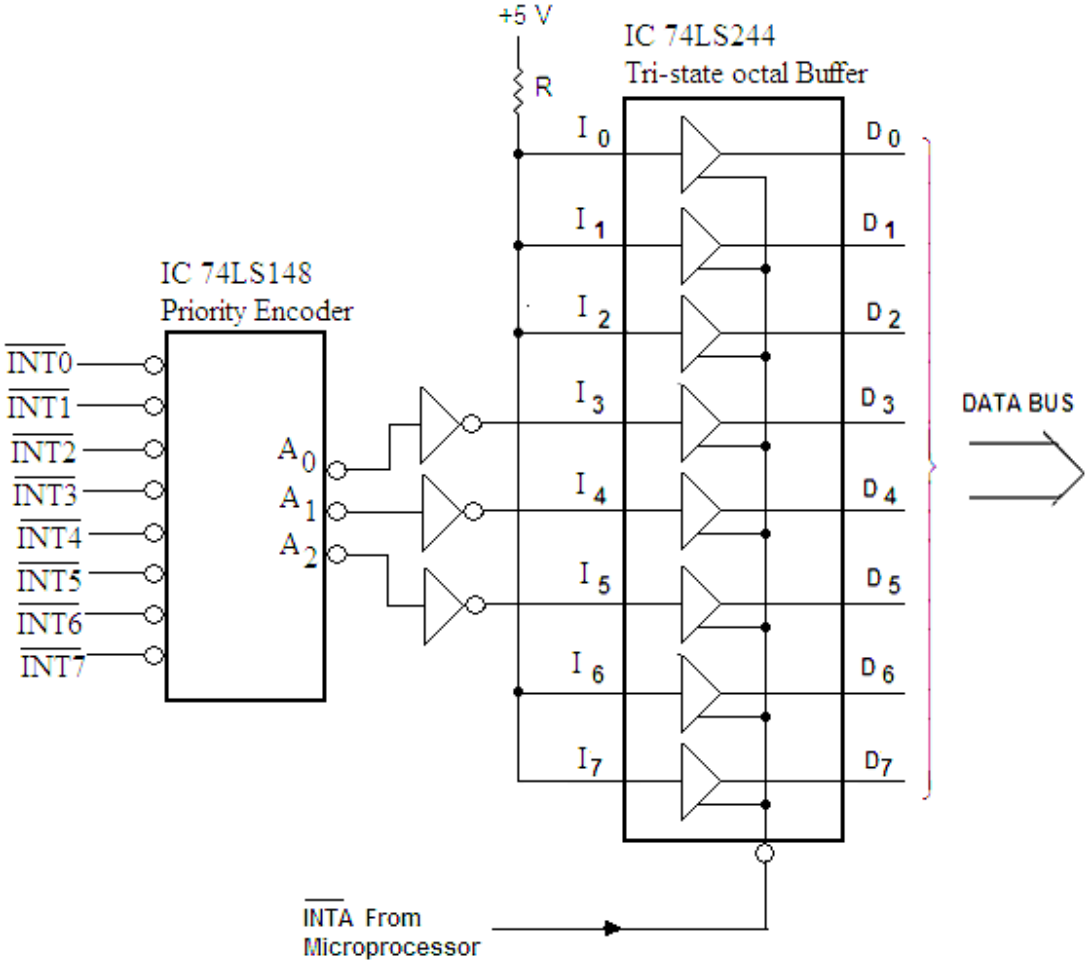

Fig. 7.18

7.5 HARDWARE INTERRUPTS

In addition of software interrupts discussed above the 8085 has five hardware interrupts also. For this, five hardware input pins are provided in the microprocessor. The hardware interrupts are initiated by an external device, by placing an appropriate signal at the interrupt pin of the microprocessor. The five interrupts RST 5.5, RST 6.5, RST 7.5, TRAP and INTR are shown in table 7.5. Out of these interrupts RST 5.5, RST 6.5, RST 7.5 and TRAP are vector interrupts and INTR is the non-vectored interrupt. In vector interrupts the microprocessor automatically sends the specific address to program counter in response to an interrupt request signal. However, in non-vectored interrupt, the interrupt device has to give the address of the interrupt service subroutine.

Table 7.5

Interrupt	Priority	Vector Location
TRAP	1	0024 H
RST 7.5	2	003C H
RST 6.5	3	0034 H
RST 5.5	4	002C H
INTR	5	-----

It may be noted from the table that TRAP has the highest priority, RST 7.5 next highest and so on. If two or more hardware interrupts are served at the same time then the microprocessor executes them in order of their priority level; i.e. TRAP is served first, then RST 7.5 and so on. When highest priority interrupt is executed, the lower priority interrupts remain pending rather they are known as pending interrupts.

The RST 7.5, RST 6.5 and RST 5.5 are the maskable interrupts and TRAP is non-maskable interrupt. The maskable means the prevention of any interrupt. Some times it may be required to prevent one or more interrupts when a certain task is being carried out by the microprocessor; for this the masking of these interrupts is done. The masking of any interrupt is carried out by an instruction known as SIM (Set Interrupt Mask). The SIM is one byte instruction. To find the status of the interrupts i.e. to know which interrupt is masked or which interrupt is pending, another instruction known as RIM (Read Interrupt Mask) is used. These two instructions RIM and SIM will be discussed in section 7.7.

7.6 INTERRUPT CONTROL CIRCUIT

Figure 7.19 shows the interrupt control circuit with 8085 microprocessor. The TRAP is non-maskable interrupt i.e. it is neither be affected by any flag nor can be masked. It is used to handle very important functions. Since it is a highest priority interrupt, so it is used to take care of parity errors, power failure and other events that needs immediate attention. In the case of power failure, it may execute a routine to transfer the contents of the main memory to the back up memory (if any); and also for parity errors, the data may be corrected before carrying on. It is edge and level trigger which means the input has to go high and stays high. The rising edge and level triggered TRAP signal triggers the D flip-flop. The logic '1' at the output of D flip-flop and logic '1' of the TRAP input enable the AND gate to trigger the TRAP interrupt i.e. it calls the vector location 0024 H as shown in figure 7.19. Once the TRAP is recognized, further inputs at the TRAP will not be considered unless the interrupt is reset. The TRAP interrupt will be reset if the $\overline{RESET}$ signal is active (low) or internal TRAP

Acknowledge signal is high. After the 8085 microprocessor recognizes a TRAP interrupt, it will send a high TRAP acknowledge signal which will reset the D flip-flop.

RST 7.5 is a maskable interrupt which can be enabled or disabled by using SIM instruction. This is an edge triggered interrupt. When a leading edge signal appears at the RST 7.5 pin of 8085 microprocessor, D flip-flop 2 will be set (ref. figure 7.19). The output of this flip-flop is labeled as I 7.5 which is known as pending interrupt. This is one input of AND gate 2. The AND gate 2 will not be enabled until other two inputs of the gates are high. The RST flip-flop will be reset either by having a high R 7.5 bit or by having a high RST Acknowledge signal. The interrupt Acknowledge signal resets it for future RST 7.5 interrupt.

RST 6.5 and RST 5.5 are also maskable interrupts which may be enabled or disabled using SIM instruction. Both are level triggered interrupts. When a high signal (constant voltage of +5 V) appears at RST 6.5 pin of the microprocessor, it will enable one pin of AND gate 3. Till RST 6.5 interrupt pin is high and other two pins of AND gate 3 are low, this interrupt is known as pending interrupt (I 6.5). Similarly, when a high signal appears on RST 5.5 pin of the microprocessor, it will enable one terminal of AND gate 4. This interrupt will be pending interrupt (I 5.5) till RST 5.5 pin is high and other two inputs of AND gate 4 are low.

It may be noted from the figure 7.19 that one input each of the AND gates 2, 3 and 4 is connected to IE signal (called interrupt enable flag). The second pin of these gates will be enabled if IE signal is high. The IE signal may be made to high by enabling

the EI (Enable Interrupt) signal, which may be enabled by a software instruction **EI**. This instruction will be discussed in the succeeding section.

The mask bits M 7.5, M 6.5 and M 5.5 for the interrupts may be set using the SIM instruction. To mask an interrupt, the corresponding mask bit has to be set. So to enable a pending interrupt, the corresponding mask bit should be made low (by SIM instruction) and interrupt enable flag should made high (by EI instruction).

All the maskable interrupts may be disabled by either sending a low signal to $\overline{RESETIN}$ terminal or a high signal to 'Any Interrupt Acknowledge' terminal. The DI signal may also disable all the maskable interrupts. The DI (Disable Interrupts) is a software instruction.

All these hardware interrupts discussed above, once enabled will execute the corresponding hardware CALL instruction specified by their vector locations, as per their priority levels.

INTR is a lowest priority, maskable and level triggered interrupt. It uses handshaking. A high signal to INTR pin of the microprocessor will cause the current instruction to complete and will put the contents of the program counter into stack. The microprocessor will then generate a low $\overline{INTA}$ (interrupt acknowledge) signal. This signal is then used to enable a tristate buffer for the execution of hardware CALL instruction. It will execute the service subroutine program corresponding to any of the 8 software interrupts (RST 0 through RST 7).

7.7 INTERRUPT INSTRUCTIONS

Once the microprocessor recognizes any of the interrupts, it immediately disables all the interrupts except TRAP. This is done just to ensure that no further interrupts are recognized while the interrupt service subroutine (ISS) is being executed. Once the ISS is complete the program is required to enable the interrupts again. For this one byte instruction EI is introduced just before the RET instruction of ISS.

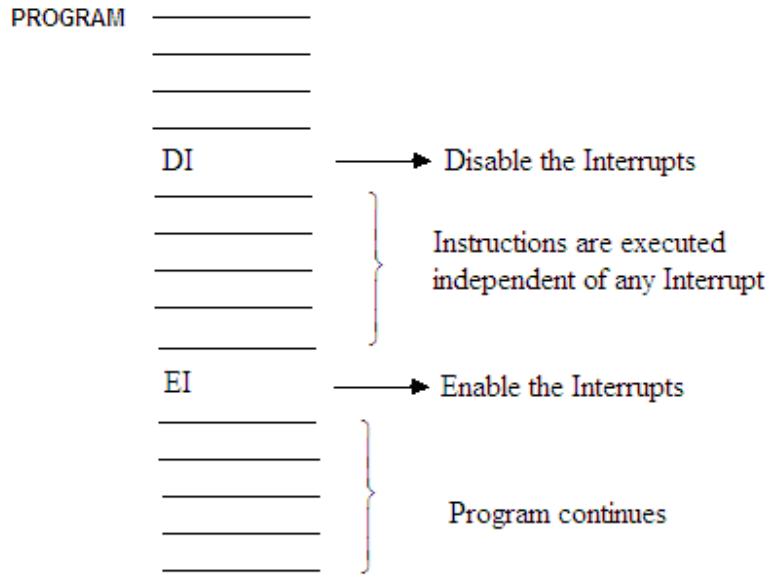

Fig. 7.20

Some portion of the main program may, sometimes be executed without being enabled the interrupt signals. For this the interrupts are to be disabled. The interrupts may be disabled by one byte instruction DI (Disable Interrupts). Later the interrupts may be enabled as shown in figure 7.20.

EI and DI Instructions

The instruction

EI

stands for Enable Interrupt. When this instruction is executed, it produces a high EI signal (fig. 7.19), which sets the flip-flop 3 and produces a high signal to interrupt enable flag (IE). This way EI instruction enables all the interrupts except TRAP.

The instruction

DI

stands for Disable Interrupts. When this instruction is executed, it produces a high DI bit of flip-flop 3 (fig. 7.19). This resets the flip-flop and results a low IE (interrupt enable flag) signal. The low IE signal disables all the interrupts except TRAP.

SIM and RIM Instructions

It is often required to selectively enable a few interrupts and disable others. The selectively enabling or disabling the interrupts can be done by an instruction

SIM

It stands for set interrupt masks. This instruction is used by loading the accumulator as shown in figure 7.21. The accumulator is loaded by *MVI A, data* (data bits are as per the requirements) instruction. The SIM instruction is then executed.

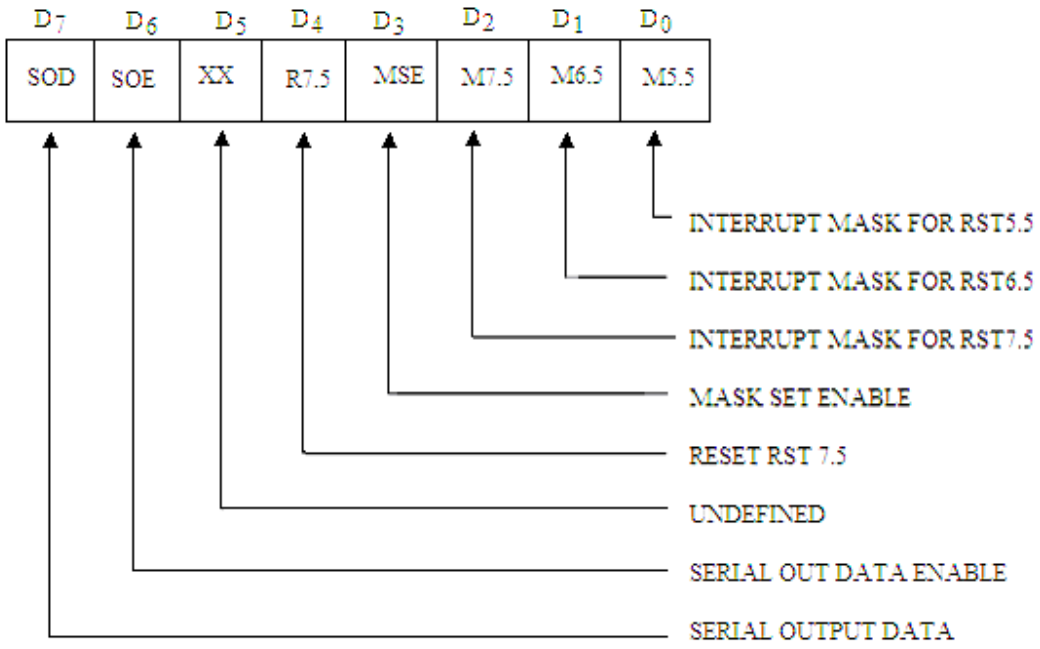

Fig. 7.21

The meaning of the different mask bits are given below:

The bits D_0 to D_2 are the mask bits (M 5.5 to M 7.5). A high to either of these bits represents that the particular interrupt is masked and a low, however, to either of these bits represents the enabling of that particular interrupt.

The bit D_3 is known as MSE (Mask Set Enable). When this bit is low, the mask bits D_0 to D_2 are ignored. A high to this bit indicates that the bits D_0 to D_2 are valid as described above.

The bit D_4 when high resets the flip-flop 2 (figure 7.19), in order to override RST 7.5 without servicing it.

D_5 is undefined bit.

The bits D_6 to D_7 are used for the serial transfer of data through the SOD line. The working of these pins will be described later.

Let us take an example to illustrate the function of SIM instruction. For example we have

```
MVI A, 0C H
SIM
```

instructions in an assembly language program for 8085 microprocessor. When first instruction MVI A, 0C H is executed it will have the data (as shown in figure 7.22) for

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0
0	0	0	0	1	1	0	0

Fig.7.22

the execution of SIM. The SIM instruction after its execution will enable MSE signal (as D_3 bit is high). RST 7.5 interrupt is masked (bit D_2 is 1) and RST 5.5 and RST 6.5 interrupts are unmasked (enabled) as bits D_0 and D_1 are both 0. It will prevent the RST 7.5 interrupt from arriving at the final output.

The another interrupt instruction is

RIM

It stands for Read Interrupt Mask. This instruction will give the present status of the interrupt. This instruction loads the accumulator with 8 bit data whose details are given in figure 7.23.

The meanings of the different bits for RIM are given below:

The bits D_0 to D_2 represent the masking of RST 5.5, RST 6.5 and RST 7.5 interrupts. A high to either of these bits represents that the particular interrupt is enabled; and a low to either of these bits represents that the particular interrupt is disabled.

The bit D_3 is known as interrupt enable flag (IE). When this bit is low, all the interrupts except TRAP are disabled and a high to this bit mask the bits D_0 to D_2 are ignored. A high to this bit indicates that the bits D_0 to D_2 are valid as described above.

The bits D_4 to D_6 represent the pending interrupts. A high to either of these bits represents that particular interrupt is pending; and a low to either of these bits represents that particular interrupt is not pending.

The bit D_7 is a serial input data and used for the serial input data through SID line. The working of this bit will be discussed later.

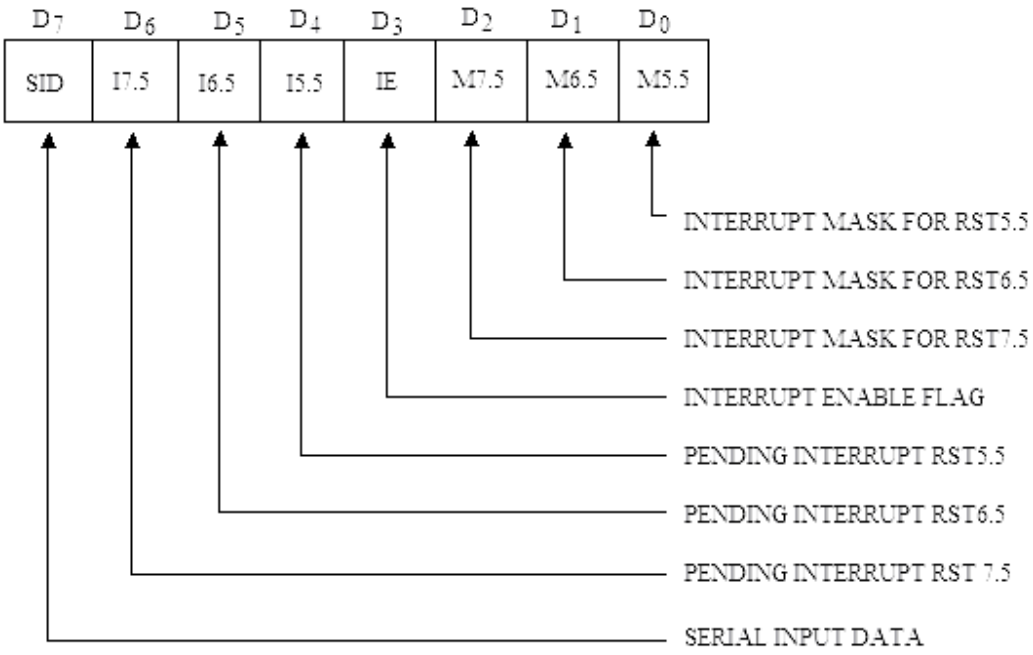

Fig. 7.23

Let us take an example to illustrate the function of RIM instruction. Suppose after the execution of RIM instruction, the accumulator contains 2A H as the data as shown in figure 7.24. The high to I 6.5, IE and M 6.5 bits indicate that RST 6.5 is a pending interrupt, the interrupt system is enabled and the RST 6.5 is currently masked.

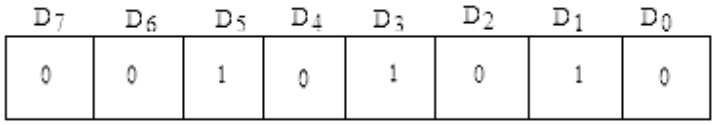

Fig. 7.24

Example 7.1. *Write an assembly language program for 8085 microprocessor to enable RST 5.5 interrupt and disable RST 6.5 and RST 7.5 interrupts.*

Solution. To enable RST 5.5, the bit D_0 (M 5.5) for the accumulator should be 0 (unmask); and for disabling RST 6.5 and RST 7.5, the bits D_1 and D_2 (M 6.5 and M 7.5) should be masked (1). Also MSE should be 1 (enable). The program will, therefore, be as given below:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
SOD	SOE	XX	R 7.5	MSE	M 7.5	M 6.5	M 5.5	
0	0	0	0	1	1	1	0	
								=0E H

```
EI
MVI A, 0E H
SIM
```

Example 7.2. *Write an assembly language program for 8085 microprocessor to enable all the interrupts.*

Solution. The program for this case will be as given below. The bits D_0 to D_2 should be unmask and MSE should be enabled.

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
SOD	SOE	XX	R 7.5	MSE	M 7.5	M 6.5	M 5.5	
0	0	0	0	1	0	0	0	
								=08 H

```
EI
MVI A, 08 H
SIM
```

Example 7.3. *Write an assembly language program for 8085 microprocessor to enable RST 5.5 and RST 6.5 interrupt and reset 7.5 interrupt.*

Solution. The program for this case will be as given below. The bits D_0 and D_1should be unmasked and MSE should be enabled. For resetting of RST 7.5, the bit D_4 (R 7.5) should also be 1.

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
SOD	SOE	XX	R 7.5	MSE	M 7.5	M 6.5	M 5.5	
0	0	0	1	1	1	0	0	
								=1C H

```
EI
MVI A, 1C H
SIM
```

Example 7.4. *Write an assembly language program for 8085 microprocessor to check if RST 5.5 is pending. If it is pending, enable it without affecting any other interrupt else return to main program..*

Solution. The program for this problem is given below. The RIM instruction will check if RST 5.5 is a pending interrupt. For this bit pattern of the accumulator will be checked. If bit D_4 is 1, the RST 5.5 is pending interrupt otherwise not.

For RIM

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0
SID	I 7.5	I 6.5	I 5.5	IE	M 7.5	M 6.5	M 5.5

For SIM

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0
SOD	SOE	XX	R 7.5	MSE	M 7.5	M 6.5	M 5.5

```

```

```
SIM
JMP        ISS        ; Jump to service subroutine for RS
                        T5.5.
```

7.8 SERIAL INPUT AND OUTPUT DATA TRANSFER

As already discussed in the architecture of 8085, two pins (Pin Nos. 4 and 5) are provided for SOD (Serial Out Data) and SID (Serial In Data) lines. These lines are used for serial data transfer. The data transfer to or from the SID or SOD lines is possible using the Instructions RIM (Read Interrupt Mask) and SIM (Set Interrupt Mask).

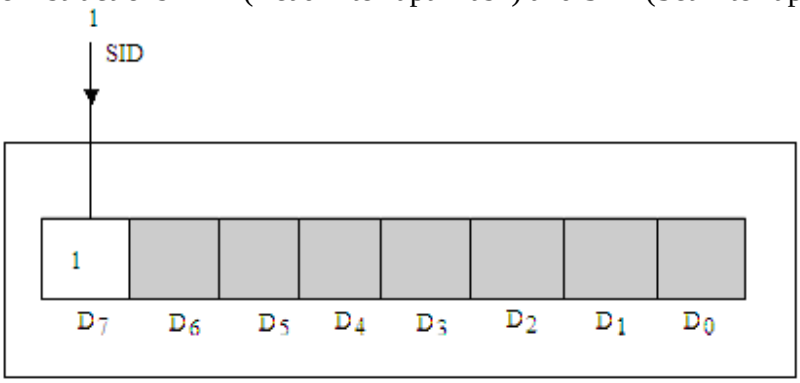

Fig. 7.25

The data on the SID line (Pin 5 of 8085) is loaded into accumulator at bit D_7 whenever a RIM instruction is executed. In other words a RIM instruction may be executed each time a new bit arrives at the SID input. For example, let a bit '1' arrives at the SID input. RIM instruction is now executed. After the execution of RIM instruction D_7 bit of the accumulator will be 1 as shown in figure 7.25.

Further to input 8 bit data serially through SID line, RIM instruction is executed 8 times and each time D_7 bit may be isolated and saved for the conversion of serial data into parallel data.

The SIM instruction sends the D_7 bit of the accumulator to the SOD line of 8085. For this transfer, D_6 bit (SOE) of the accumulator must be high as shown in figure 7.26.

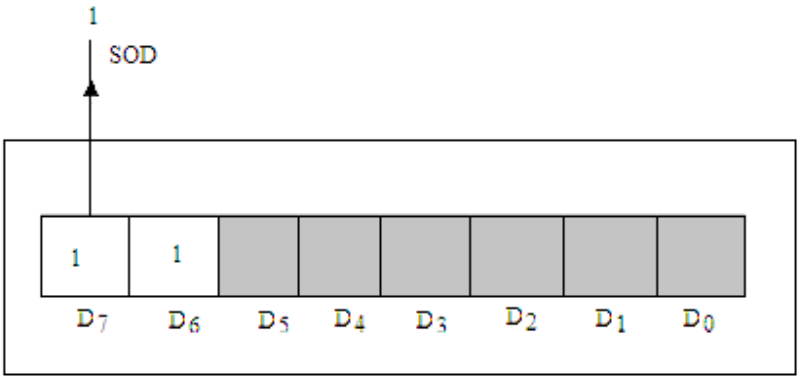

Fig. 7.26

Suppose we wish to send a '0' bit to the SOD line, this can be done as:

```
MVI A, 40 H
SIM
```

Similarly, to send a '1' bit to the SOD line, we use

```
        MVI A, C0 H
        SIM
```

The rotate or other instructions may used to convert 8 bit parallel data to serial data stream at the SOD output.

It may be noted from the above discussion that bit D_7 is used for SID line and this bit has nothing to do with the interrupt system. Similarly, bits D_6 and D_7 are used for SOD line and these bits have nothing to do with the interrupt system. So no new instructions are to be used for the serial transfer of data, i.e. interrupt instructions RIM and SIM may be used for this purpose also.

Example 7.5. *Consider a switch is connected to SID line and an LED to SOD line of 8085. It is required to input the SID line via switch and output the switch status to the LED. In other words when the switch is ON or OFF the LED should glow or not glow. Write an assembly language program to accomplish this.*

Solution. Program to accomplish the required work of the problem is given as:

```
Label   Mnemonics   Operand    Comments
START   RIM                    ; Read Interrupt mask, Bit D7 of A is SID.
        ORI         40 H       ; Enable SOE for SIM.
        SIM                    ; Output to LED.
        JMP         START      ; Jump to START.
```

Example 7.6. *Write an assembly language program to generate a symmetrical square wave of known frequency at the SOD line of 8085 microprocessor.*

Solution. To generate a square wave of certain frequency, SOD line should remain high for certain time and then low for the same amount of time. This is done by using the program given below. The time for the delay should be as per the frequency of the wave to be generated.

MAIN PROGRAM:

```
Label   Mnemonics   Operand    Comments
START   MVI  A,      C0 H      ; Enable SOE and SOD (D6 and D7) and disables all interrupts for SIM.
        SIM                    ; Sends high signal to SOD line.
        CALL        DELAY      ; Delay is introduced for SOD to remains high for certain time.
        MVI  A,     40 H       ; SOD is made low; and SOE and all interrupts are disabled for SIM.
        SIM                    ; Sends low signal to SOD line.
        CALL        DELAY      ; Again delay is introduced for SOD to remain low for certain time.
        JUMP        START      ; Repeats the process.
```

SUBROUTINE PROGRAM:

```
Label   Mnemonics   Operand    Comments
DELAY   LXI  D,     XXX H      ; Loads DE register pair with a 16-bit number.
LOOP    DCX  D                 ; Decrements DE register pair by 1.
```

```
        MOV  A,     E       ; Moves the contents of E register to
                            accumulator.
        ORA  D              ; ORing of the contents of D and E
                            registers are performed to set the
                            zero flag.
        JNZ  LOOP           ; If result is not zero than jump to
                            loop.
        RET                 ; Go back to main program.
```

The 16-bit number XXX H loaded to DE register pair is as per the delay introduced in the program (discussed in chapter 4).

Example 7.7. *Write an assembly language program to input an 8 bit data serially through SID line of 8085 microprocessor. Convert it to 8 bit parallel data and store this data to 2500 H memory location.*

Solution. The program is given as:

Label	**Mnemonics**	**Operand**	**Comments**
	MVI B,	00 H	; Clears Register B.
	MVI C,	08 H	; Preset counter to 8.
LOOP	RIM		; Get the bit through SID line.
	ANI	80 H	; Isolate the bit received through SID line.
	ORA B		; Convert to parallel word.
	RRC		; Rotate right.
	MOV B,	A	; Save the accumulator contents to B register.
	DCR C		; Decrement the contents of C register.
	JNZ	LOOP	; Go to LOOP if not zero.
	RLC		; Rotate left.
	STA	2500 H	; Store the parallel data to 2500 H memory location.
	HLT		

Example 7.8. *An 8 bit data (say 32 H) is to be outputted serially through SOD line of 8085. An LED connected to SOD line, should glow or not glow each time a bit (1 or 0) is outputted through SOD line. A delay of 1 sec is to be introduced between each transfer of a bit. Write an assembly language program to implement this.*

Solution. The program to output 8 bit data serially through SOD line is given below, which is self explanatory.

MAIN PROGRAM

Label	**Mnemonics**	**Operand**	**Comments**
	MVI A,	00 H	; Loads the data 32 H to accumulator.
	MVI C,	08 H	; Preset counter to 8.
LOOP	RRC		; Rotate LSB to MSB.

```
        MOV  B,     A       ; Save the accumulator contents to B
                            register.
        ANI         80 H    ; Isolate SOD bit.
        ORI         40 H    ; Enable SOE bit for SIM.
        SIM                 ; Sends the bit through SOD line.
        MOV  A,     B       ; Save the present contents to
                            accumulator.
        CALL        DELAY   ; Call the delay for 1 sec.
        DCR  C              ; Decrement the contents of C
                            register.
        JNZ         LOOP    ; Go to LOOP if not zero.
        HLT
```

The delay subroutine program for 1 sec delay may be written as discussed in chapter 4.

SUBROUTINE PROGRAM:

```
Label   Mnemonics   Operand     Comments
DELAY   LXI  D,     F424 H  ; Loads DE register pair with a 16-
                            bit number F424 H.
LOOP    DCX  D              ; Decrements DE register pair by 1.
        MOV  A,     E       ; Moves the contents of E register to
                            accumulator.
        ORA  D              ; ORing of the contents of D and E
                            registers are performed to set the
                            zero flag.
        JNZ         LOOP    ; If result is not zero than jump to
                            loop.
        RET                 ; Go back to main program.
```

Example 7.9. *Write an assembly language program that is interrupted by applying a rising pulse at RST7.5 terminal manually. The program copies 256 bytes of data stored at memory locations starting at 3000 H to memory locations starting at 4000 H. The interrupt signal should, however, be able to introduce a delay of 1 sec. After the delay it should then move to main program. The main program for transferring the data is in a loop that repeats the same task again and again.*

Solution. Here is the program that implements the given task.

MAIN PROGRAM

```
Label   Mnemonics   Operand     Comments
        EI                  ; Enable interrupts
        MVI  A,     08 H    ; Enable RST7.5, RST6.5 and
                            RST5.5.
        SIM
LOOP    LXI  H,     3000 H  ; Load the H-L pair with the starting
                            source address.
        LXI  D,     4000 H  ; Load the D-E pair with the starting
                            address of destination address.
```

```
        MVI  B,     FF H      ; load the B-reg. with the bytes of
                                  data.
NXT     MOV  A,     M         ; Load the accumulator with the
                                  contents stored in memory location
                                  addressed by H-L register pair.
        STAX D                ; Store the accumulator contents to
                                  the destination address given by D-
                                  E register pair.
        INX  H                ; Increments the H-L pair for next
                                  number.
        INX  D                ; Increments the D-E pair
        DCR  B                ; Decrement B.
        JNZ         NXT       ; If not zero jump to NXT.
        JMP         LOOP      ; Jump to start.
        HLT
```

When the interrupt signal is enabled, it calls its vector location 003C H.

At the vector location say it is stored that JMP FFBD H i.e. monitor transfers the program to the memory location FFBD H. Now the user has to transfer from FFBD H to a memory location from where service subroutine for RST7.5 is written. The user transfers the program from FFBD H to 2000 H with the instructions JMP 2000 H. The location 2000 H indicates the starting address of interrupt service subroutine. The interrupt service subroutine is given as:

Interrupt Service Subroutine (at the starting address 2000 H)

```
Label   Mnemonics  Operand     Comments
        PUSH  PSW             : Save accumulator and flag contents
                                  in stack.
        PUSH  B               ; Save the contents of B-C register
                                  pair in stack.
        PUSH  D               ; Save the contents of D-E register
                                  pair in stack.
DELAY   LXI  D,     F424 H    ; Loads DE register pair with a 16-
                                  bit number F424 H.
LOOP    DCX  D                ; Decrements DE register pair by 1.
        MOV  A,     E         ; Moves the contents of E register to
                                  accumulator.
        ORA  D                ; ORing of the contents of D and E
                                  registers are performed to set the
                                  zero flag.
        JNZ         LOOP      ; If result is not zero than jump to
                                  loop.
        POP  D                ; Restore the contents of D-E
                                  register pair from the stack.
        POP  B                ; Restore the contents of B-C register
                                  pair from the stack.
```

```
POP  PSW          ; Restore the contents of
                    Accumulator and flag contents
                    form the stack.
EI                ; Enable interrupts
RET               ; Go back to main program.
```

Program written in ISS is the program for delay of one second as already discussed.

PROBLEMS

1. Discuss the memory Mapped I/O operation for the transfer of data from microprocessor to I/O devices and vice-versa.
2. Discuss the I/O Mapped I/O operation for the data transfer from microprocessor to I/O devices and vice-versa.
3. Give the comparison of memory mapped I/O and isolated I/O scheme fro the data transfer from microprocessor to I/O devices and vice-versa.
4. Why the problems arise when the data is transferred from the microprocessor to I/O devices and vice-versa? Mention various data transfer scheme.
5. Discuss programmed I/O data transfer scheme.
6. Describe Interrupt driven I/O data transfer scheme.
7. What do you mean by handshaking? How is it used in asynchronous data transfer between microprocessor and I/O devices?
8. What is DMA? Using block diagram explain how the data is transferred by a DMA controller.
9. Discuss DMA for 8085.
10. What is an interrupt? How data is transferred between the microprocessor and I/O devices.
11. What is the difference between software and hardware interrupts? Discuss software interrupts of 8085.
12. How is the INTR interrupt used in 8085?
13. Differentiate between
    (i) Memory mapped I/O and I/O mapped I/O data transfer schemes.
    (ii) Maskable and Non-maskable Interrupts
    (iii) Hardware and Software interrupts
14. Explain briefly the following:
    (i) DMA data transfer scheme
    (ii) Interrupt driven data transfer scheme
15. What are interrupt terminals available in 8085 microprocessor? How SIM and RIM instructions are used to set and read the interrupts.
16. What are hardware interrupts? What is meant by Vectored interrupts?
17. What are the functions of SID and SOD pins of 8085? How RIM and SIM instructions are used to input a bit through SID line and output a bit through SOD line.
18. Explain RIM and SIM instructions.
19. Discuss EI and DI instructions.
20. Write down the procedure to mask the RST6.5 interrupt.
21. Explain RST *n* interrupt circuit of 8085.
22. Discuss the bit pattern for RIM instruction.

23. Discuss the bit pattern for SIM instruction.
24. Draw and explain the interrupt control circuit for 8085 microprocessor.
25. Mention interrupt instructions of 8085. Discuss any two of them.
26. How will you enable all the interrupts of 805?
27. How will you enable RST5.5 and disable RST6.5 and RST7.5?
28. Write an assembly program of 8085 to generate asymmetrical square wave at the SOD line of 8085.
29. Write an assembly language program to input 256 bytes of data serially through SID line of 8085 microprocessor. Convert the 256 bytes of data received serially to parallel data and store the data to memory locations starting at 2500 H.
30. Here are some instructions

    MVI A, 1D H
    SIM

    After SIM instruction is executed, which interrupts are masked.

    (Ans.: RST 5.5 and RST 7.5 are masked.)
31. Here are some instructions

    MVI A, XX H
    SIM

    What should be the value of XX H in MVI instruction so that RST 5.5 and RST 6.5 are masked and all other don't care bits should be set to zero.

    (Ans.: XX H = 0B H)

8

Programmable Peripheral Interface (PPI) 8255A

The various methods of data transfer from the microprocessor to output devices or vice-versa has already been discussed in the preceding chapter. Special interface circuits, known as peripheral interface circuits are to be used for this purpose. The interfacing devices may be classified into two categories namely general purpose peripherals and special purpose peripherals. Basically the I/O devices to be connected to microprocessors are known as peripherals, these are printers, floppy drives, CRT and Cassette recorder etc. The general purpose peripherals are:

- Programmable Peripheral Interface (PPI)
- Programmable Interval Timer
- Programmable Interrupt Controller
- Programmable DMA Controller
- Programmable Communications Interface.

The special purpose peripherals used for interfacing a microprocessor to a specific type of I/O device are:

- Programmable Keyboard and Display Interface
- Programmable Hard Disk Controller
- Programmable Floppy Disk Controller

The present chapter will confine to the discussion of Programmable Peripheral Interface (PPI) IC 8255 A and its application.

8.1 DETAILS OF PPI IC 8255A

The input/output devices are generally interfaced to the microprocessor through the input/output port as shown in figure 8.1. The input/output port is either non-programmable or programmable. A non-programmable port can either be connected in input mode or output mode, i.e. if both input and output devices are to be connected to the microprocessor two separate non-programmable ports are to be used, one for input device and other for the output device. INTEL 8212 is an 8-bit non-programmable I/O port. Figures 8.2 (a) and (b) show the interfacing of 8212 in input and output mode respectively. However, a programmable I/O port can be programmed to act either as an input port or an output port. The INTEL 8255A is a programmable port device. It is most

versatile Programmable Peripheral Interface which may be connected to almost any

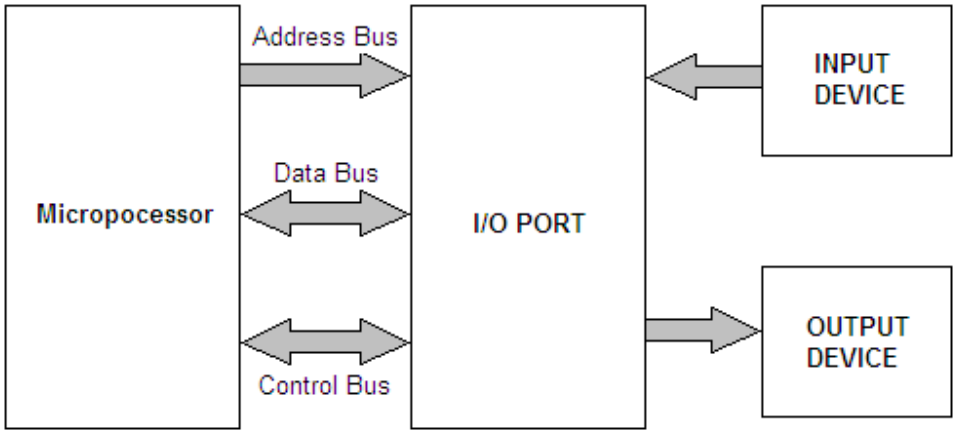

Fig. 8.1

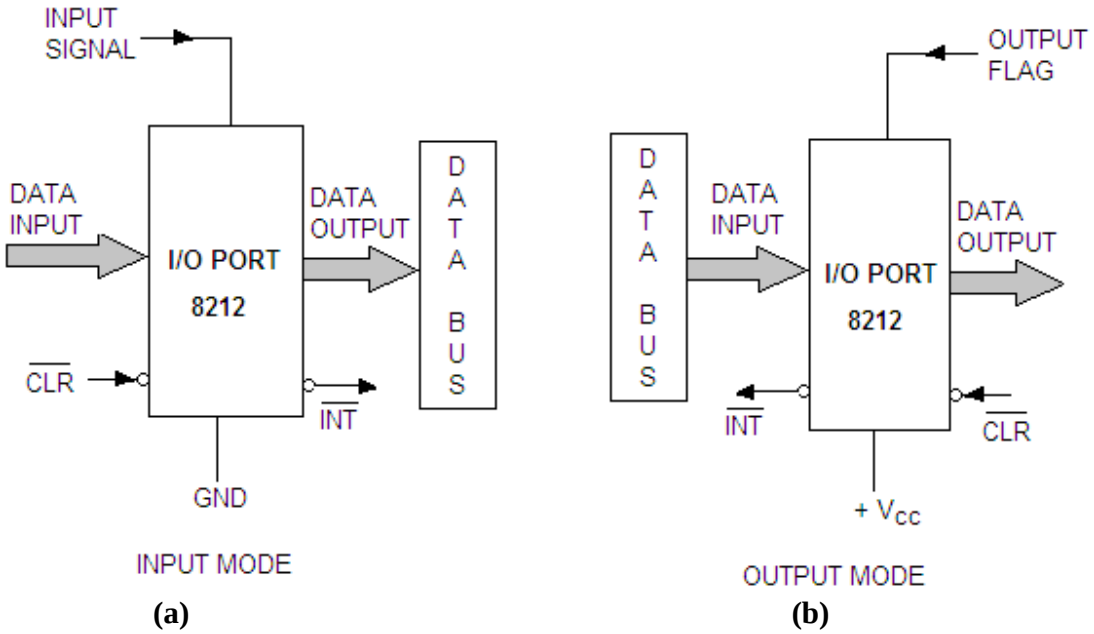

Fig. 8.2

microprocessor. This IC is widely used and can be programmed to transfer the data to the input/output devices. It is a 40 pin dual in line IC package, whose pin configuration and block diagram are shown in figures 8.3 and 8.4 respectively.

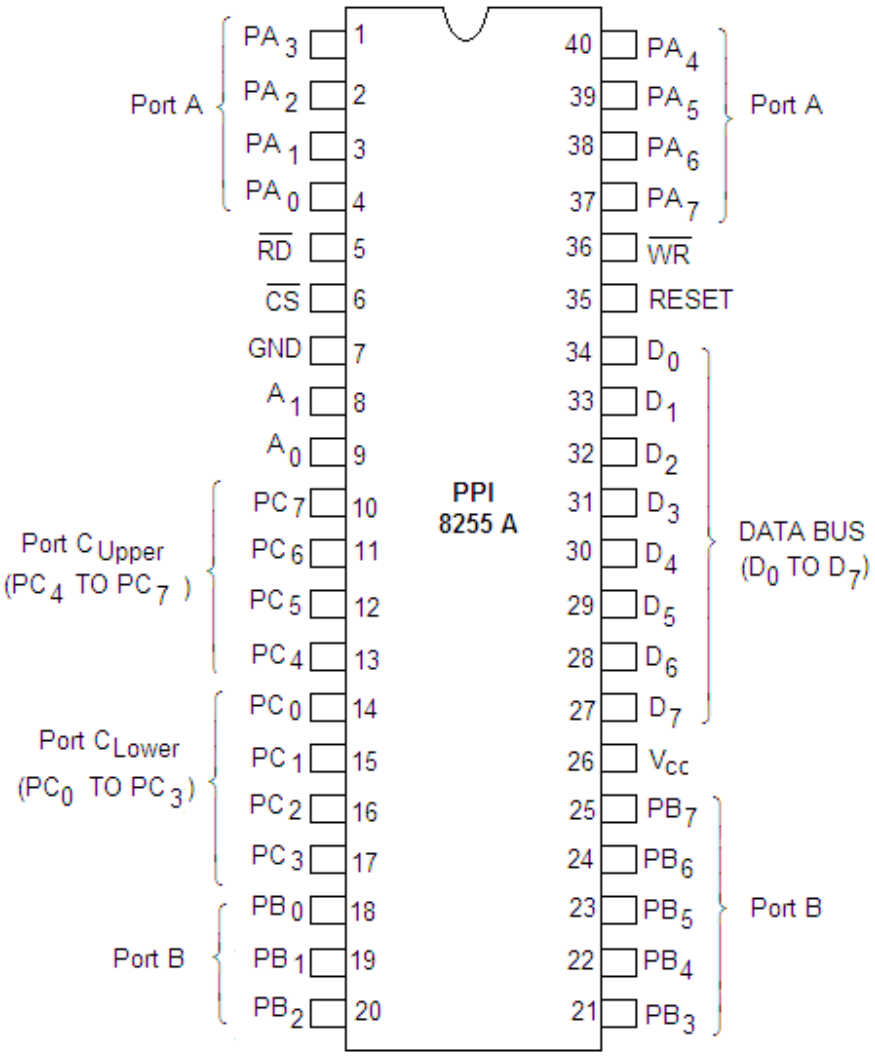

Fig. 8.3

The IC 8255 A has three 8-bit ports:

Port-A
Port-B
and Port-C

The port-C can be used into two 4-bit ports represented as Port C_{Upper} and Port C_{Lower}.

Port-A (PA_7-PA_0) and Port-C_{Upper} (PC_7-PC_4) together form Group A, whereas Port-B (PB_7-PB_0) and Port-C_{Lower} (PC_3-PC_0) form Group B as shown in figure 8.5.

After deciding the configuration of 3 ports (which port is to be used as input port and which port is to be used as output port), a control word of the command has to be given to the microprocessor. An 8-bit control word is formed for this purpose which may be transferred to the control word register of 8255 through the accumulator.

The control register has 6 control lines $\overline{RD}$, $\overline{WR}$, *RESET*, A_1, A_0 and $\overline{CS}$ whose functions are as given below:

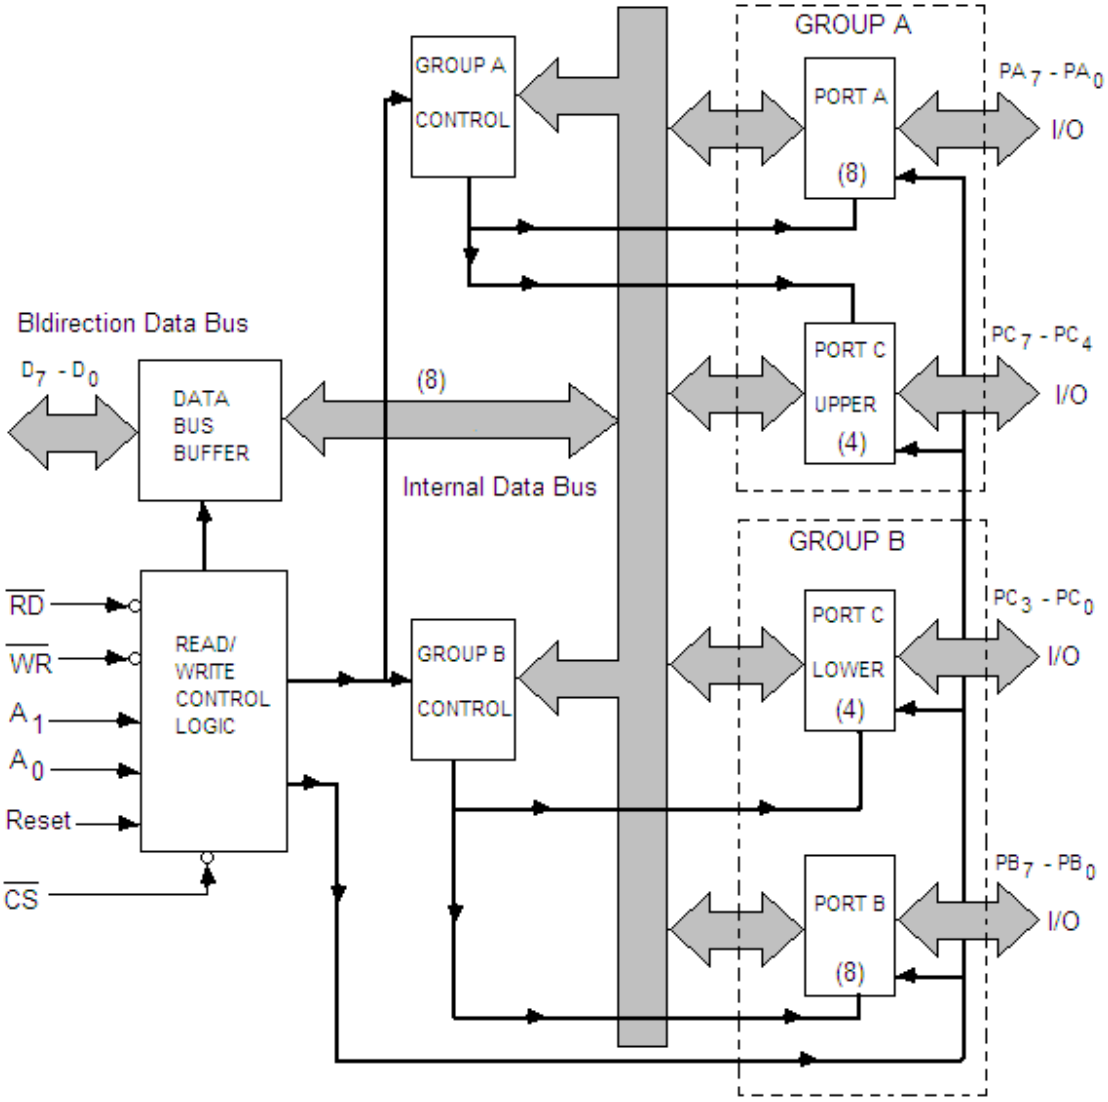

Fig. 8.4

(1) $\overline{\text{RD}}$ (Read): It is a read signal which is active low. When this signal goes low, it allows the microprocessor to read the data from the selected I/O ports of the 8255 PPI.

(2) $\overline{\text{WR}}$ (Write): It is the write signal which is also active low. When this signal goes low, the microprocessor writes (loads) the data into the selected I/O ports or the control register of 8255.

(3) RESET (Reset): This is a reset line which is active high. When a high signal appears on this line, it clears the control register and sets all the ports in the input mode.

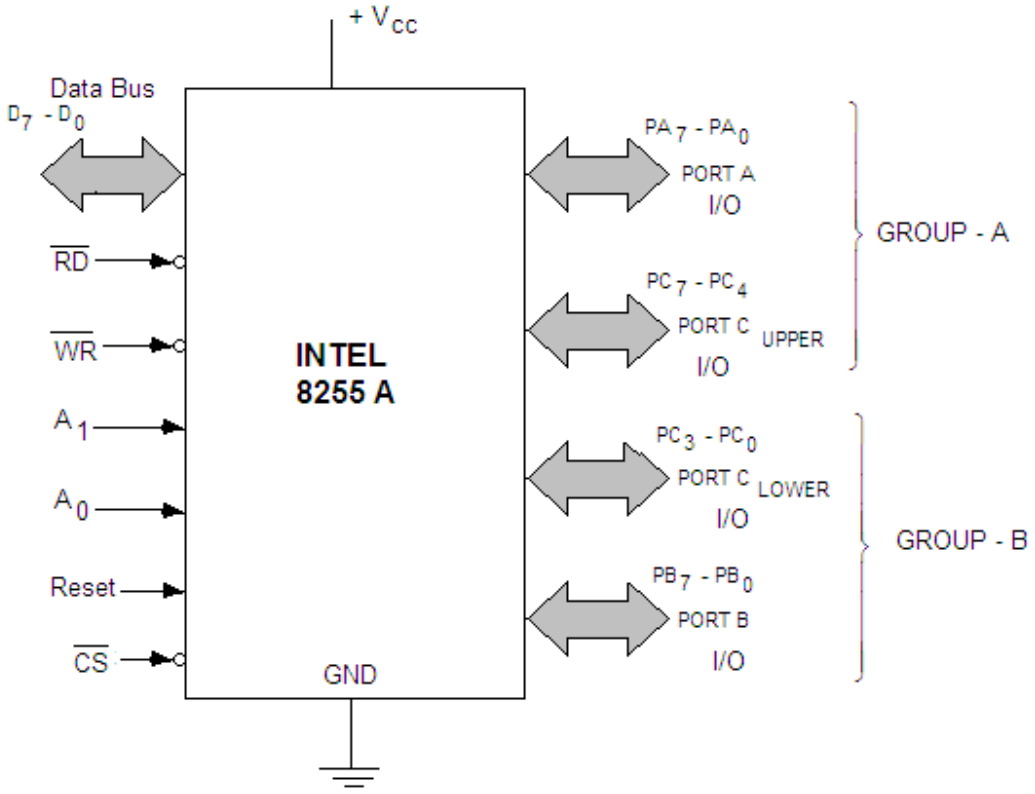

Fig. 8.5

(4) A_0 and A_1: These lines A_0 and A_1 are used to address the three ports and the control word as shown in table 8.1. If the $\overline{CS}$ (chip select) terminal of 8255 is low, the lines A_0 and A_1 decide the ports. The CPU can read or write into these registers by using $\overline{RD}$ and $\overline{WR}$ signals.

Table 8.1

A_1	A_0	
0	**0**	**Port-A**
0	**1**	**Port-B**
1	**0**	**Port-C**
1	**1**	**Control word register**

(5) $\overline{CS}$ (Chip Select): It is an active low chip select terminal. It is used to select 8255 by applying low signal to $\overline{CS}$ terminal. When a high signal appears on this line, the 8255 will not be selected, the data bus buffer that connects 8255 to the system data bus remains floated.

The 6 bits AD_2-AD_7 of address data bus (low order address bus) of the microprocessor are decoded to provide $\overline{CS}$; the remaining two bits AD_0-AD_1 may be used for the selection of control register or any of the three ports as shown in figure 8.6. Since the six bits of address data bus are decoded for $\overline{CS}$, so as many as $2^6 (= 64)$ PPI (8255) can be connected to any system. For the selection of any port of 8255 AD_1 and AD_0 bits of the address data bus are connected to A_1 and A_0 terminals of 8255.

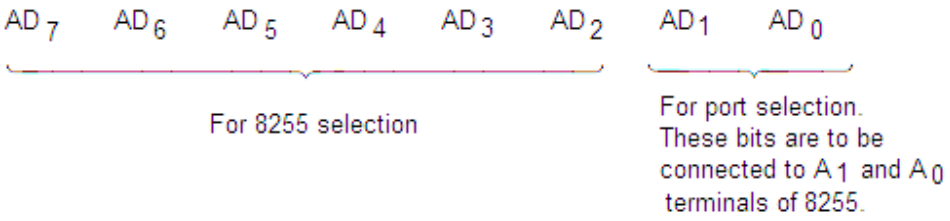

Fig. 8.6

Figure 8.7 shows the chip-select logic for 8255. From this logic diagram it is clear that if AD_7-AD_2 are all 0s then it enables $\overline{CS}$ to select this chip. The port selection will depend on the bits AD_1-AD_0 as given in table 8.2.

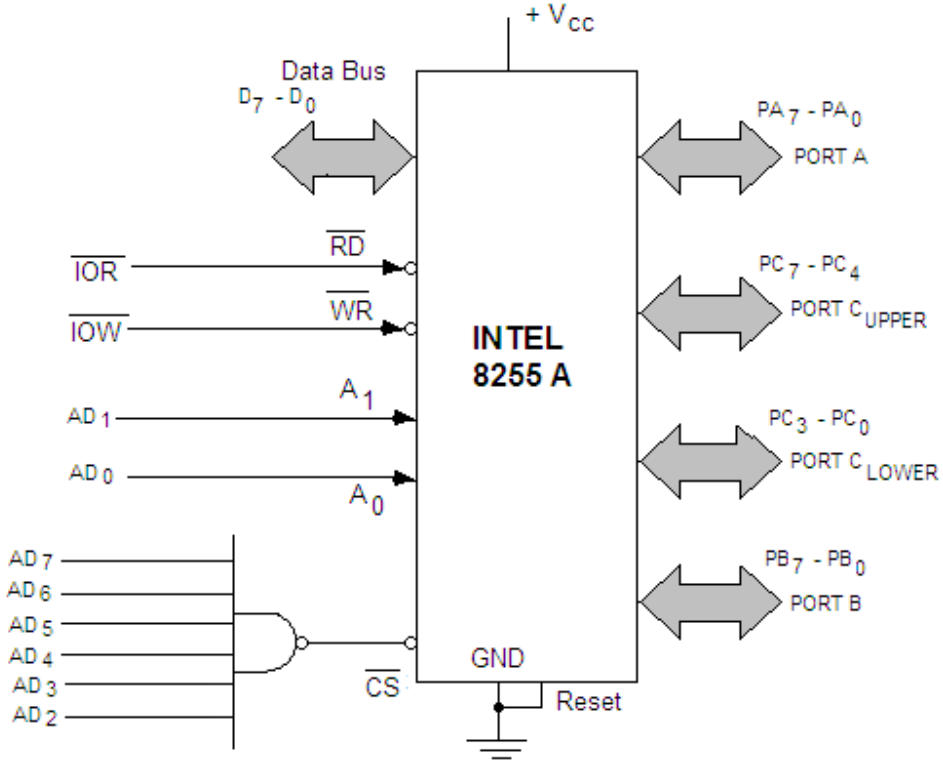

Fig. 8.7

Table 8.2

$\overline{CS}$									
AD_7	**AD_6**	**AD_5**	**AD_4**	**AD_3**	**AD_2**	**AD_1**	**AD_0**	**HEX ADDRESS**	**PORT NAME**
0	0	0	0	0	0	0	0	00 H	Port-A
0	0	0	0	0	0	0	1	01 H	Port-B
0	0	0	0	0	0	1	0	02 H	Port-C
0	0	0	0	0	0	1	1	03 H	Control word Register

Generally the microprocessor kits available with the laboratories have two 8255 connected with the system; 8255-I and 8255-II. Figure 8.8 shows the chip select logic for

the second 8255. If AD_7-AD_2 are chosen as per this diagram then the second 8255 (8255-II) will be selected. The port selection will depend on the bits AD_1-AD_0 as given in table 8.3. The M/S Vinytics, New Delhi has adopted this logic in their microprocessor kits.

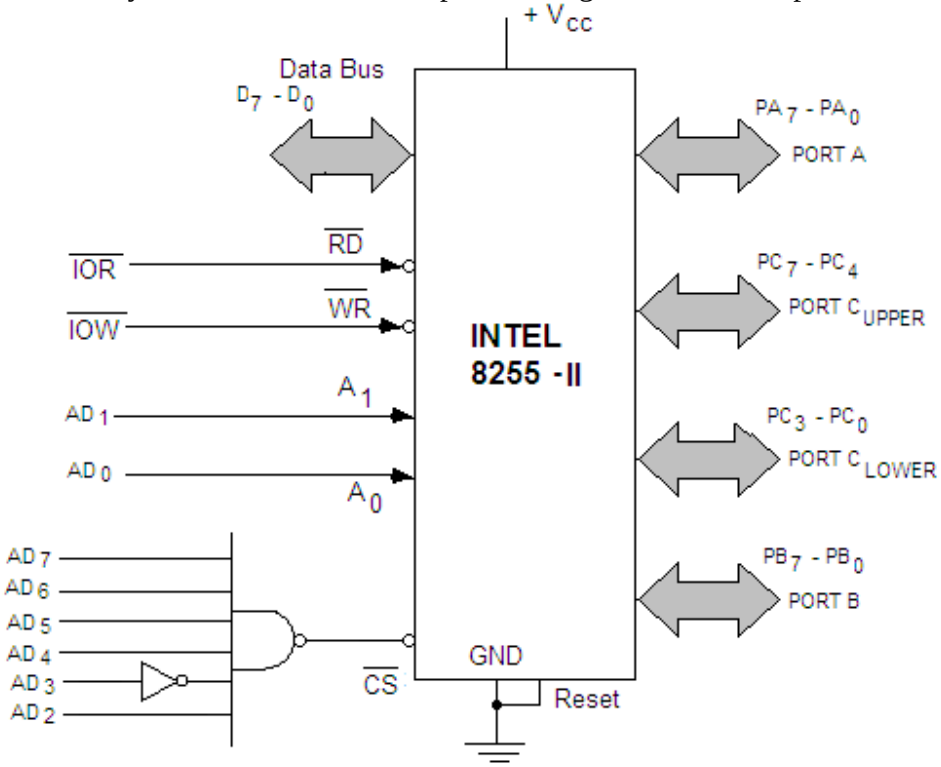

Fig. 8.8

Table 8.3

$\overline{CS}$									
AD_7	**AD_6**	**AD_5**	**AD_4**	**AD_3**	**AD_2**	**AD_1**	**AD_0**	**HEX ADDRESS**	**PORT NAME of 8255-II**
0	0	0	0	1	0	0	0	08 H	Port-A
0	0	0	0	1	0	0	1	09H	Port-B
0	0	0	0	1	0	1	0	0A H	Port-C
0	0	0	0	1	0	1	1	0B H	Control word Register

It may be mentioned here that if the instruction OUT 03 H is executed then it transfers the contents of accumulator to the control word register of 8255-I. Similarly, if the instruction OUT OB H is executed then the accumulator contents will be transferred to control word register of 8255-II. For the control word, accumulator is loaded with the contents that are necessary to use the ports of 8255 as input port or output port. The procedure for the generation of control word will be discussed in a later section of this chapter. Now if 8255-I is initialized to use Port A as input port and ports B and C as output ports, then the execution of IN 00 H instruction will transfer the data from port A

of 8255-I to the accumulator. The execution of OUT 01 H instruction will transfer the accumulator contents to the port B of 8255-I. Similarly, 8255-II may be initialized by giving the proper control word to the control word register by using the instruction OUT 0B H. The IN or OUT instruction having the port address as 08, 09 or 0A may be used for the data transfer through 8255-II.

8.2 OPERATIONAL MODES OF 8255A

The operational modes of 8255 A PPI can be classified into two broad groups (fig. 8.9).

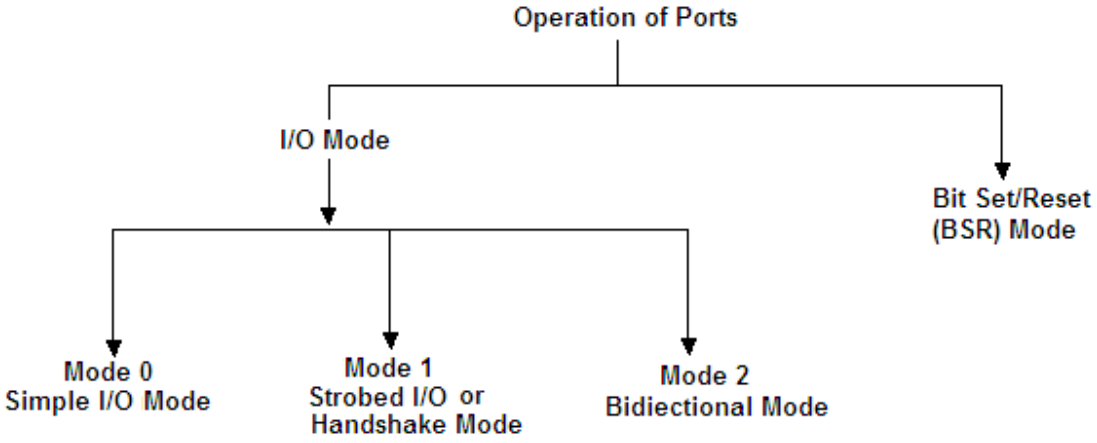

Fig. 8.9

1. I/O Mode

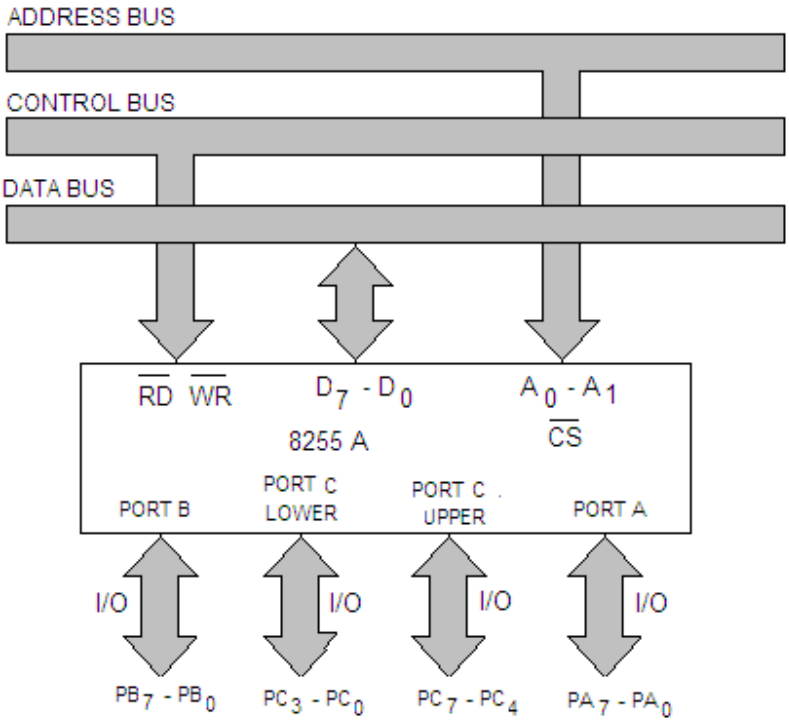
The input/output mode can further be subdivided into three groups:

- **Mode 0 – Simple Input/output mode**

  In this mode the 8 bit port A (PA_0-PA_7) can be configured as input or output port. The port B (PB_0-PB_7) can also be configured, in the similar fashion, as input or output operation. However there is flexibility for the port C. It can be divided into two 4 bit ports, the port C_{Lower} (PC_0-PC_3) and port C_{Upper} (PC_4-PC_7). Each of them can be set independently for input or output operation. In this way there are four ports (port-A, port-B, C_{Lower} and port C_{Upper}) and each of them can be set either as an input port or an output port. Here these ports are simple input or output ports i.e. these ports can work without handshaking. In this mode the outputs are latched whereas the inputs are not latched. The basic definition of this mode is shown in figure 8.10.

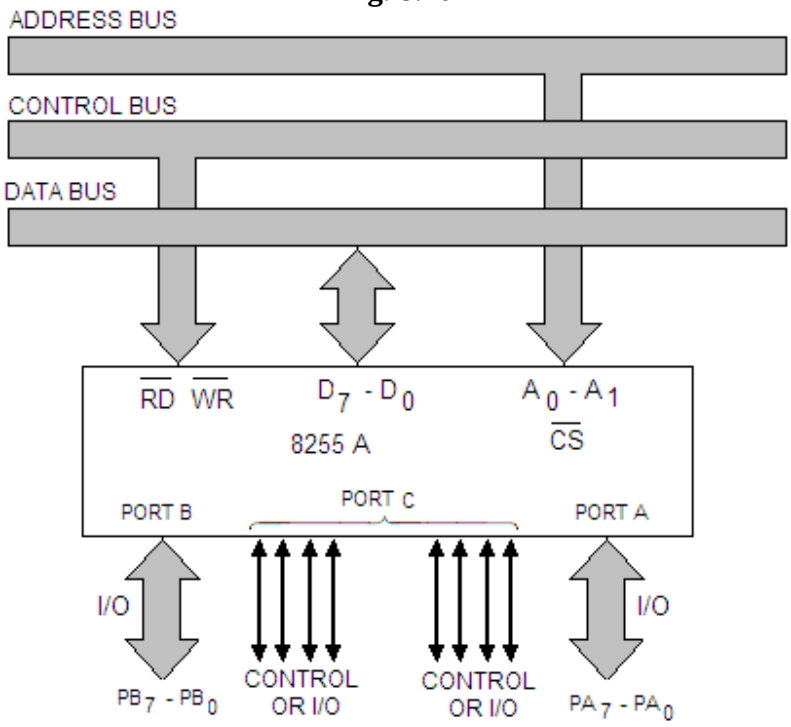
- **Mode 1 – Strobed Input/output or Handshake mode**

  In this mode of operation handshaking is used for the input or output data transfer. As discussed earlier, there are two groups in 8255 PPI: Group A and Group B. Both these groups have one 8-bit port and one 4-bit port. Port-A and Port C_{Upper} form group A whereas Port-B and Port C_{Lower} form group B. The 8-bit port of each group can be programmed for input or output operation with latched input and latched output facilities. The bits of Port C are used for handshaking. Figure 8.11 shows the basic definition of this mode.



Mode-0 Operation

Fig. 8.10



Mode-1 Operation

Fig. 8.11

- **Mode 2 – Bidirectional Mode**

  In this mode Port A can be programmed to operate as a bidirectional port. When Port A is programmed in this mode of operation, Port B can be used either in Mode 0 or Mode 1. For mode 2 operation PC_3 to PC_7 bits are used for handshaking. In this mode too both inputs and outputs are latched. The basic definition of this mode is shown in figure 8.12.

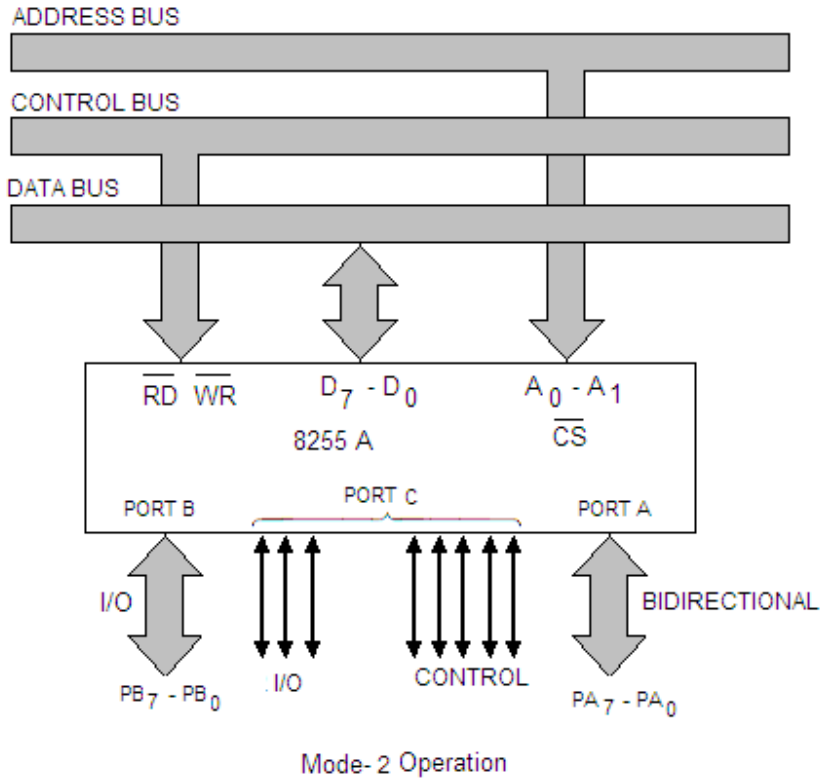


Fig. 8.12

2. Bit Set/Reset Mode

The modes of operation of 8255 PPI may be selected by the software. The details of these modes will be discussed in the following sections.

8.3 CONTROL WORD FORMAT FOR 8255A

As discussed above, a port can be programmed to act as an input port or an output port. A control word is, therefore, to be formed for programming the ports of 8255A. The format for the control word is shown in figure 8.13. The control word, as per the requirement of the programmer, is written into the control word register of 8255A. No read operation of the control word is allowed. The description of the control bits is given below:

Bit D_0 Sets Port C_{Lower} as input or output port.
To make Port C_{Lower} as input port this bit is set to 1.
To make Port C_{Lower} as output port this bit is set to 0.

Bit D_1 Sets Port B as input or output port.
To make Port B as input port this bit is set to 1.
To make Port B as output port this bit is set to 0.

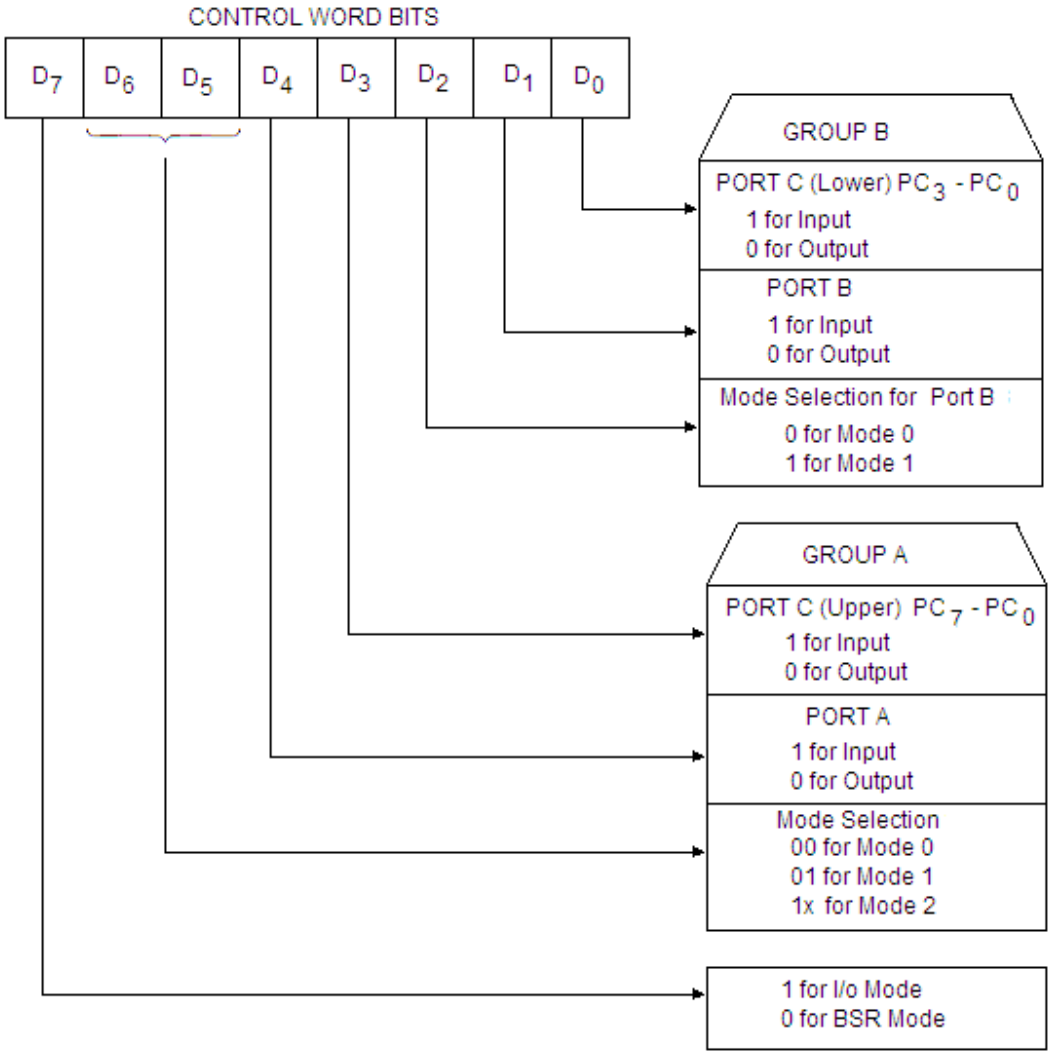

Fig. 8.13

Bit D_2 This bit is for mode selection for the port B.
If this bit is set to 0, the port B will operate in mode 0.
If this bit is set to 1, the port B will operate in mode 1.

Bit D_3 Sets Port C_{Upper} as input or output port.
To make Port C_{Upper} as input port this bit is set to 1.
To make Port C_{Upper} as output port this bit is set to 0.

Bit D_4 Sets Port A as input or output port.
To make Port A as input port this bit is set to 1.
To make Port A as output port this bit is set to 0.

Bits D_5 and D_6 These two bits are used to determine the I/O mode of port A.
These bits are defined for the various modes of port A as follows:

D_6	D_5	Mode of port A
0	0	Mode 0
0	1	Mode 1
1	0 or 1	Mode 2

Bit D_7 This bit specifies either I/O function or bit set/reset function (BSR mode).

If this bit is set to 1 then the 8255 will work in I/O mode.
If this bit is set to 0 then the 8255 will work in BSR mode.

There are 16 combinations of control words for various configurations of the ports of 8255 for Mode 0 operations. These control words are shown in table 8.4.

Table 8.4

Control Word Bits								Control Word	PORT A	PORT C_{Upper}	PORT B	PORT C_{Lower}
D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0					
1	0	0	0	0	0	0	0	80 H	Output	Output	Output	Output
1	0	0	0	0	0	0	1	81 H	Output	Output	Output	Input
1	0	0	0	0	0	1	0	82 H	Output	Output	Input	Output
1	0	0	0	0	0	1	1	83 H	Output	Output	Input	Input
1	0	0	0	1	0	0	0	88 H	Output	Input	Output	Output
1	0	0	0	1	0	0	1	89 H	Output	Input	Output	Input
1	0	0	0	1	0	1	0	8A H	Output	Input	Input	Output
1	0	0	0	1	0	1	1	8B H	Output	Input	Input	Input
1	0	0	1	0	0	0	0	90 H	Input	Output	Output	Output
1	0	0	1	0	0	0	1	91 H	Input	Output	Output	Input

1	0	0	1	1	0	1	1	9B H	Input	Input	Input	Input

8.4 PROGRAMMING IN MODE 0

As discussed earlier, the Ports A, B, and C can be configured as simple input or output ports by writing the appropriate control word in the control word register. In the control word D_7 is set to 1 as 8255A is to be used in simple I/O mode, D_6, D_5 and D_2 are

all set to 0 as all the ports are to be used in mode 0. The remaining bits D_4, D_3, D_1 and D_0 determine if the corresponding ports are to be used as input port or output port (1 for input port and 0 for output port). Since these are four bits to decide which ports are to be used as input ports and which ports are to be used as output ports, so for this purpose, there will be 16 possible combinations of control words listed in table 8.4.

For example, the control word when the ports of 8255A PPI are to be used in mode 0 with Port A as input port, port B as output port, Port C_{Upper} as output port and Port C_{Lower} as input port is given as:

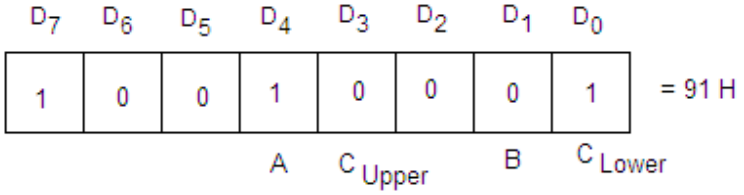

Fig. 8.14

The control word 91 H is to be loaded to the control word register (CWR) of 8255A through the OUT instruction. Let the control word 91 H is to be loaded to control word register of 8255-I connected to the system (port address is 03 H discussed earlier). It may be done with the following instructions:

MVI A, 91 H
OUT 03 H

Now with OUT or IN instructions, the data may be transferred to or from the output devices. The proper port address is to be given with these instructions.

Example 8.1. *Obtain the control word when the ports of 8255A are to be used in mode 0 with port-A as input port and port B and port C as output port.*

Solution. The control word for this case is given as:

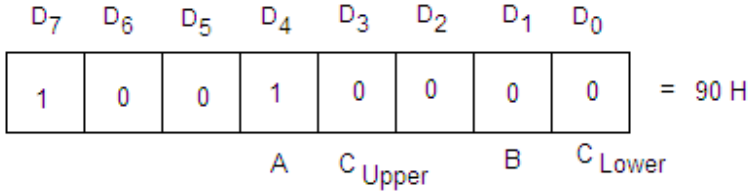

Fig. 8.15

Example 8.2. *Obtain the control word when the ports of 8255A are to be used in mode 0 with port-A as output port and port B as input port and port C as output port.*

Solution. The control word for this case is given as:

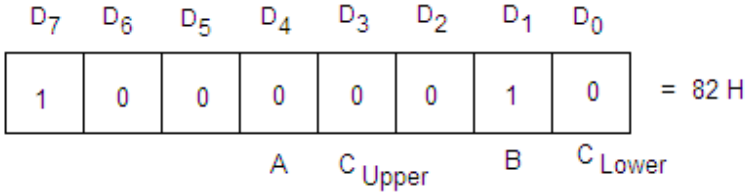

Fig. 8.16

Example 8.3. *Make control word when the ports of 8255A are to be used in mode 0 with all the ports as output ports.*

Solution. The control word for this case is given as:

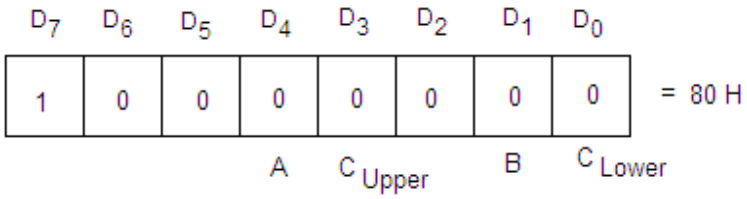

Fig. 8.17

Example 8.4. *Write an assembly language program to generate a square ware of 1 KHz frequency using 8255A. The wave should be available at PA_0 terminal of Port-A.*

Solution. The Program to perform the task given in the problem is shown below:

MAIN PROGRAM:

Label	**Mnemonics**	**Operand**	**Comments**
	MVI A,	80 H	; Initialize 8255-I to work all the ports as output ports.
	OUT	03 H	; Write the control word (80 H) in the control word register of 8255-I.
LOOP	MVI A,	00 H	; Load 00 H to accumulator.
	OUT	00 H	; Send 00H (0V) to PA_0.
	CALL	DELAY	; Jump to dealy subroutine to introduce a delay of 0.5 msec.
	MVI A,	01 H	; Load 01H to accumulator.
	OUT	00 H	; Send 01 H (5V) to PA_0.
	CALL	DELAY	; Jump to dealy subroutine to introduce a delay of 0.5 msec.
	JMP	LOOP	; Jump to loop to repeat the process.

SUBROUTINE PROGRAM:

Label	**Mnemonics**	**Operand**	**Comments**
DELAY	LXI D,	003FH	; Loads DE register pair with a 16-bit number (63_{10}).
LOOP1	DCX D		; Decrements DE register pair by 1.
	MOV A,	E	; Moves the contents of E register to accumulator.
	ORA D		; ORing of the contents of D and E registers are performed to set the zero flag.
	JNZ	LOOP1	; If result is not zero than jump to LOOP1.
	RET		; Go back to main program.

The subroutine program introduces a delay of approximately 0.5 msec (discussed in section 4.3). The PA_0 terminal will be low for 0.5 msec and high for 0.5 msec. The total time will be 1 msec and thus a signal of 1 KHz will be generated at PA0 of port-A. A CRO may be connected to this terminal to observe the wave.

Example 8.5. *Write an assembly language program to glow 8-LEDs sequentially with a delay of one second. The LEDs are connected to 8 bits of port-B of 8255-II attached with the system.*

Solution. The program to perform the task of the problem is given below:

MAIN PROGRAM:

Label	Mnemonics	Operand	Comments
	MVI A,	80 H	; Initialize 8255-II to work all the ports as output ports.
	OUT	0B H	; Write the control word in the control word register of 8255-II.
	MVI A,	01 H	; Load 01 H to accumulator.
REPEAT	OUT	09 H	; Send 01H (5V) to PB_0 for the glow of LED
	CALL	DELAY	; Jump to delay subroutine - to introduce a delay of 1 sec.
	RLC		; Rotate the contents of accumulator left for sequential glow of LEDs.
	JMP	REPEAT	; Jump to Repeat for the next LED to glow.

SUBROUTINE PROGRAM:

Label	Mnemonics	Operand	Comments
DELAY	PUSH PSW		; Send the contents of Acc and flag register to stack.
	MVI C,	02 H	; Load C register with 02 H data.
LOOP	LXI D,	F424 H	; Loads DE register pair with a 16-bit number (63_{10}).
LOOP1	DCX D		; Decrements DE register pair by 1.
	MOV A,	E	; Moves the contents of E register to accumulator.
	ORA D		; ORing of the contents of D and E registers are performed to set the zero flag.
	JNZ	LOOP1	; If result is not zero than jump to LOOP1.
	DCR C		; Decrement the contents of C register.
	JNZ	LOOP	; If the result is not zero Jump to LOOP.
	POP PSW		; Acc and flag contents are popped from the stack.
	RET		; Go back to main program.

The subroutine program given here is already discussed in section 4.3.

In place of RLC in the main program RRC may be written, which will allow the LEDs to glow in the opposite sequence.

Example 8.6. *Write a program in assembly language of 8085, to switch on an a.c. bulb after a delay of 1 Min. A relay circuit may be connected to PA_0 of 8255-I to switch on the bulb.*

Solution. The relay circuit may be connected to PA_0 of 8255A as shown in figure 8.18. When PA0 is made high (through software), the transistor T_1 goes into saturation and thus energizes the relay. The normally open (N/O) terminals of the relay get connected

together and the bulb may be switched on. To provide high (logic 1) to PA0, the program in assembly language of 8085 is written as:

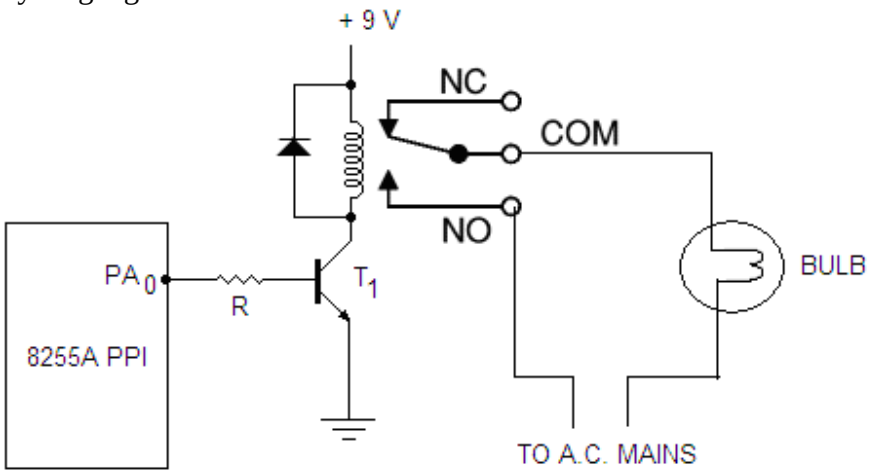

Fig. 8.18

MAIN PROGRAM:

Label	**Mnemonics**	**Operand**	**Comments**
	MVI A,	80 H	; Initialize 8255-I to work all the ports as output ports.
	OUT	03 H	; Write the control word in the control word register of 8255-I.
	MVI A,	00 H	; Load 00 H to accumulator.
	OUT	00 H	; Send 00H (0V) to PA_0 for the bulb to remain OFF.
	CALL	DELAY	; Jump to delay subroutine - to introduce a delay of 1 Min.
	MVI A,	01 H	; Load 01 to accumulator.
	OUT	00 H	; Send 01 (5V) to PA0 for the bulb to ON.
	HLT		

SUBROUTINE PROGRAM:

Label	**Mnemonics**	**operand**	**Comments**
DELAY	MVI C,	78 H	; Load C register with 78 H (120_{10})data so that the delay of 0.5sec is run 120 times (60sec).
LOOP	LXI D,	F424 H	; Loads DE register pair with a 16-bit number (63_{10}).
LOOP1	DCX D		; Decrements DE register pair by 1.
	MOV A,	E	; Moves the contents of E register to accumulator.
	ORA D		; ORing of the contents of D and E registers are performed to set the zero flag.
	JNZ	LOOP1	; If result is not zero than jump to LOOP1.

```
        DCR  C                  ; Decrement the contents of C
                                  register.
        JNZ      LOOP           ; If the result is not zero Jump to
                                  LOOP.
        RET                     ; Go back to main program.
```

Example 8.7. *Eight switches are connected to 8 bits of 8255 A (assume that the switches are debouncer switches) and 8 LEDs are connected to the 8 bits of Port B of 8255 A. Write an assembly language program that whenever any of the switch is depressed the corresponding LED glows. For example, if the switch number 3 is switched on, the LED connected to bit 3 should glow; similarly for the other.*

Solution. The program to perform the task of the problem is given below:

MAIN PROGRAM:

Label	Mnemonics	Operand	Comments
	MVI A,	99 H	; Initialize 8255-I to make port A and port C as input ports and port B as output port.
	OUT	03 H	; Write the control word in the control word register of 8255-I.
REPEAT	IN	00 H	; Send 01H (5V) to PB_0 for the glow of LED
	OUT	01 H	; Output the input data to glow the LED corresponding to depressed switch.
	JMP	REPEAT	; Jump to Repeat.

8.5 PROGRAMMING IN MODE 1 (STROBED INPUT/OUTPUT)

As already discussed, in Mode 1 handshake (Strobes) signals are used for the data transfer between the microprocessor and I/O devices. The handshake signals are exchanged between the microprocessor and peripherals. Both group A and group B of 8255 can be made to operate in Mode 1. The two ports (Port A and Port B) can be configured either as input port or output port. Each port (Port A and Port B) uses three lines of port C as handshake signals (i.e. total 6 lines of port C are used for handshake signals). The remaining two lines of port C can be used for simple I/O operation.

Bits PC_0, PC_1 and PC_2 of port C are used as handshake signals for port B in input and output modes. Bits PC_3, PC_4 and PC_5 of port C are used as handshake signals for port-A in input mode only. The remaining bits of port C (PC_5 and PC_6) are used as simple I/O operation as programmed by bit D_3 of the control word.

Bits PC_3, PC_6 and PC_7 of port C are used as control (handshake) signals for port A in output mode. In this case bits PC_4 and PC_5 of port C are used as simple I/O operation as programmed by bit D_3 of the control word. The remaining bits PC_0, PC_1 and PC_2 of port C are used for handshake signals for port B.

The combination of Mode 1 and Mode 0 operation is also possible. For example, when port A is programmed to operate in mode 1, the port B can be operated in mode 0.

8.5.1 Input Control Signals in Mode 1

Figure 8.19(a) shows the input configuration of both Port A and Port B to be used in mode 1. The control signals used for handshaking are also shown in this figure. Bits

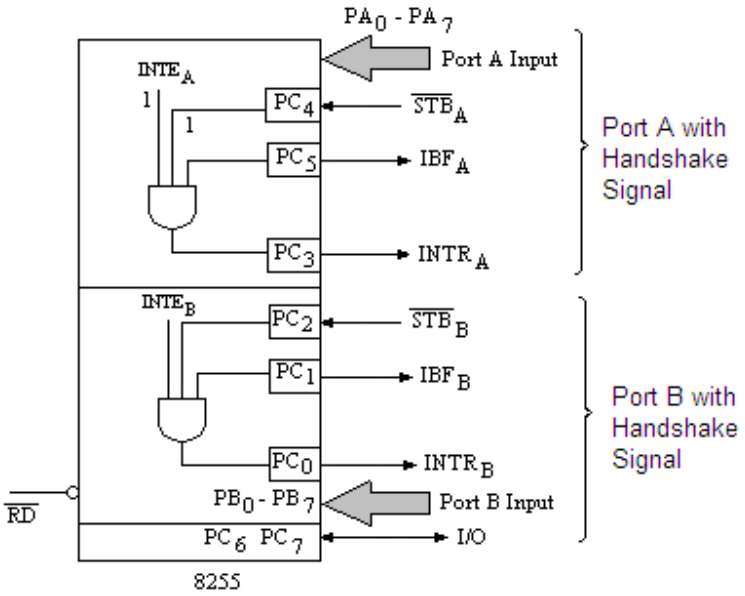
PC_3, PC_4 and PC_5 of port C are used for handshaking when port A is used as input port; and bits PC_0, PC_1 and PC_2 are used for handshaking when port B is also used for input port. Bits PC_6 and PC_7 are used for simple input/output operation. The control word for using Port A and Port B as input ports in mode 1 is shown in figure 8.19(b).

The functions of three control signals used for handshaking are given as:

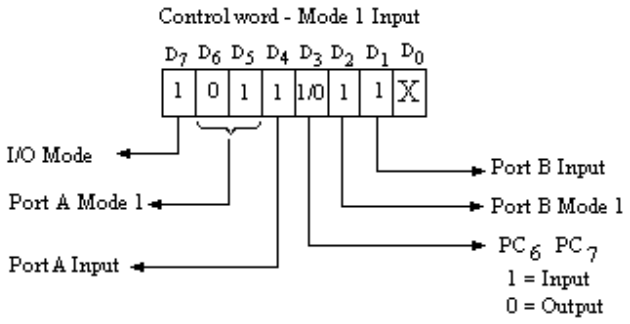
$\overline{\text{STB}}$ (Strobe Input) This is an active low signal generated by the peripheral device to indicate that it has transmitted a byte of data. In response to this signal, 8255 generates IBF (Input Buffer Full) and INTR (Interrupt Request) signals.

IBF (Input Buffer Full) This is an acknowledge signal sent by 8255. A high to this signal indicates that the input latch has received the data byte.

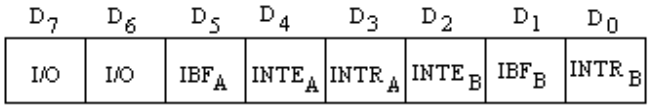
INTR (Interrupt Request) This is an output signal sent by 8255 which may be used to interrupt the microprocessor. This signal is generated when $\overline{\text{STB}}$, IBF and INTE (Interrupt Enable) are all low (logic 0). At the falling edge of the $\overline{\text{RD}}$ signal, this is reset.



(a)

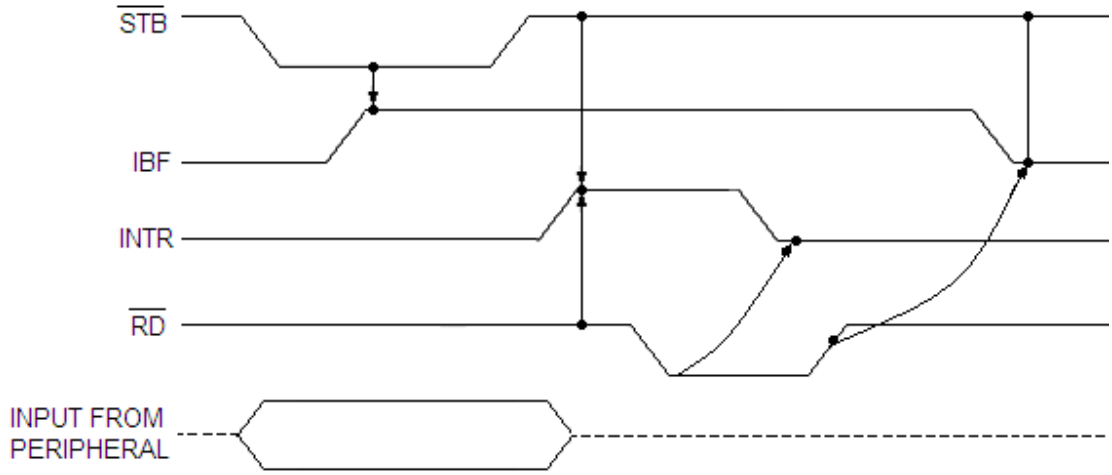


(b)



Status Word - Mode 1 Input

(c)



(d) **Fig. 8.19**

INTE (Interrupt Enable) This is an internal flip-flop which is used to enable or disable the generation of INTR signal. The two flip-flops $INTE_A$ and $INTE_B$ are set/reset using the BSR mode. The bit PC_4 enables or disables $INTE_A$; and PC_2 enables or disables $INTE_B$.

Figure 8.19(c) shows the status word (i.e. the status of the signals INTR, INTE and IBF signals etc.) which will be placed in the accumulator if the port C is read.

As shown in figure 8.19(d), the peripheral first loads data into the input port A or B by making $\overline{STB}$ input low. This low $\overline{STB}$ signal is generated by the peripheral device to indicate that it has transmitted a byte of data. The 8255A generates IBF and INTR in response to the active low $\overline{STB}$ signal.

8.5.2 Output Control Signals in Mode 1

As already discussed Bits PC_3, PC_6 and PC_7 of port C are used as control (handshake) signals for port A in output mode. In this case bits PC_4 and PC_5 of port C are used as simple I/O operation as programmed by bit D_3 of the control word. The remaining bits PC_0, PC_1 and PC_2 of port C are used for handshake signals for port B.

Figure 8.20(a) shows the input configuration of both Port A and Port B to be used in mode 1. The control signals used for handshaking are also shown in this figure. Bits PC_3, PC_6 and PC_7 of port C are used for handshaking when port A is used as output port; and bits PC_0, PC_1 and PC_2 are used for handshaking when port B is also used for output port. Bits PC_4 and PC_5 are used for simple input/output operation. The control word for using Port A and Port B as input ports in mode 1 is shown in figure 8.20(b).

The functions of three control signals used for handshaking are given as:

$\overline{OBF}$ (Output Buffer Full) This is an active low signal; it activates when the microprocessor writes data into output latch of 8255. This

indicates to an output peripheral that a new data is ready to be read. It goes high again after the 8255 receives a $\overline{ACK}$ signal from peripheral.

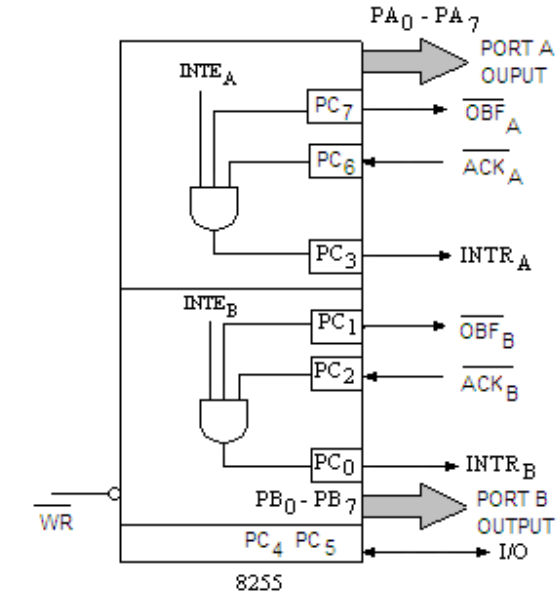
$\overline{ACK}$ (Acknowledge) This is an input signal from a peripheral. It becomes active (low) when peripheral receives the data from 8255 ports.

INTR (Interrupt Request) This is an output signal which is set at the rising edge of the $\overline{ACK}$ signal. This signal can be used to interrupt the microprocessor. It requests for the next data byte for output. This signal is generated when $\overline{OBF}$, $\overline{ACK}$ and INTE (Interrupt Enable) are all high (logic 1). At the falling edge of the $\overline{WR}$ signal this is reset.

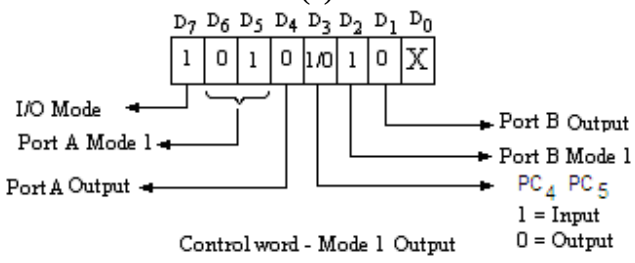
INTE (Interrupt Enable) This is an internal flip-flop to a port and required to be set to generate the INTR signal. The two flip-flops $INTE_A$ and $INTE_B$ are set/reset using the BSR mode.

Figure 8.20(c) shows the status word (i.e. the status of the signals INTR, INTE and OBF signals etc.) which will be placed in the accumulator if the port C is read.

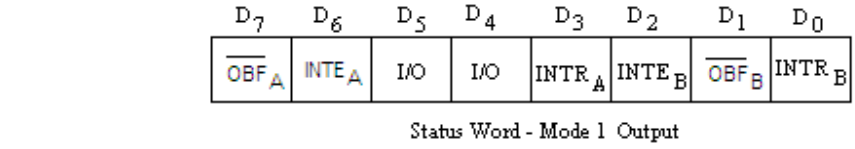
Figure 8.20(d) shows the timing diagram for strobed Output.



(a)

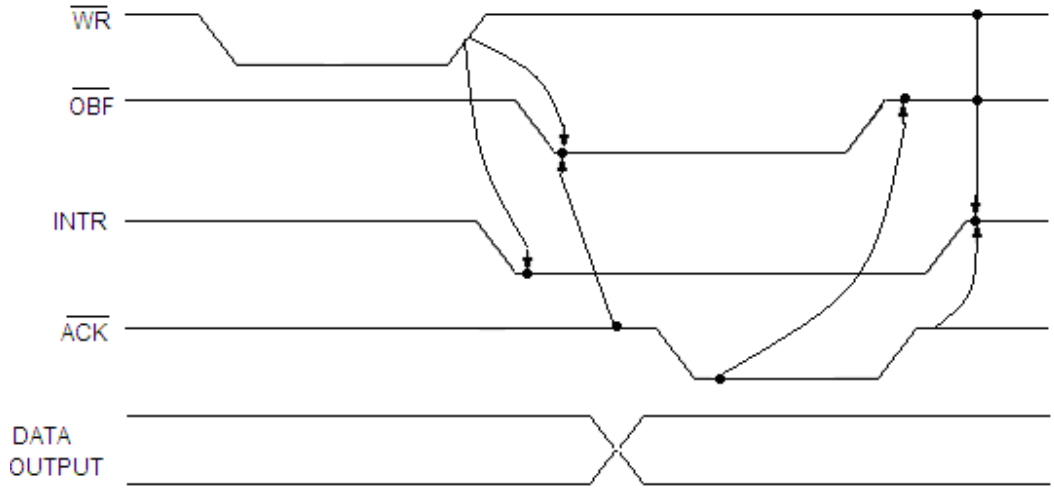


(b)



Status Word - Mode 1 Output

(c)

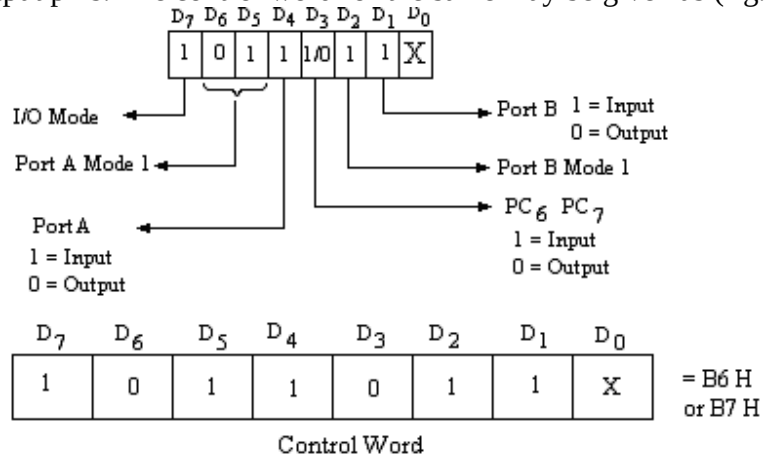


(d) **Fig. 8.20**

Example 8.8. *Obtain the control word for the following configuration of the ports of 8255 A for mode 1 operation:*

Port A – as input port,
Mode for Port A – mode 1
Port B – input port
Mode for Port B – mode 1,
The remaining pins of port C_{Upper} *are to be used output pins.*

Solution. The 8255 A is to be used in mode 1, and port A as input port so PC_3, PC_4 and PC_5 pins of port C will be used as the handshake signals. For port B as input port the PC_0, PC_1 and PC_2 pins of port C will be used as the handshake signals. The remaining pins of port C_{Upper} will be used as simple input output mode. In the present example PC_6 and PC_7 are to be used as output pins. The control word for the same may be given as (fig. 8.21):



Control Word

Fig. 8.21

Example 8.9. *Obtain the control word for the following configuration of the ports of 8255 A for mode 1 operation:*

Port A – as output port,
Mode for Port A – mode 1
Port B – output port,
Mode for Port B – mode 1,
The remaining pins PC_4 and PC_5 of port C are to be used input pins.

Solution. The 8255 A is to used in mode 1, and port A as output port so PC_3, PC_6 and PC_7 pins of port C will be used as the handshake signals. For port B as output port the PC_0, PC_1 and PC_2 pins of port C will be used as the handshake signals. The remaining pins of port C will be used as simple input output mode. In the present example PC_4 and PC_5 are to be used as input pins. The control word for the same may be given as (fig. 8.22):

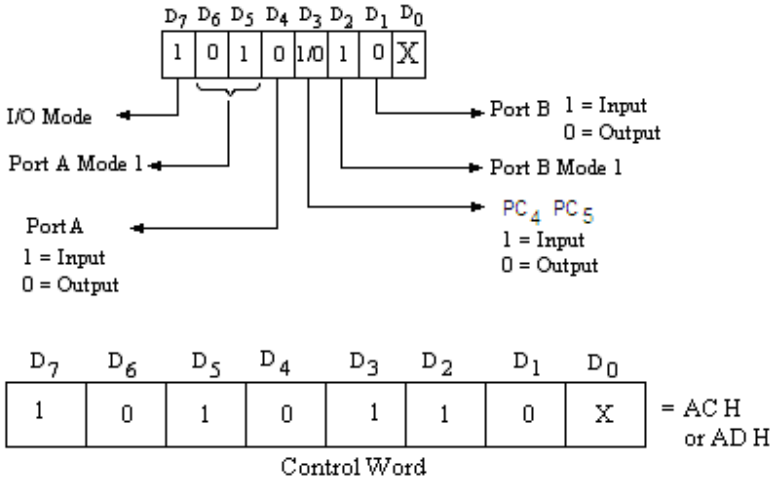


Fig. 8.22

Example 8.10. *Obtain the control word for the following configuration of the ports of 8255 A:*

Port A – as input port,
Mode for Port A – mode 1
Port B – input port,
Mode for Port B – mode 0,
Port C_{Lower} – output port
The remaining pins PC_6 and PC_7 of port C are to be used input pins.

Solution. The 8255 A is to used in mode 1 and mode 0, and port A as input port in mode 1 so PC_3, PC_6 and PC_7 pins of port C will be used as the handshake signals. The port B is to be used as input port in mode 0. The Port C_{Lower} is used as output port and remaining bits of port C (PC_6, PC_1) as input pins. The control word for the same may be given as (fig. 8.23):

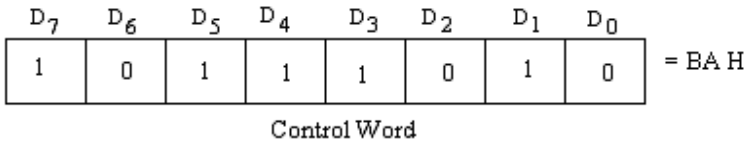

Fig. 8.23

8.6 PROGRAMMING IN MODE 2 (STROBED BIDIRECTIONAL BUS I/O)

In mode 2 operation of 8255A, port A can be used as bidirectional 8 bit I/O bus. The port B can operate in mode 0 or mode 1.

When port A is programmed to operate in mode 2 (bidirectional I/O bus), the five bits of port C (PC_3-PC_7) are used as control (handshake) signals for port A. This is illustrated in figure 8.24. In this case port B can be programmed in mode 0 or mode 1. If port B is used in mode 0, the remaining bits of port C (PC_0-PC_2) are used as input or output. However, if port B is used in mode 1, PC_0-PC_2 bits are used as handshake signals for port B.

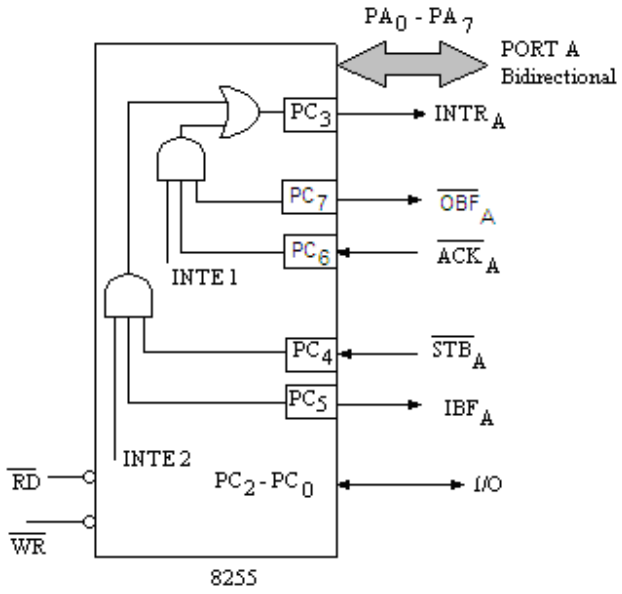

Fig. 8.24

The functions of five control signals used for handshaking of port A are given as:

$\overline{\text{STB}}$ (Strobe Input) This is an active low signal generated by the peripheral device to indicate that it has transmitted a byte of data. In response to this signal, 8255 generates IBF (Input Buffer Full) and INTR (Interrupt Request) signals.

IBF (Input Buffer Full) This is an acknowledge signal sent by 8255. A high to this signal indicates that the input latch has received the data byte.

INTR (Interrupt Request) This is an output signal which is set at the rising edge of the $\overline{\text{ACK}}$ signal. This signal can be used to interrupt the microprocessor. It requests for the next data byte for output. This signal is generated when $\overline{\text{OBF}}$, $\overline{\text{ACK}}$ and INTE (Interrupt Enable) are all high (logic 1). At the falling edge of the $\overline{WR}$ signal this is reset.

INTE (Interrupt Enable) This is an internal flip-flop to a flip-flop to a port and required to be set to generate the INTR signal. The two flip-flops $INTE_1$ and $INTE_2$ are set/reset using the BSR mode.

$\overline{\text{OBF}}$ (Output Buffer Full) This is an active low signal; it activates when the microprocessor writes data into output latch of 8255. This indicates to an output peripheral that a new data is ready to be read. It goes high again after the 8255 receives a $\overline{\text{ACK}}$ signal from peripheral.

If all the possible combinations are considered, then there will be four configurations of the 8255A in mode 2. These combinations with their corresponding control words are shown in figures 8.25 to 8.28. The status word in mode 2 is shown in figure 8.29, which will be placed in the accumulator if the port C is read.

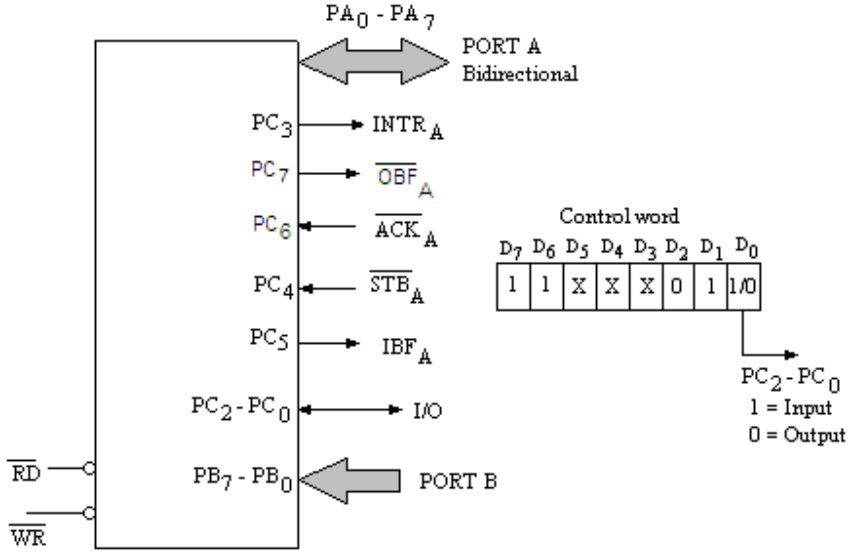

Fig. 8.25

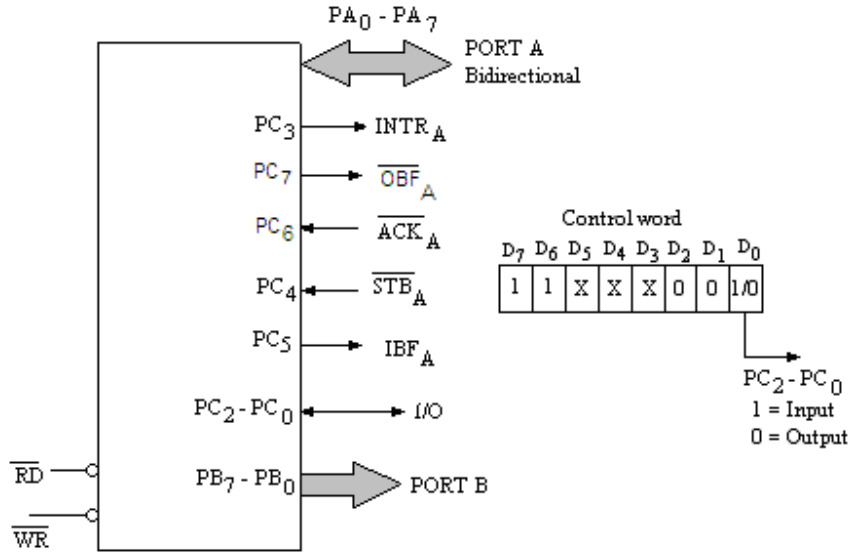

Fig. 8.26

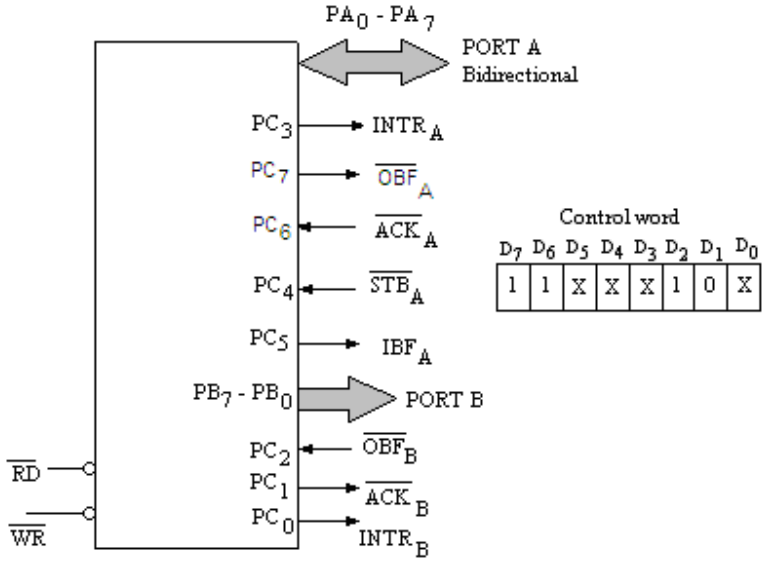

Fig. 8.27

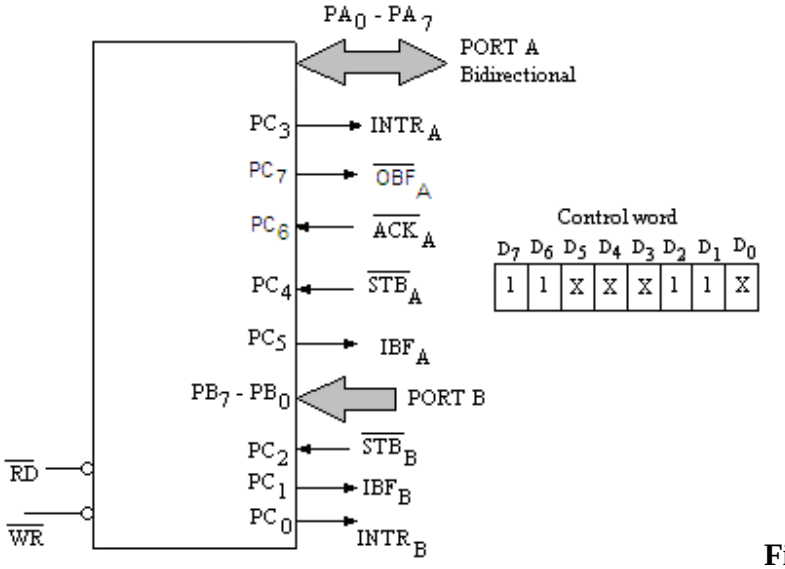

Fig. 8.28

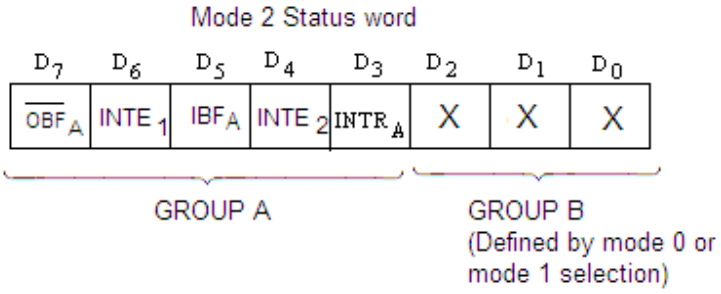

Fig. 8.29

Example 8.11. *Obtain the control word for the following configuration of the ports of 8255 A:*

Port A – as bidirectional,
Mode for Port A – mode 2
Port B – input port,
Mode for Port B – mode 0,
Port C_{Lower} – input port

Solution. . It may be remembered that the 8255 A is used in mode 2 only for port A. When port A is used to operate in mode 2; port B can be used either in mode 0 or mode 1. The pins of port C (PC_3 to PC_7) are used for the control signals for port A. For port B to operate in mode 0, Port C_{Lower} can be used as input or output pins as per the D_0 bit of the control word. On the other hand for the port B to operate in mode 1, PC_0, PC_1 and PC_2 bits will be used for control signals.

The control word for this case is given as (fig. 8.30):

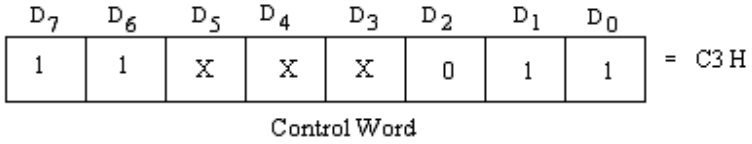

Fig. 8.30

Example 8.12. *Obtain the control word for the following configuration of the ports of 8255 A:*

Port A – as bidirectional,
Mode for Port A – mode 2
Port B – input port,
Mode for Port B – mode 1,

Solution.

The control word for this case is given as (fig. 8.31):

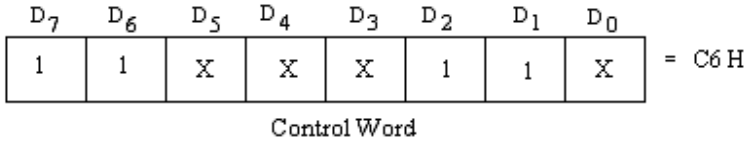

Fig. 8.31

8.7 BIT SET/RESET (BSR) MODE

As discussed in the earlier sections of this chapter that 8255A PPI can be used in bit set/reset (BSR) mode. To use the PPI in BSR mode D_7 bit of the control word should be set to zero. However, for other mode of operations this bit should be set to 1. In BSR mode eight bits of Port C can be set or reset by writing the control word in the control word register. If a control word with bit D_7 as 0 is recognized as a BSR mode then it does not alter any previously transmitted control word with D_7 as 1; thus I/O operations are not affected by a BSR control word. In this mode of operation individual bit of port C can be set or reset or in other words a BSR control word affects only one bit of port C. The control word format for this mode of operation is shown in figure 8.32.

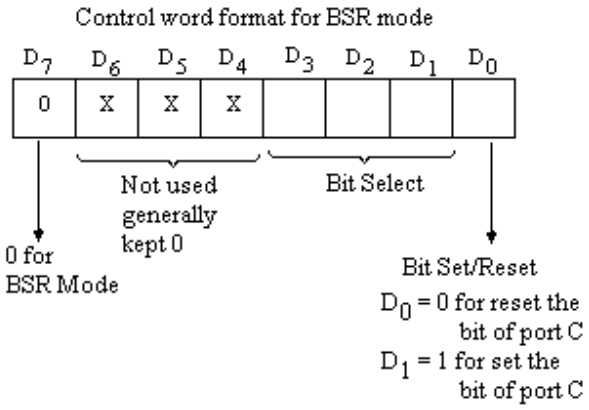

Fig. 8.32

The bits of the control word are defined as:

Bit D_7 This bit should be zero, to use 8255A in bit set/reset mode.

Bits D_4-D_6 These bits are don't care bits, which may be kept 0s or 1s but generally kept 0.

Bits D_1-D_3 The bits D_3, D_2 and D_1 are known as bit select pins. Table 8.5 shows which bit of port C will be affected by the D_3, D_2 and D_1 bits of bit select pins.

Table 8.5

D3	D2	D1	Bit of port C
0	0	0	PC_0
0	0	1	PC_1
0	1	0	PC_2
0	1	1	PC_3
1	0	0	PC_4
1	0	1	PC_5
1	1	0	PC_6
1	1	1	PC_7

Bit D_0 This is known as Set reset bit. To set a bit of port C, D_0 bit of the control word should be 1; and to reset a bit of port C, D_0 of the control word should be 0.

For example to reset PC_3 (bit 3 of port C), the control word format will be given as:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	0	0	0	0	1	1	0	= 06 H

Bit 3 (PC_3)

Similarly, to set PC3, the control word format is given as:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	0	0	0	0	1	1	1	= 07 H

Bit 3 (PC_3)

Example 8.13. *A relay circuit, to switch on or off an a.c. mains bulb, is connected to PC_4 (4^{th} bit of port C). The 8255A is connected microprocessor whose address for control*

word is 03 H. Using BSR mode it is desired to switch on and off the bulb after a regular interval of time. W rite a program in assembly language of 8085, to implement the above.

Solution. The relay circuit may be connected to PC_4 of 8255A as shown in figure 8.33. To switch on and off the bulb regularly using BSR, the program in assembly language of 8085 is written as:

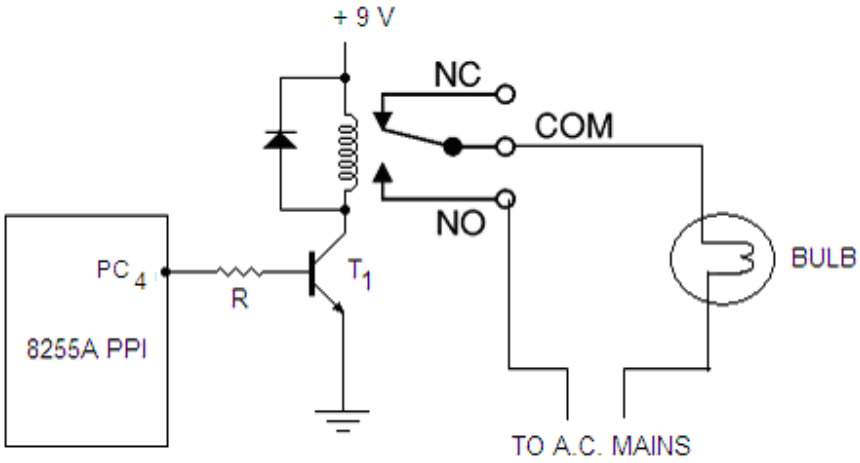

Fig. 8.33

The control word in BSR mode to reset PC_4 bit is:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	0	0	0	1	0	0	0	= 08 H

The control word in BSR mode to set PC_4 bit is:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	0	0	0	1	0	0	1	= 09 H

MAIN PROGRAM:

Label	**Mnemonics**	**Operand**	**Comments**
	LXI SP,	XXXX H	; Initialize stack pointer.
START	MVI A,	08 H	; Load byte in accumulator to reset PC_4.
	OUT	03 H	; Reset PC_4 (the bulb will be off).
	MVI A,	08 H	; Load 08 H to accumulator.
	OUT	03 H	; Reset PC_4 (the bulb will be off).
	CALL	DELAY	; Jump to delay subroutine - to introduce a regular delay of constant time.
	MVI A,	09 H	; Load 09 to accumulator to set PC_4.
	OUT	03 H	; Set PC_4 (the bulb will be on).
	CALL	DELAY	; Jump to delay subroutine - to introduce a regular delay of constant time.
	JMP	START	; Jump to repeat the process.

SUBROUTINE PROGRAM:

Label	**Mnemonics**	**Operand**	**Comments**

```
DELAY   LXI  D,     XXXX H    ; Loads DE register pair with a 16-
                               bit number.
LOOP    DCX  D                ; Decrements DE register pair by 1.
        MOV  A,     E         ; Moves the contents of E register to
                               accumulator.
        ORA  D                ; ORing of the contents of D and E
                               registers are performed to set the
                               zero flag.
        JNZ         LOOP      ; If result is not zero than jump to
                               LOOP1.
        RET                   ; Go back to main program.
```

XXXX H may be taken any hexadecimal number for introducing any desired delay.

Example 8.14. *Write a program in assembly language of 8085 to send 01H, 02H, 03H . . . . . FFH data to port A of 8255A PPI with a time delay of 1msec to each output.*

Solution. The program to implement the above is given as:

```
Label     Mnemonics   Operand    Comments
          LXI  SP,    XXXX H     ; Initialize stack pointer.
          MVI  A,     80 H       ; Initialize 8255-I to work all the
                                   ports as output ports.
          OUT         03 H       ; Write the control word in the
                                   control word register of 8255-I.
          MVI  A,     00 H       ; Load 00 H to accumulator.
          MVI  B,     FF H       ; Load FF H to B-reg (last data).
LOOP      INR  A                 ; Increment acc.
          OUT         00 H       ; Send the number to port A.
          CALL        DELAY      ; Jump to delay subroutine - to
                                   introduce a delay of 1 msec.
          DCR  B                 ; Decrement B.
          JNZ         LOOP       ; If B is not zero jump to LOOP.
          HLT
```

SUBROUTINE PROGRAM:

```
Label     Mnemonics   Operand    Comments
DELAY     PUSH PSW               ; Push the program status word to
                                   stack.
          PUSH B                 ; Push the contents of B-C reg pair
                                   to stack.
          LXI  D,     XXXX H     ; Loads DE register pair with a 16-
                                   bit number to introduce a delay of
                                   1msec.
LOOP      DCX  D                 ; Decrements DE register pair by 1.
          MOV  A,     E          ; Moves the contents of E register to
                                   accumulator.
          ORA  D                 ; ORing of the contents of D and E
                                   registers are performed to set the
                                   zero flag.
```

	JNZ	LOOP	; If result is not zero than jump to LOOP1.
	POP B		; Pop the contents from stack to B-C reg pair back.
	POP PSW		; Pop program status word from stack.
	RET		; Go back to main program.

Example 8.15. *Write a program in assembly language of 8085 that inputs 256 bytes of data from port B of 8255A PPI with a time delay of 1msec to each input and store these bytes of data at memory locations starting at 2500 H.*

Solution. The program to implement the above is given as:

Label	**Mnemonics**	**Operand**	**Comments**
	LXI SP,	XXXX H	; Initialize stack pointer.
	MVI A,	82 H	; Initialize 8255-I to work port B as input port and ports A and C as as output ports.
	OUT	03 H	; Write the control word in the control word register of 8255-I.
	LXI H,	2500 H	; Initialize H-L reg pair with first address of destination location.
	MVI C,	FF H	; Load FF H to C reg. as pointer.
LOOP	IN	01 H	; Input from port B.
	MOV M,	A	; Load the accumulator content to memory location.
	CALL	DELAY	; Jump to delay subroutine - to introduce a delay of 1 msec.
	INX H		; Increment H-L pair.
	DCR C		; Decrement C.
	JNZ	LOOP	; If C is not zero jump to LOOP.
	HLT		

SUBROUTINE PROGRAM:

The delay subroutine program is the same as given in the previous example.

Example 8.16. *Suppose 4096 bytes of data are stored in 2000 H to 2FFF H memory locations. Write a program in assembly language of 8085 that outputs these bytes of data to port A of 8255A PPI with a time delay of 1msec to each output.*

Solution. The program to implement the above is given as:

Label	**Mnemonics**	**Operand**	**Comments**
	LXI SP,	XXXX H	; Initialize stack pointer.
	MVI A,	80 H	; Initialize 8255-I to work all the ports as output ports.
	OUT	03 H	; Write the control word in the control word register of 8255-I.
	LXI H,	19FF H	; Initialize H-L reg pair as pointer.

```
        INX  H                  ; Increment H-L reg. pair.
        MOV  A,     M           ; Load the data to accumulator.
LOOP    OUT         00 H        ; Output the data to port A.
        CALL        DELAY       ; Jump to delay subroutine - to
                                  introduce a delay of 1 msec.
        CPI         2F H        ; Compare accumulator contents to
                                  2F H.
        JNZ         LOOP        ; If not zero jump to LOOP.
        MOV  A,     L           ; Load L-reg data to accumulator.
        CPI         FF H        ; Compare with FF H.
        JNZ         LOOP        ; If not zero jump to LOOP.
        HLT
```

SUBROUTINE PROGRAM:

The delay subroutine program is the same as given in example 8.14.

Example 8.17. *A peripheral device is sending serial data to D_7 bit of port B of 8255A at an interval of 1msec. Write a program in assembly language of 8085 that converts 8 bit serial data stream to 8 bit parallel word, which is then sent to port A of 8255A.*

Solution. The program to implement the above is given as:

Label	**Mnemonics**	**Operand**	**Comments**
	LXI SP,	XXXX H	; Initialize stack pointer.
	MVI A,	82 H	; Initialize 8255-I to work port B as input port and ports A and C as output ports.
	OUT	03 H	; Write the control word in the control word register of 8255-I.
	MVI B,	00 H	; Store 00 H in register B.
	MVI C,	07 H	; Store 07 H in register C as counter.
	IN	01 H	; Inputs a byte through port B.
	ORA	B	; ORing for taking 7^{th} bit.
	RAR		; Change the position.
	MOV B,	A	; Store to B register.
	CALL	DELAY	; Jump to delay subroutine - to introduce a delay of 1 msec.
	DCR C		; Decrement C.
	JNZ	LOOP	; If not zero jump to LOOP.
	OUT	00 H	; Outputs the data to port A.
	HLT		

SUBROUTINE PROGRAM:

The delay subroutine program is the same as given in example 8.14.

Example 8.18. *Suppose 256 bytes of data are stored in the memory locations 2000 H to 20FF H. Write a program in assembly language of 8085 that converts each of these bytes into serial data stream. The serial data stream is sent (bit by bit) through D_0 bit of port A of 8255A at the rate of approximately 1000 Bits/sec. (i.e. 1msec time interval between two bits).*

Solution. The program to implement the above is given as:

Label	Mnemonics	Operand	Comments
	LXI SP,	XXXX H	; Initialize stack pointer.
	MVI A,	80 H	; Initialize 8255-I to work all the ports as output ports.
	OUT	03 H	; Write the control word in the control word register of 8255-I.
	LXI H,	1FFF H	; Initialize the H-L register pair.
LOOP	INX H		; Increment the H-L register pair.
	MOV A,	M	; Store the byte in accumulator.
	MVI B,	00 H	; Store 00 H in register B.
AGAIN	OUT	00 H	; Outputs the bit through D_0 bit of port A.
	CALL	DELAY	; Jump to delay subroutine - to introduce a delay of 1 msec.
	RAR		; Rotate right for the next bit.
	DCR B		; Decrement B.
	JNZ	AGAIN	; If not zero jump to AGAIN.
	MOV A,	L	; Move the contents of L reg. to accumulator.
	CPI	FF H	; Compare with FF H
	JNZ	LOOP	; If not equal jump to LOOP.
	HLT		

SUBROUTINE PROGRAM:

The delay subroutine program is the same as given in example 8.14.

Example 8.19. *Write a program in assembly language of 8085 that inputs a byte from port A of 8255A and determines if the decimal equivalent of the byte is even or odd. If byte is even, then send ASCII E (45 H) to port B and send ASCII O (4F H) to port B if the byte is odd.*

Solution. The program to implement the above is given as:

Label	Mnemonics	Operand	Comments
	MVI A,	90 H	; Initialize 8255-I to work port A as input port and ports B and C as output ports.
	OUT	03 H	; Write the control word in the control word register of 8255-I.
	IN	00 H	; Inputs the byte through port A.
	ANI	01 H	; ANDed with 01 H to check D_0 bit of the Byte.
	JNZ	ODD	; If not zero (odd byte) jump to ODD.
	MVI A,	45 H	; Load accumulator for ASCII E.
	JMP	END	; Jump to END.
ODD	MVI A,	4F H	; Load accumulator for ASCII O.

END	OUT	01 H	; Output ASCII E or ASCII O to port B.
	HLT		

Example 8.20. *Write a program in assembly language of 8085 that inputs a byte from port A of 8255A and determines if the decimal equivalent of the byte is even or odd. If byte is even, then send ASCII E (45 H) to D_0 bit of port B in serial fashion; if odd send ASCII O (4F H) to D_0 bit of port B in serial fashion. The time interval between two consecutive bits should be 1msec.*

Solution. The program to implement the above is given as:

Label	**Mnemonics**	**Operand**	**Comments**
	MVI A,	90 H	; Initialize 8255-I to work port A as input port and ports B and C as output ports.
	OUT	03 H	; Write the control word in the control word register of 8255-I.
	IN	00 H	; Inputs the byte through port A.
	ANI	01 H	; ANDed with 01 H to check D_0 bit of the Byte.
	JNZ	ODD	; If not zero (odd byte) jump to ODD.
	MVI A,	45 H	; Load accumulator for ASCII E.
	JMP	END	; Jump to END.
ODD	MVI A,	4F H	; Load accumulator for ASCII O.
END	MVI C,	08 H	; Store 08 H to C register.
REPEAT	OUT	01 H	; Output ASCII E or ASCII O to D0 bit of port B.
	CALL	DELAY	; Call Delay subroutine to introduce a time delay of 1msec.
	RAR		; Rotate right.
	DCR C		; Decrement C.
	JNZ	REPEAT	; If not zero jump to REPEAT.
	HLT		

SUBROUTINE PROGRAM:

The delay subroutine program is the same as given in example 8.14.

PROBLEMS

1. Using the functional block diagram of 8255A PPI, explain its detail.
2. Mention various modes of operations of 8255A PPI; explain its working in simple I/O mode.
3. Draw the schematic block diagram of 8255A and explain the function of each block.
4. Mention various modes of operations of 8255A and explain it working in BSR mode. Explain also its control word format.

5. Draw and explain the control word format of 8255A. What will be control word if 8255 is used in simple I/O mode with port A as input port, port B as output port and port C_{Lower} as input port and Port C_{Upper} as output port?
6. Discuss the mode 1 output configuration of 8255. Discuss also its control word, control signals, timing diagram and status word.
7. Discuss the mode 1 Input configuration of 8255. Discuss also its control word, control signals, timing diagram and status word.
8. Explain how 8255 can be used in mode 2. Give the format of the control word when port A is used to operate in mode 2 and port B is operated in mode 1.
9. Give the format of the control word when port A is used to operate in mode 2 and port B is operated in mode 0. Port C_{Lower} is used as simple input or output.
10. Write an assembly language program of 8085A to output the contents of B-register to port A of 8255 A PPI.
11. Eight LEDs are connected to port B of 8255 A. write an assembly language program of 8085 to glow LEDs 0, 2, 4, 6 for 1 sec and then glow LEDs 1, 3, 5, 7 for the same time and repeat.
12. Obtain the control word when the ports of 8255A are to be used in mode 0 with port A as input port, port B as output port, and port C_{Lower} as output port and port C_{upper} as input port.

(Ans. 98 H)

13. Make a control word when the ports of 8255 A are to be used in mode 0 with all the ports as input ports.

(Ans. 9B H)

14. Obtain the control word for the following configuration of the ports of 8255 A for Mode 0 operation:
    Port A and port B as output ports and port C_{Lower} as output port; and port C_{upper} as input port.

(Ans. 88 H)

15. Obtain the control word for the following configuration of the ports of 8255 A for mode 1 operation:
    Port A – as input port,
    Mode for Port A – mode 1
    Port B – input port
    Mode for Port B – mode 1,
    The remaining pins of port C_{Upper} are to be used input pins.

(Ans. BE H or BF H)

15. Obtain the control word for the following configuration of the ports of 8255 A for mode 1 operation:
    Port A – output port in mode 1,
    Port B – output port in mode 1,
    The remaining pins PC_4 and PC_5 of port C are to be used output pins.

(Ans. A4 H or A5 H)

16. Obtain the control word for the following configuration of the ports of 8255 A:
    Port A – as bidirectional,
    Mode for Port A – mode 2
    Port B – input port,

Mode for Port B – mode 0,
Port C_{Lower} –output port.

(Ans. C2 H)

17. Write an assembly language program of 8085A to generate square wave of 100 Hz frequency using 8255A PPI. The wave should be available at PB_0 terminal of port B. Give the program of delay subroutine also.
18. Generate square wave of 100 Hz using BSR mode of 8255A. The wave should be available at PC4 terminal (D_4 bit of port C).
19. Write a program in 8085 assembly language to blink an LED at a regular interval of time. Assume LED is connected to PA_0 (D_0 bit of port A of 8255A PPI).
20. Write a program in 8085 assembly language to blink an LED at a regular interval of time using Bit Set/Reset (BSR) mode. Assume LED is connected to PC_0 (D_0 bit of port C of 8255A PPI).

Programmable Interval Timer/Counter: 8253

In many industrial applications precise time delays are needed. In discrete systems the time delays are generated using electronic timer based on logic gates and circuits or mechanical timers. However, in microprocessor based systems the time delays can be generated using software. The generation of accurate time delays by software control is very commonly used method as discussed in the earlier chapters of this book. In this method the processor has to wait for some time to generate a time delay, as microprocessor becomes unnecessarily busy in looping. The programmable interval timer/counter chip 8253 solves this problem. It is one of the most supporting chips for 8085 microprocessor. It is used for teal time applications. It can generate accurate time delays and wave forms using the software control. This chip includes three identical 16-bit pre-settable down counters that can operate independently, as each counter has a clock input, gate input and one output. The counters can count in binary or BCD. In this chapter a detailed discussion on this chip and its applications will be carried out.

9.1 INTEL PROGRAMMABLE INTERVAL TIMER 8253

Intel 8253 Programmable Interval Timer/Counter is an NMOS 24 pin plastic dual in line package (DIP). It operates at +5 volt d.c. source. It can generate accurate time delays and wave forms using the software control. This chip includes three identical 16-bit pre-settable down counters that can operate independently; namely counter 0, counter 1 and counter 2. The counters can count in binary or BCD. Each counter has a clock input, gate input and one output. The gate input enables the counting process. The counting may be started by applying the gate signal. The 8253 works at maximum clock frequency of 2 MHz. There is another programmable interval time which is upgraded version of 8253. It has pin compatible and software compatible with 8253. The 8254 can operate with high clock frequency up to about 8 MHz. This chip 8254 is compatible to 8086, 8088 and other microprocessors. However, 8253 is compatible to 8085microprocessor. We shall discuss the details of the chip 8253.

The 8253 can operate on the following six modes:

Mode 0: Interrupt on Terminal Count
Mode 1: Programmable one shot
Mode 2: Rate Generator
Mode 3: Square Wave Generator
Mode 4: Software Triggered Mode
Mode 5: Hardware Triggered Mode

The three counters of this chip can operate independently in any of the six modes.

9.2 BLOCK DIAGRAM OF 8253

Figures 9.1 and 9.2 show the pin diagram and functional block diagram of 8253. It has a data bus to be connected to the data bus of the microprocessor, a control word register, five control signals and three 16-bit presettable down counters namely:

Counter 0
Counter 1
Counter 2.

Control word Register:

The control word register of 8253 is accessed when A_0 and A_1 terminals are at logic 1. It is used to write a command word which specifies the counter to be used, its mode, and either Read or Write operation,

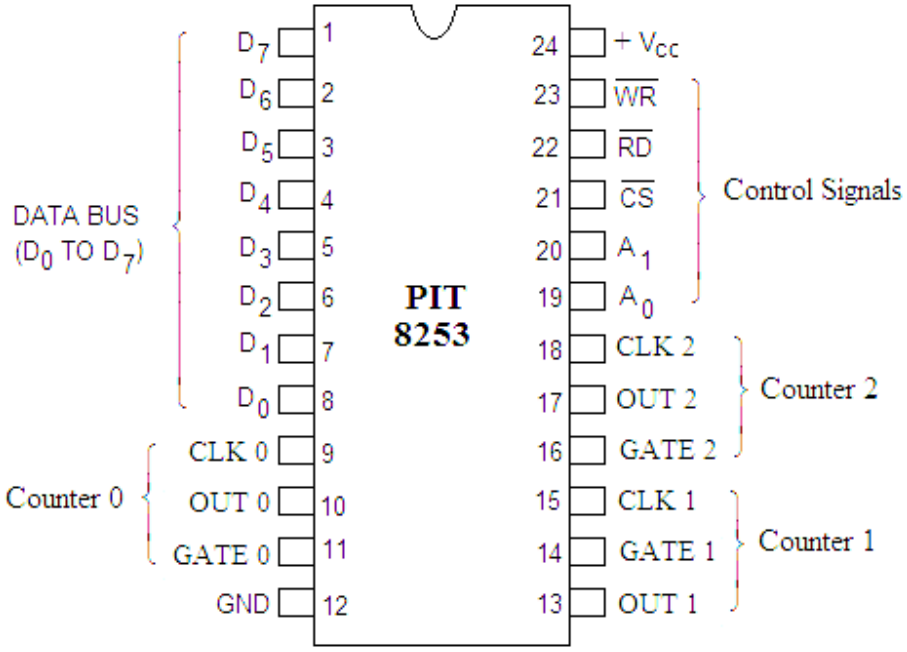

Fig. 9.1

The description of pins of 8253 Programmable Interval Timer (PIT) is given as follows:

Pin Nos. 1-8: form the bidirectional data bus buffer (D_7 to D_0) to be connected to the control bus of the microprocessor.

Pin Nos. 9-11: are provided for counter 0. Pin 9 is CLK 0 (Clock input terminal for counter 0), Pin 10 is OUT 0 (Output terminal for counter 0) and Pin 11 is GATE 0 (Gate input terminal for counter 0).

Pin No. 12: is the ground terminal.

Pin Nos. 13-15 are allotted to counter 1. Pin 13 is OUT 1 (Output terminal for counter 1), Pin 14 is GATE 1 (Gate input terminal for counter 1) and pin 15 is CLK1 (Clock input for counter 1).

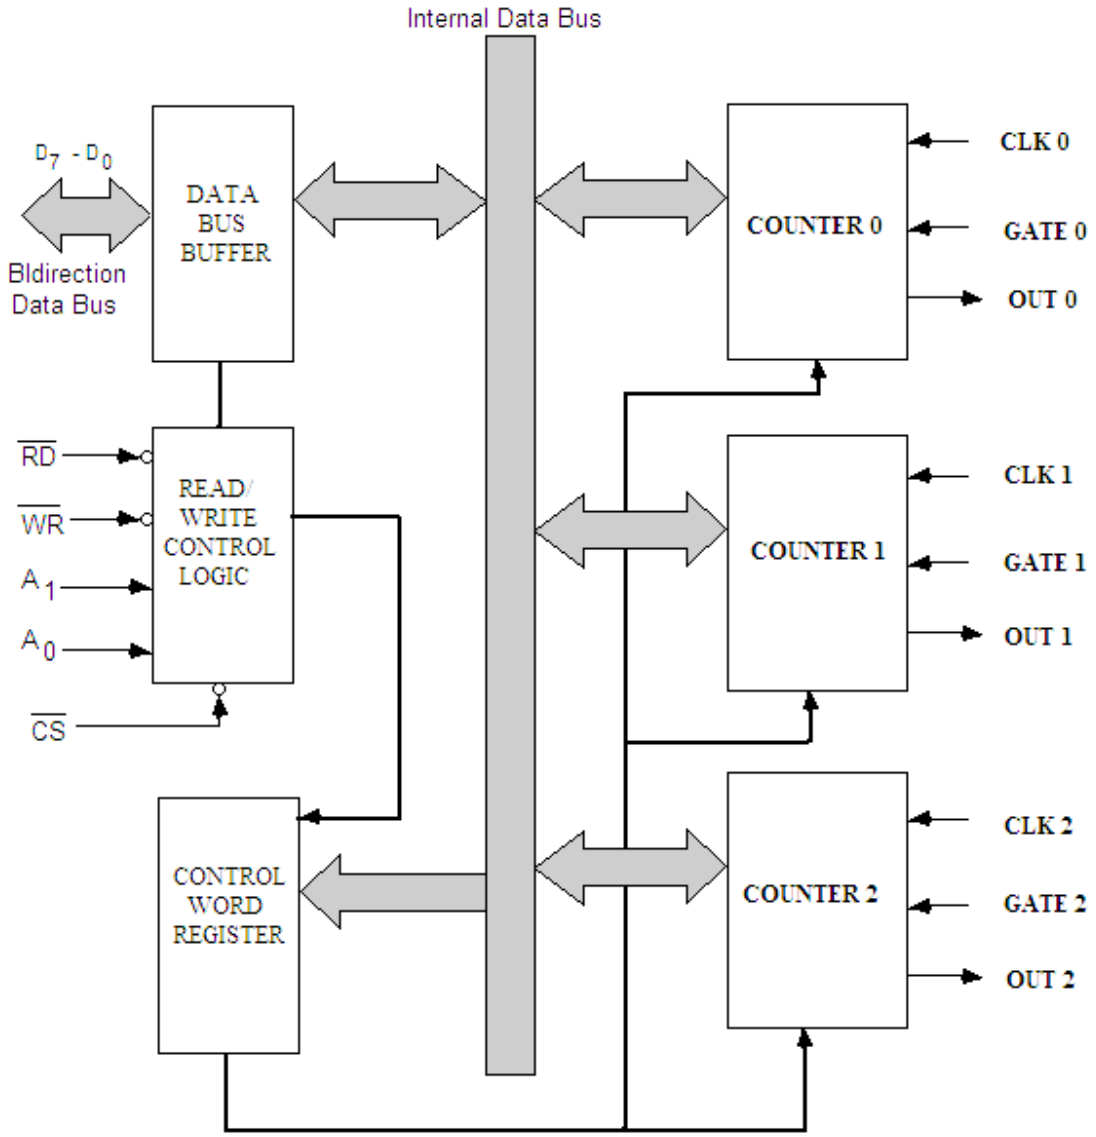

Fig. 9.2

Pin Nos. 16-18 are for counter 2. Pin 16 is GATE 2 (Gate input terminal for counter 2), Pin 17 is OUT 2 (Output terminal for counter 2) and pin 18 is CLK 2 (Clock input for counter 2).

Pin Nos. 19-20 are A_0 and A_1 terminals respectively. These terminals are used to select any one of the three counters and the control word register of 8253. These lines are to be connected to the address bus.
The counters and control word register are selected as given in table 9.1.

Table 9.1

A_0	A_1	Selection for Counters
0	0	Counter 0 is selected.
0	1	Counter 1 is selected.
1	0	Counter 2 is selected.
1	1	Counter 3 is selected.

Pin No. 21 is $\overline{CS}$ (Chip select terminal). It is an active low signal which allows enabling the device.

Pin No. 22 is $\overline{RD}$ (Read terminal). It is also an active low signal. A low to this pin informs the 8253; that the CPU is ready to receive the data in the form of count value.

Pin No. 23 is $\overline{WR}$ (Write terminal). When this pin is low, the microprocessor outputs data in the form of mode operation or loading of counter.

Pin No. 24 is + V_{CC} (+5 V) terminal.

9.3 LOGICS FOR COUNTERS

As already discussed, the 8253 has five control signals $\overline{CS}$, $\overline{RD}$, $\overline{WR}$, A_1 and A_0. The table 9.2 shows the action of different combination of these control signals.

Table 9.2

$\overline{CS}$	$\overline{RD}$	$\overline{WR}$	A_1	A_0	Actions
0	1	0	0	0	Load counter 0
0	1	0	0	1	Load counter 1
0	1	0	1	0	Load counter 2
0	1	0	1	1	Write Mode Word
0	0	1	0	0	Read counter 0
0	0	1	0	1	Read counter 1
0	0	1	1	0	Read counter 2
0	0	1	1	1	No operation 3 state
0	1	1	X	X	No operation 3-state
1	X	X	X	X	Disable 3-state

Note: X indicates undefined state, i.e. it does not matter whether it is 0 or 1.

From this table it is clear that when $\overline{CS} = \overline{WR} = 0$ and $\overline{RD} = 1$ with different combination of A_1 and A_0; any counter can be selected and loaded with 16 counter values. Once the gate is enabled by applying a high signal (logic 1) to it, counter values starts decrementing at each of the trailing edge of the clock pulse. However, if $\overline{CS} = \overline{RD} = 0$ and $\overline{WR} = 1$, the counter read operation is performed by the different counters.

The clock pulse is to be applied to CLK terminal of each counter of 8253. Though the clock signal of 3 MHz frequency is available with 8085 microprocessor but it can not directly be applied to the CLK terminal of each counter. Since 8253 can work with a maximum of 2 MHz clock frequency. So the clock frequency available with 8085 microprocessor is divided by a factor of 2 using an edge triggered D-flip flop (7474) as shown in figure 9.3. So 1.5 MHz clock frequency available at the output of D-flip flop can be used as CLK input of the counters of 8253. In some microprocessor kits available in the market for use in laboratories, the CLK terminals of the counters are left open so that any clock signal of desired frequency may be connected to these terminals.

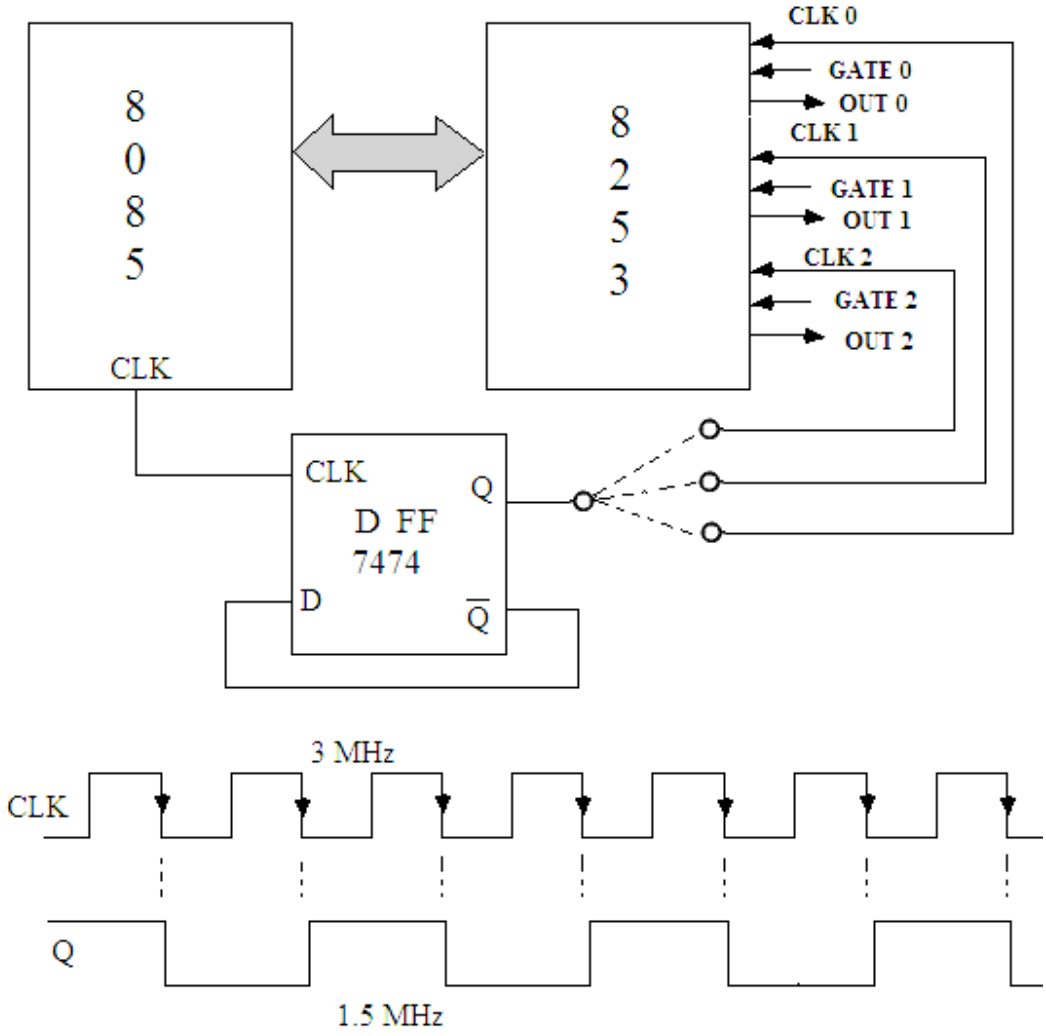

Fig. 9.3

9.4 CONTROL WORD FORMAT OF 8253

As already discussed, any of the three counters can be programmed to operate in any of the 6 modes. The control word decides the selection of counter, its mode of operation, loading, sequence of the count and selection of binary or BCD counting. The format for the control word of 8253 is shown in figure 9.4. The control word is written into the control word register of 8253, as per the requirement.

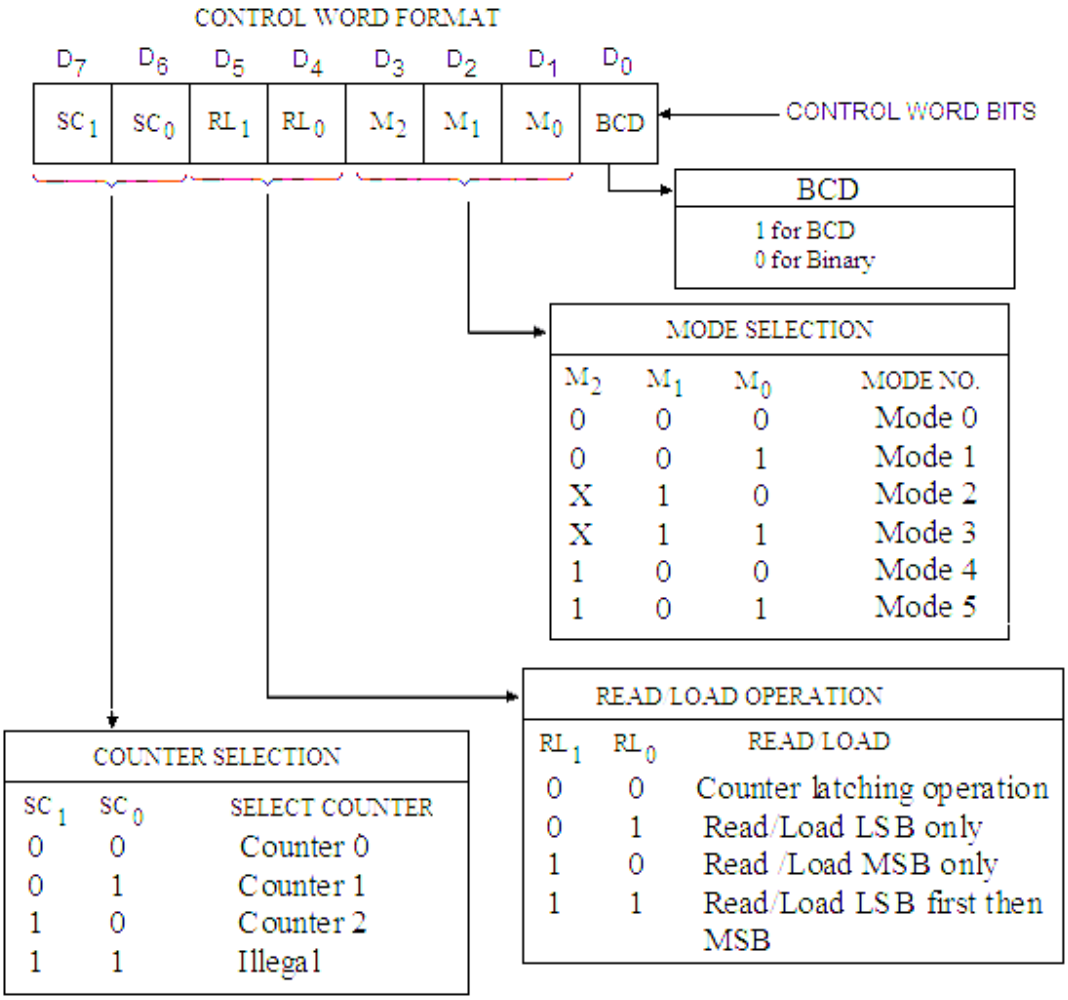

Fig. 9.4

The description of the bits of control word format is given as:

Bit D_0 Sets the counting of the counter in binary or BCD. To make the counting in BCD this bit is set to 1, and to make the counting in binary this bit is set to 0.

Bits D_1-D_3 These three bits are called mode selection bits M_0, M_1 and M_2 respectively; and are used for mode selection of the counters which are given in table 9.3.

Table 9.3

D_3 (M_2)	D_2 (M_1)	D_1 (M_0)	Mode
0	0	0	Mode 0
0	0	1	Mode 1
X	1	0	Mode 2
X	1	1	Mode 3
1	0	0	Mode 4
1	0	1	Mode 5

Bits D_4-D_5 These bits are known as Read/Load bits (RL_0 and RL_1) and are used for read/load of the count values in the counters. Their operations are given in table 9.4.

Table 9.4

D_5 (RL_1)	D_4 (RL_0)	Mode
0	0	Counter latching operation
0	1	Read/Load LSB only
1	0	Read /Load MSB only
1	1	Read/Load LSB first then MSB

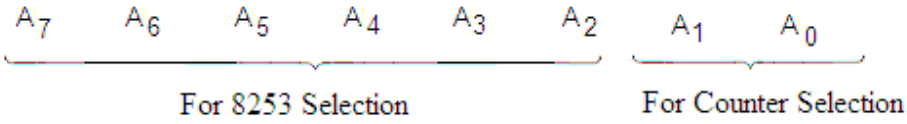
Bits D_6-D_7 These bits (SC_0 and SC_1) are used for counter selection as given in table 9.5.

Table 9.5

D_7 (SC_1)	D_6 (SC_0)	Select counter
0	0	Counter 0
0	1	Counter 1
1	0	Counter 2
1	1	Illegal

9.5 INTERFACING AND PROGRAMMING OF 8253

Figure 9.5 shows interfacing of 8253 with the 8085 system bus. The eight data lines D_0 to D_7 of 8253 are connected to the data bus (Address data bus AD_0-AD_7) of the microprocessor. The chip is selected with $\overline{CS}$ terminal. So higher order address bus of the system is used for decoder circuit to select the chip. The A_8 and A_9 (two LSBs of the address bus) terminals of the microprocessor address bus are connected to A_0 and A_1 terminals of 8253 to select the proper counter. i.e.



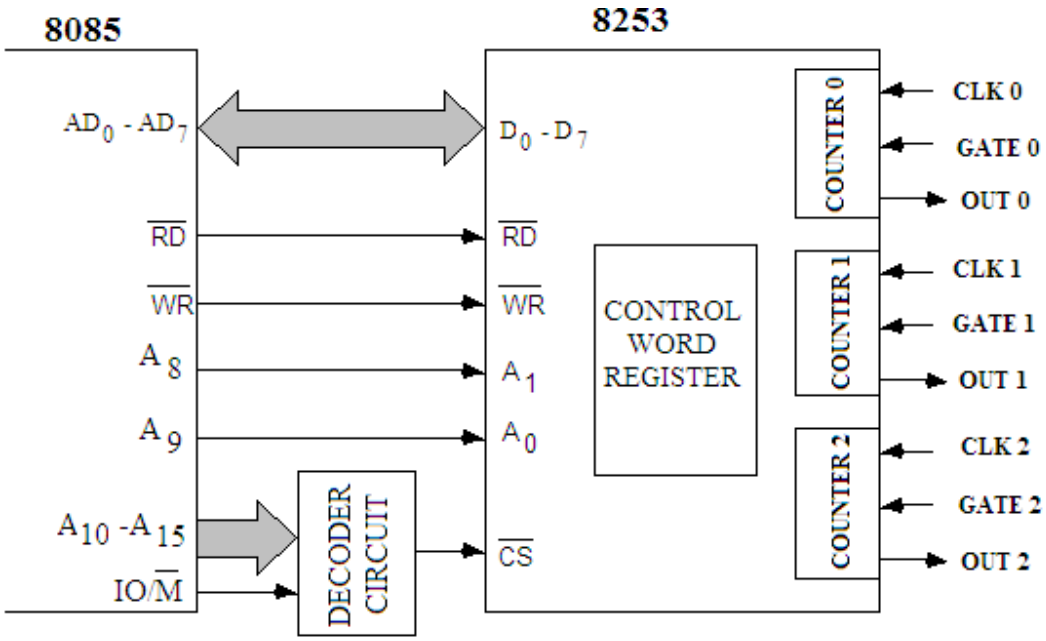


Fig. 9.5

Figure 9.6 shows the chip-select logic for 8253. From this logic diagram it is clear that if $A_2 – A_3$, $A_5 – A_7$ are all at logic 0 and A_3 is at logic 1, then it enables $\overline{CS}$ to select this chip. The counter selection will depend on the bits $A_1 – A_0$ as shown in table 9.6.

Table 9. 6

$\overline{CS}$									
A_7	**A_6**	**A_5**	**A_4**	**A_3**	**A_2**	**A_1**	**A_0**	**HEX ADDRESS**	**Counter Selection**
0	0	0	1	0	0	0	0	10 H	Counter 0
0	0	0	1	0	0	0	1	11 H	Counter 1
0	0	0	1	0	0	1	0	12 H	Counter 2
0	0	0	1	0	0	1	1	13 H	Control word Register

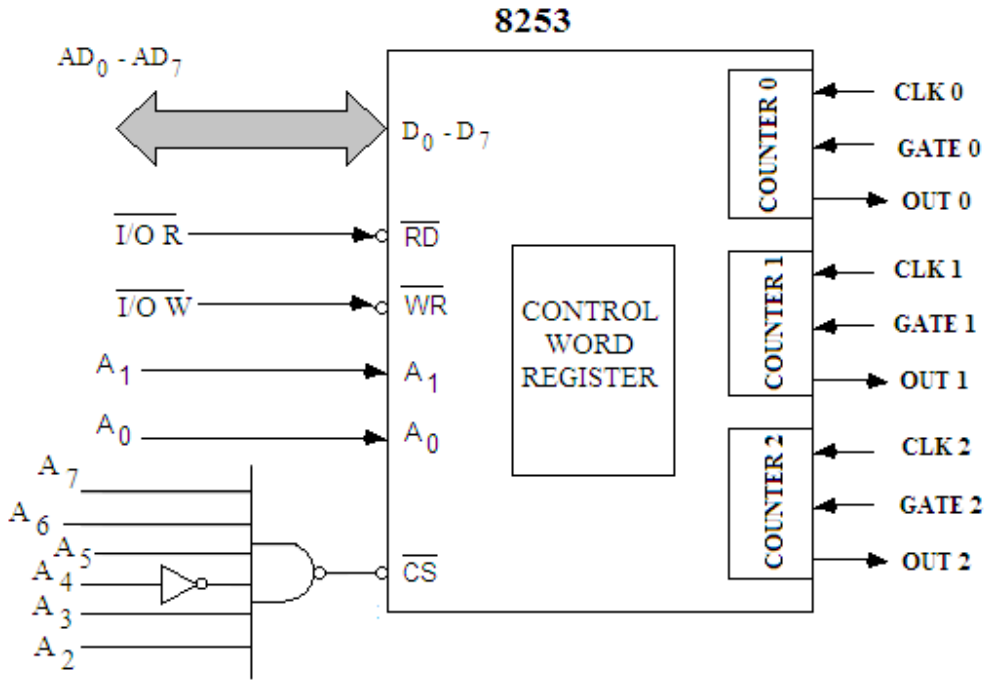

Fig. 9.6

As usual with IN and OUT instructions, the 8085 duplicates the port address on the address bus and data bus. The OUT instruction loads the control word in the control word register. As discussed above we may choose the hexadecimal address as

10 H	for counter 0
11 H	for counter 1
12 H	for counter 2
13 H	for control word register (CWR).

The OUT 13 H will load the accumulator content to the control word register. The accumulator is therefore, to be loaded to the proper control word (as decided by the control word format) before OUT 13 H instruction. This way 8253 is initialized. To load the count values to the counter number initialized by the OUT 13 instruction, again OUT instruction is used having the proper control word.

The IN instruction with proper port address will read the count values of the counter without stopping the counting. The 8253 can thus be programmed through write operations to generate various types of wave forms (which will be discussed in the succeeding section of this chapter) by loading the proper count values to any of the counters used in different modes.

So for programming the 8253 we proceed as given in the flow chart (figure 9.7).

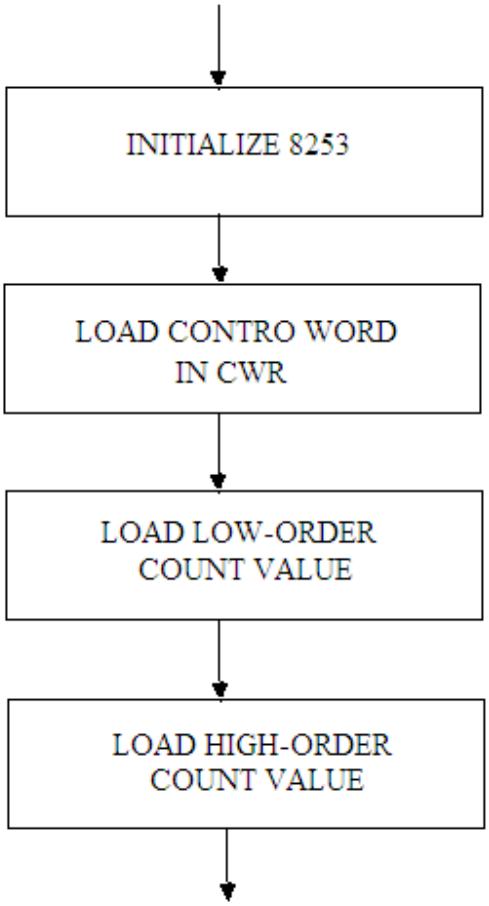

Fig. 9.7

For example to load counter 0 in mode 0 for the count value 1639 H in binary, we follow the program given below. The control word, to initialize the 8253 to load the given count value, first LS byte and then MS byte to the counter 0 in mode 0, is shown in figure 9.8.

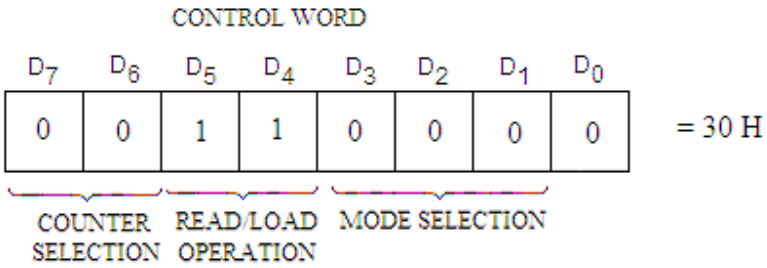

Fig. 9.8

Program:

Label	**Mnemonics**	**Operand**	**Comments**
	MVI A,	30 H	; Accumulator is loaded with the control word 30 H to Initialize 8253.

```
OUT        13 H      ; Write the control word in the
                       control word register of 8253.
MVI  A,    39 H      ; Load accumulator with LS byte
                       (39) of the count value.
OUT        10 H      ; First LS byte of the count value is
                       loaded to the counter 0 of 8253.
MVI  A,    16 H      ; Load accumulator with MS byte
                       (16) of the count value.
OUT        10 H      ; MS byte of the count value is then
                       loaded to the counter 0 of 8253.
. . . . . .
. . . . . .
. . . . . .
```

The count value of any counter of 8253 can also be read without stopping the counting. The bit pattern for the control word (figure 9.9) for latching operation is as follows:

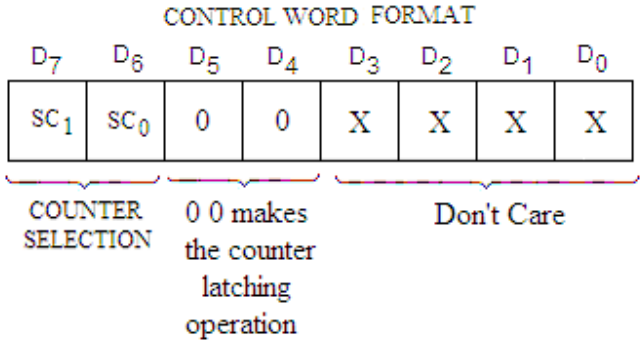

Fig. 9.9

The control word for latching operation for counter 0 is 00 H as shown in figure 9.10.

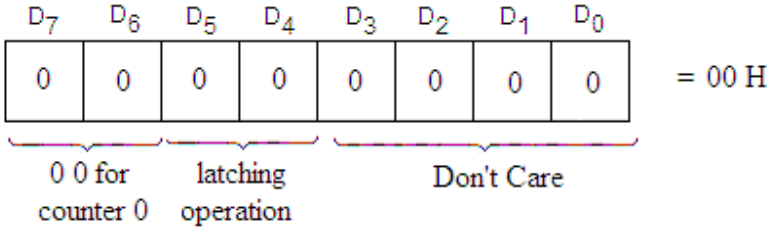

Fig. 9.10

So the following program can be used to read the count value of counter 0 while counting is in program.

Program:

```
Label      Mnemonics   Operand     Comments
           MVI  A,     00 H      ; Control word 00 H to read the
                                   count value of the counter 0 is
                                   loaded to accumulator.
           OUT         13 H      ; The control word is loaded in the
                                   control word register of 8253.
```

```
IN        10 H    ; First read the LS byte of the count
                    value.
MOV  B,   A       ; Load this value to B-register.
IN        10 H    ; Read the MS byte of the count
                    value.
MOV  C,   A       ; Load this value in C-register.
MVI  A,   16 H    ; Load accumulator with MS byte of
                    the count value.
. . . . . .
. . . . . .
```

Example 9.1. *Initialize 8253 to load counter 1 in mode 0 with 8bit binary number 06 H.*
Solution. To initialize 8253 we have the control word as (Figure 9.11):

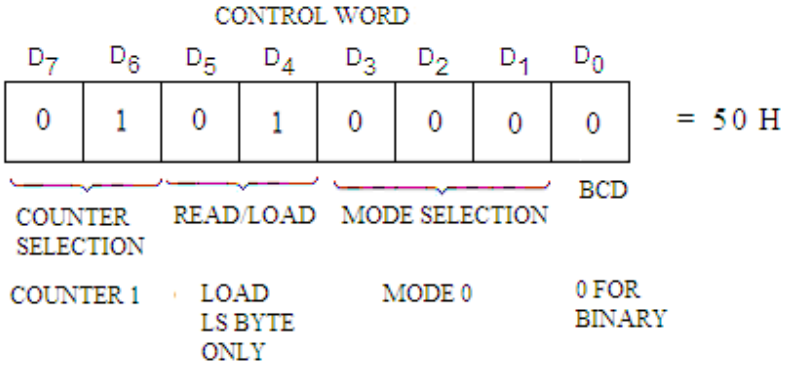

Fig. 9.11

The program for the same is written as:

Program:

Label	Mnemonics	Operand	Comments
	MVI A,	50 H	; Accumulator is loaded with the control word 50 H to Initialize 8253.
	OUT	13 H	; Write the control word in the control word register of 8253.
	MVI A,	06 H	; Load accumulator with LS byte (06 H) only of the count value.
	OUT	11 H	; 06 H of the count value is loaded to the counter 1 of 8253.
	HLT		; Stop processing.

Example 9.2. *Initialize 8253 to load counter 0 in mode 1 with 1632 H BCD number.*
Solution. To initialize 8253 we have the control word as (Figure 9.12):

The program for the same is written as:

Program:

Label	Mnemonics	Operand	Comments
	MVI A,	33 H	; Accumulator is loaded with the control word 33 H to Initialize 8253.
	OUT	13 H	; Write the control word in the control word register of 8253.

```
MVI  A,     32 H     ; Load accumulator first with LS byte (32 H) of the count value 1632 H.
OUT         10 H     ; 32 H of the count value is loaded to the counter 0 of 8253.
MVI  A,     16 H     ; Load accumulator then with MS byte (16 H) of the count value.
OUT         10 H     ; 16 H of the count value is loaded to the counter 0 of 8253.
HLT                  ; Stop processing.
```

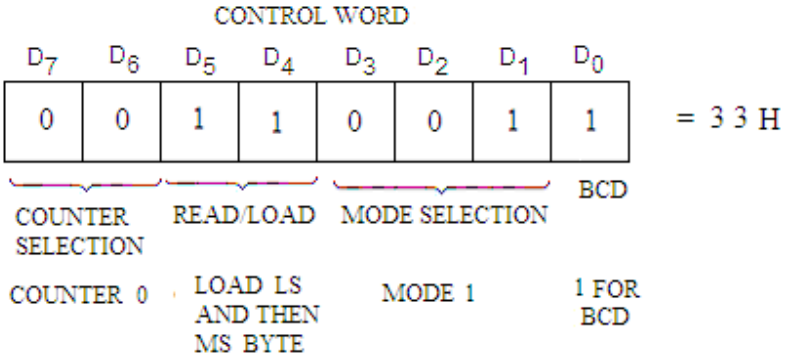

Fig. 9.12

Example 9.3. *Initialize 8253 to load counter 2 in mode 1 with a count value 5000_{10} in mode 0. Read the count value on the fly.*

Solution. To initialize 8253 we have the control word as (Figure 9.13):

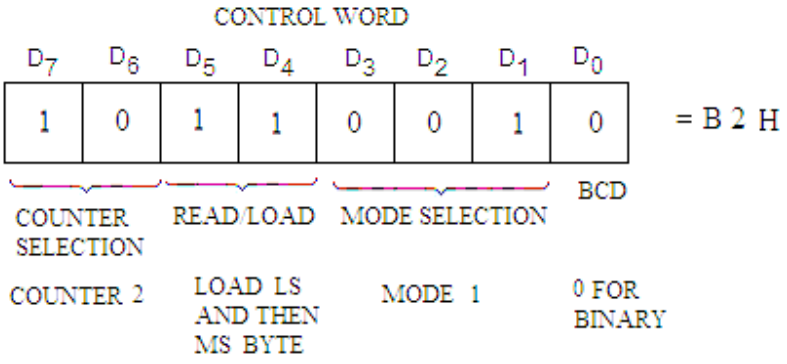

Fig. 9.13

The control word for latching operation for counter 2 is 80 H as shown in figure 9.14.

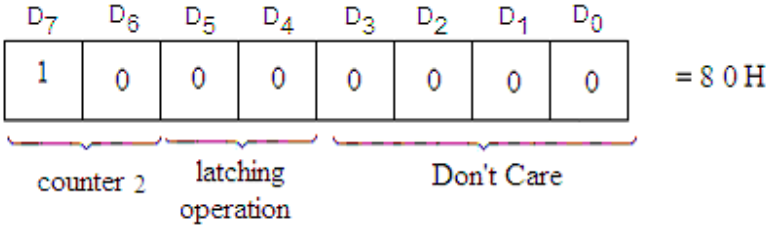

Fig. 9.14

The program for the same is written as:

The hexadecimal equivalent of 5000_{10} is 1388 H.

Program:

Label	Mnemonics	Operand	Comments
	MVI A,	B2 H	; Accumulator is loaded with the control word B2 H to Initialize 8253.
	OUT	13 H	; Write the control word in the control word register of 8253.
	MVI A,	88 H	; Load accumulator first with LS byte (88 H) of the count value 1632 H.
	OUT	12 H	; 88 H of the count value is loaded to the counter 2 of 8253.
	MVI A,	13 H	; Load accumulator then with MS byte (13 H) of the count value.
	OUT	12 H	; 16 H of the count value is loaded to the counter 2 of 8253.
	MVI D,	00 H	; Store 00 H to D-register.
LOOP	MVI A,	80 H	; Control word 80 H to read the count value of the counter 2 is loaded to accumulator.
	OUT	13 H	; The control word is loaded in the control word register of 8253.
	IN	12 H	; First read the LS byte of the count value.
	MOV B,	A	; Load this value to B-register.
	IN	12 H	; Read the MS byte of the count value.
	ORA B		; Logical OR the LS and MS byte to set zero flag.
	JNZ	LOOP	; If not zero jump to LOOP.
	HLT		; Stop processing.

9.6 PROGRAMMING OF 8253 IN MODE 0: INTERRUPT ON TERMINAL COUNT

The MODE 0 is interrupt on terminal count. The output of the desired counter goes low on setting the mode, and goes high after the loaded counts are complete. It is used for the generation of precise time delay under software control. After the selection of desired counter, a suitable count value is loaded in the counter. The GATE terminal of the selected counter is made high from low. The down counting of the counter will be started. At the beginning of the counter, OUT terminal becomes low and remains low till the counting is stopped at the zero count value. On reaching the terminal count (i.e. count value becomes zero), the OUT terminal becomes high (logic 1) and remains high until and unless the selected counter is reloaded or a new count value is loaded or the mode of operation is changed. Further, if the count value is reloaded in count register while the counting is in progress, then after LS byte of the count value is written, the current counting is stopped; and after MS byte of the count value is written, the counting restarts

with the new count value. The timing diagram for mode 0 operation is shown in figure 9.15.

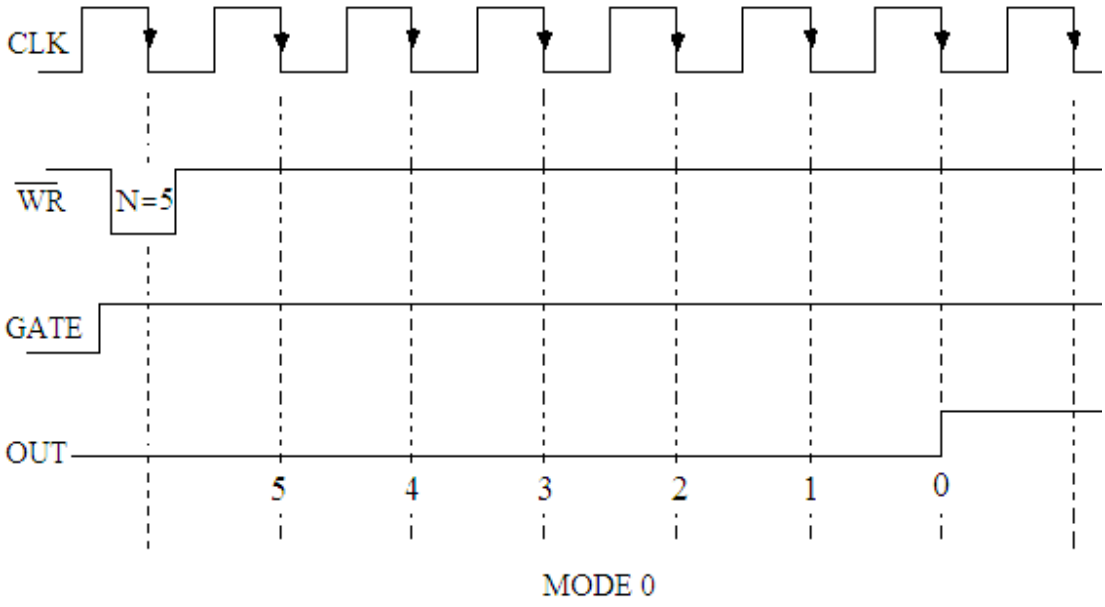

Fig. 9.15

If during the counting operation, GATE terminal is made low from high, the counting will be suspended. If the GATE terminal is again made high the counting may be resumed at the trailing edge of the clock pulse from the value where the counting was suspended. This is depicted in figure 9.16. The OUT terminal can be used to interrupt the microprocessor.

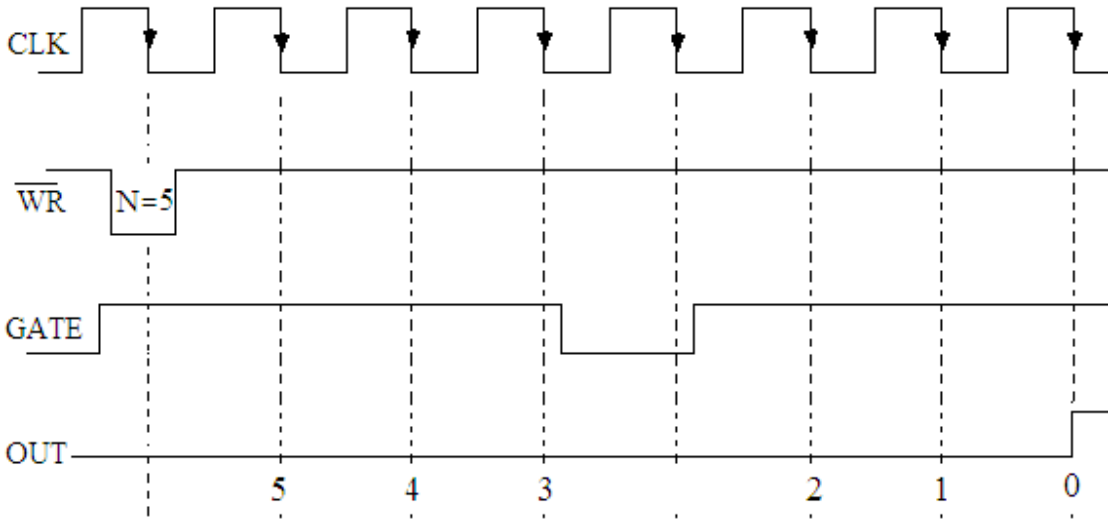

Fig. 9.16

9.7 PROGRAMMING OF 8253 IN MODE 1: PROGRAMMABLE ONE SHOT

The MODE 1 is Programmable or retriggerable one shot. In this mode the OUT terminal of the counter goes low on the triggering of corresponding GATE input (low to high transition); which (OUT terminal) goes high on terminal count. The OUT terminal remains low for the count value loaded to the counter.

Initially control word and count values are loaded to the device register. A leading edge trigger signal is applied to the GATE input of the selected counter. At the next trailing edge of the clock the OUT terminal goes low. The down counting of the counter will now start and at the terminal count (i.e. count value becomes zero) the OUT terminal becomes high. In other word we can say that the OUT terminal remains low for the number of counts loaded in the selected counter. In this mode the counter thus be used as a triggered mono (or one) shot of desired width. This width can be varied by the count value loaded for the selected counter. It is illustrated in figure 9.17. The changing signal from high to low to GATE terminal does not affect the signal of OUT terminal, once the counting is started.

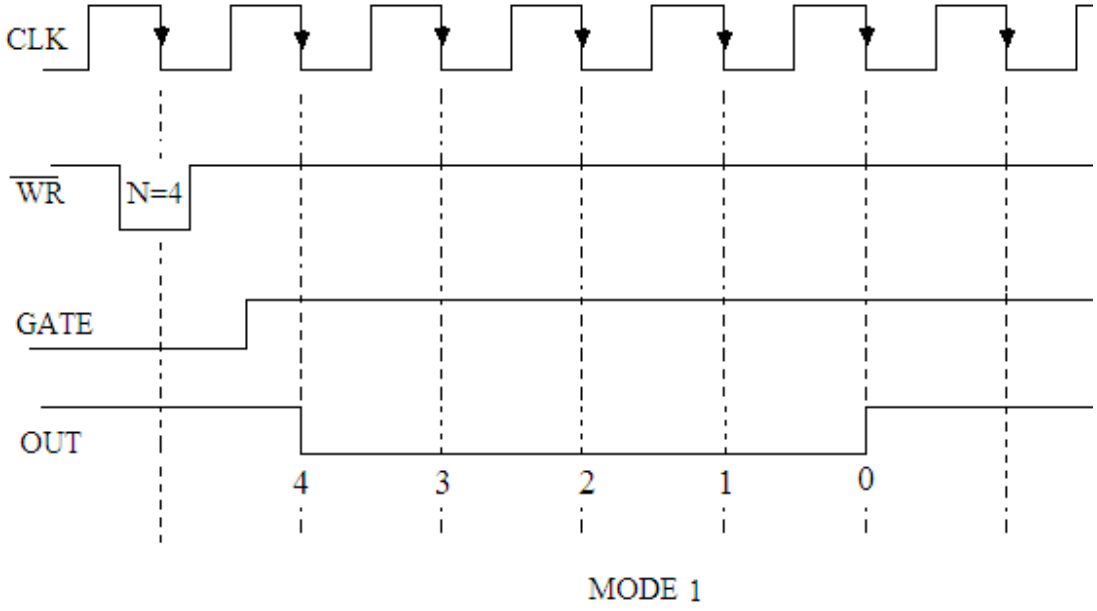

Fig. 9.17

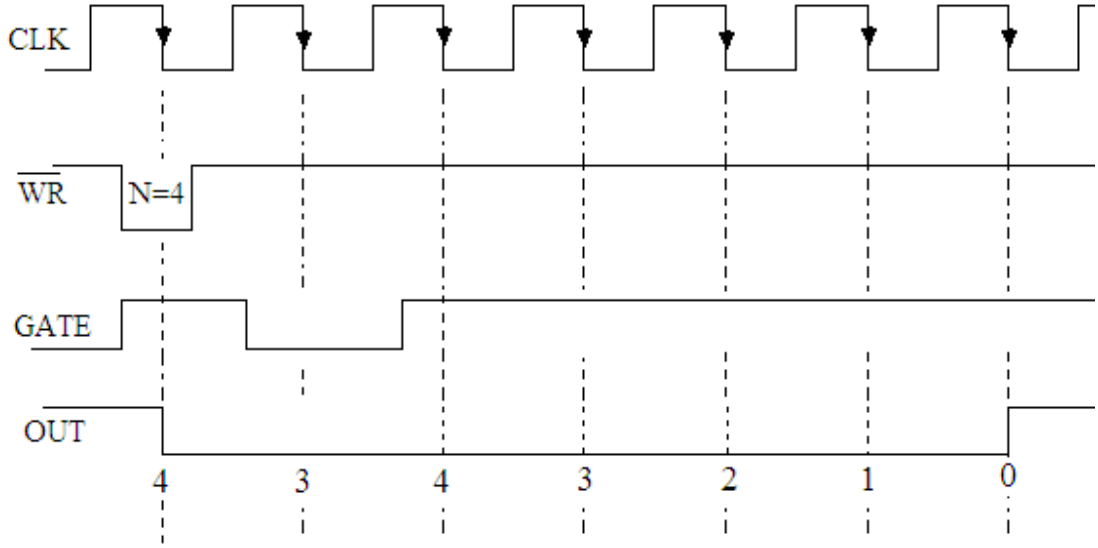

Fig. 9.18

If the signal at the GATE terminal is changed from low to high when the counting is in progress, then the counting will be stopped for exactly one clock pulse. After one

clock pulse, the recounting will be started from the beginning i.e. the counter will be reloaded with the same count value and the down counting will be started again and the OUT terminal goes low for the same count value. Thus it is also called retriggerable one shot. This situation is shown in figure 9.18.

A new count may be loaded to the counter while OUT terminal is low; it will not affect the width of the low OUT signal until the next trigger is applied to the GATE.

9.8 PROGRAMMING OF 8253 IN MODE 2: RATE GENERATOR

Any counter of 8253 may be programmed to operate in mode 2 as rate generator which is also called as divide by N counter.

Initially control word for mode 2 and count value N are loaded into the selected counter. The down counting of the counter will be started as soon as a high signal to the GATE terminal of the counter is applied. The OUT terminal stays high for (N-1) clock pulses and becomes low for exactly one clock pulse. After this OUT signal goes high again for (N-1) clock pulses and low for one pulse as the count value N is reloaded into the selected counter. This process continues as long as the GATE terminal is high. It, therefore, works as divide by N counter. Further, if the counter is working in this mode and a new count value is loaded, the present period will not be affected but the subsequent period will be as per the new count value. The timing diagram is shown in figure 9.19.

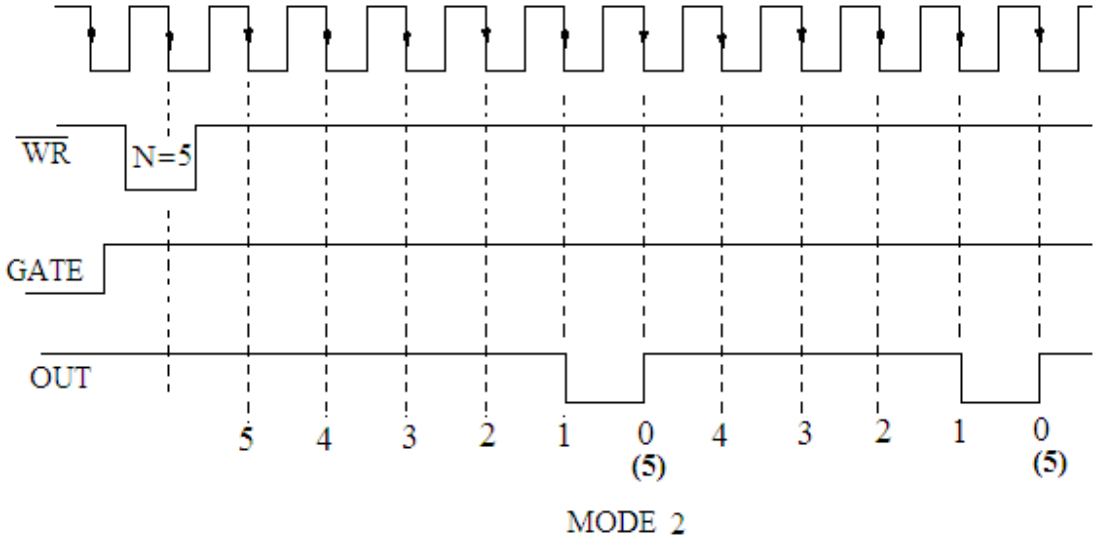

Fig. 9.19

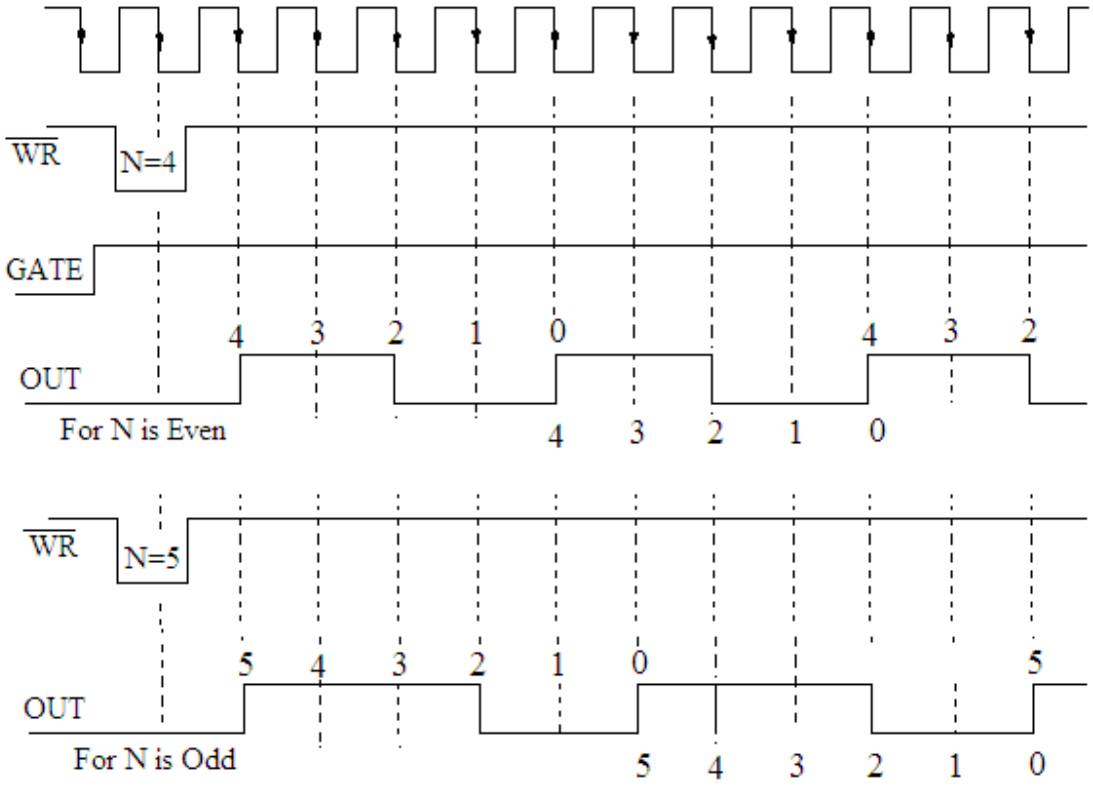
The GATE input when low, will force the OUT terminal to high. When the GATE input goes high, the counter will start from the initial count. Thus the GATE can be used to synchronize the counter.

9.9 PROGRAMMING OF 8253 IN MODE 3: SQUARE WAVE GENERATOR

When 8253 operate in mode 3, the counter acts as a square wave generator. This is similar to mode 2 with the difference that the OUT terminal of the selected counter in mode 3 remains high for half the count value and is low for the other half, if the count value is an even number. However, if the count value is an odd value, OUT terminal remains high for $\left(\frac{N+1}{2}\right)$ clock pulses and is low for $\left(\frac{N-1}{2}\right)$ clock pulses.

When control word for mode 3 and count value N are loaded into the selected counter, a high signal at the GATE terminal starts the down counting. The OUT terminal remains high for $\left(\frac{N}{2}\right)$ counts and is low for the next $\left(\frac{N}{2}\right)$ counts, if the count value N is even; and for odd value of N, the OUT signal is high for $\left(\frac{N+1}{2}\right)$ pulses and is low for $\left(\frac{N-1}{2}\right)$ pulses as mentioned above. The count value is reloaded with full count and the process is repeated till the GATE is high. Figure 9.20 shows the timing diagram for this mode of operation for both even and odd count value.



MODE 3

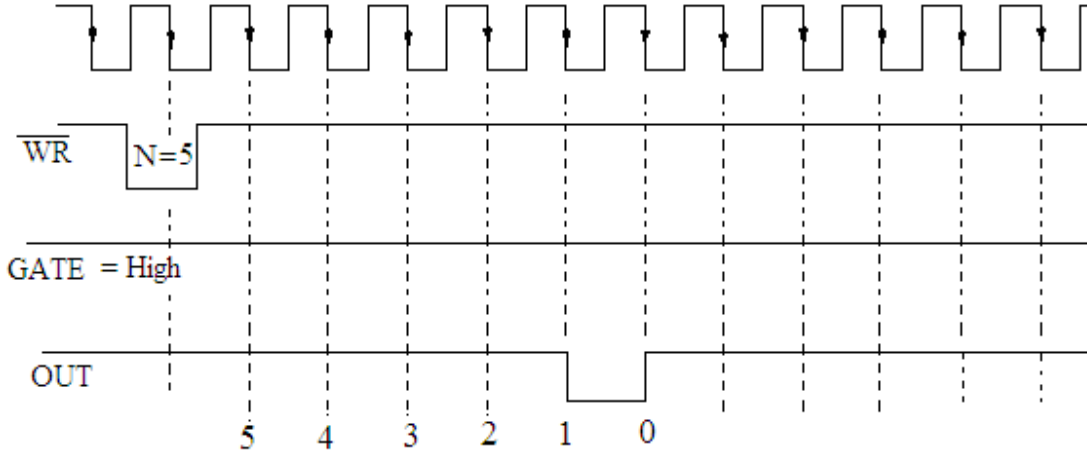
Fig. 9.20

The mode of operation of 8253 generates a square wave of period specified by the count value loaded to the counter. Any change in count value becomes effective, after the present counts are over.

9.10 PROGRAMMING OF 8253 IN MODE 4: SOFTWARE TRIGGERED STROBE

In this mode of operation software controlled delayed negative pulse of one clock period duration is generated with and without synchronization. After the mode of operation of 8253 is set, the OUT terminal will be high, and the down counting of the counter will start as soon as the count value is loaded into the counter. On terminal count,

the OUT terminal goes low for one clock pulse then will go high again as shown in figure 9.21.



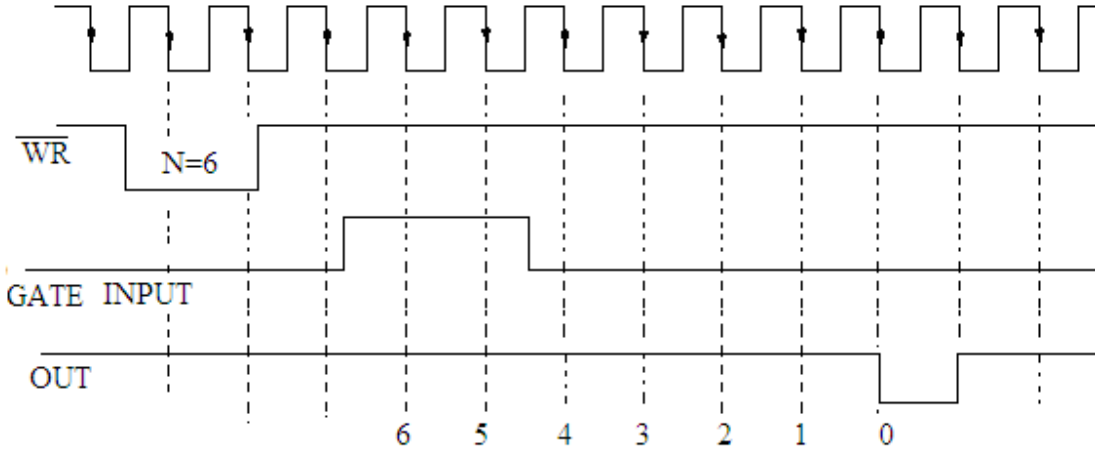
MODE 4

Fig.9.21

If the count register is reloaded between the output pulses, the present period will not be affected, but the subsequent period will reflect the new count value. The counter will be inhibited when the GATE terminal goes low. The GATE input can, therefore, be used for synchronization. The generation of strobe signal at OUT terminal is triggered by loading the count value in the counter that is why this mode is called software triggered mode.

9.11 PROGRAMMING OF 8253 IN MODE 5: HARDWARE TRIGGERED STROBE

In this mode of operation a delayed negative pulse of one clock period duration is generated if a positive going trigger input is applied at the GATE terminal. After the mode of operation of 8253 is set, and the count value is loaded into the counter OUT



MODE 5

Fig. 9.22

terminal will be initially high. As the rising edge signal is applied to GATE terminal, the down counting of the counter will be started at the first trailing edge of the clock pulse after the rising edge of the GATE input. On terminal count, the OUT terminal goes low for one clock pulse then will go high again. The timing diagram for this mode of operation is shown in figure 9.22. As the low to high transition of the GATE terminal causes triggering hence this mode is referred to as hardware triggered strobe.

If the GATE input is made low to high again the counter is reloaded by the same count value. The down counting of the count value once again started and on the terminal count the OUT terminal goes low for one clock period.

Example 9.4. *An LED is connected to PA_0 of 8255 PPI. It should show ON and OFF regularly with a delay of one second. The delay should be introduced with 8253 used in mode 0 of counter 1. Assume the clock frequency applied to the counter of 8253 is 2 MHz.*

Solution. The control word to initialize 8253 is (Figure 9.23):

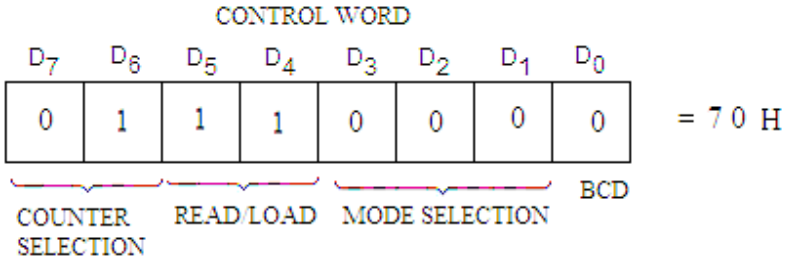


Fig. 9.23

The control word for latching operation for counter 2 is 80 H as shown in figure 9.24.

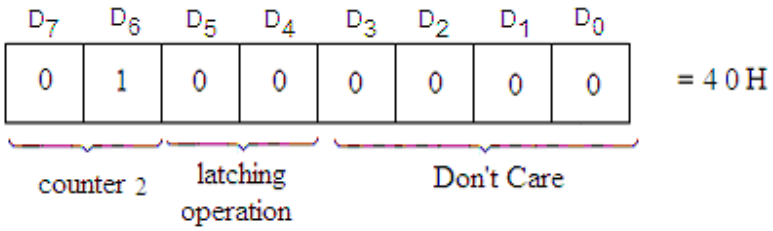

Fig. 9.24

Since the frequency of the clock signal connected to CLK terminal is 2 MHz, so the time of one clock pulse is 0.5 μ sec. If a count value of 50000_{10} (C350 H) is loaded to the counter, then a delay of 25 msec may be introduced when the counter is used in mode 0. Further to introduce a total time delay of 1 sec, then the subroutine program used for 25 msec may be executed 40 (28 H) times. Thus the program having the subroutine is given below:

Main Program:

Label	**Mnemonics**	**Operand**	**Comments**
	LXI SP,	XXXX H	; Initialize stack pointer.
	MVI A,	80 H	; Initialize 8255 PPI with all the ports as output ports.
	OUT	03 H	; The control word is loaded to the control word register of 8255.
	MVI B,	00 H	; Load the register B with 00 H.

```
        MOV  A,    B        ; 00 H is stored in accumulator.
LOOP1   OUT        00 H     ; 00 is send to port A of 8255 so that
                            LED is OFF.
        MVI  C,    28 H     ; C register is used as counter so that
                            the delay subroutine is executed 40
                            times.
LOOP    CALL       DELAY    ; Delay program for the delay of 25
                            msec is called.
        DCR C               ; Decrement C.
        JNZ        LOOP     ; If the content in C becomes zero,
                            jump to LOOP.
        MOV  A,    B        ; Move the content of B in
                            accumulator.
        CMA                 ; Complement the accumulator
                            contents.
        MOV  B,    A        ; Complemented content of
                            accumulator is stored in B register.
        JMP        LOOP1    ; Jump to LOOP1 to change the state
                            of LED.
```

Subroutine Program:

```
DELAY   MVI  A,    70 H     ; Accumulator is loaded with the
                            control word 70 H to Initialize
                            counter 1 of  8253.
        OUT        13 H     ; Write the control word in the
                            control word register of 8253.
        MVI  A,    50 H     ; Load accumulator first with LS
                            byte (50 H) of the count value
                            C350 H.
        OUT        11 H     ; 50 H of the count value is loaded
                            to the counter 1 of 8253.
        MVI  A,    C3 H     ; Load accumulator then with MS
                            byte (C3 H) of the count value.
        OUT        11 H     ; C3 H of the count value is loaded
                            to the counter 1 of 8253.
AGAIN   MVI  A,    40 H     ; Control word 40 H is loaded to
                            accumulator to read on fly the
                            count value of the counter 1.
        OUT        13 H     ; The control word is loaded in the
                            control word register of 8253.
        IN         11 H     ; First read the LS byte of the count
                            value.
        MOV  D,    A        ; Load this value to D-register.
        IN         11 H     ; Read the MS byte of the count
                            value.
        ORA  D              ; Logical OR the LS and MS byte to
                            set zero flag.
```

```
        JNZ     AGAIN       ; If not zero jump to AGAIN.
        RET                 ; Return to main program.
```

Example 9.5. *The OUT terminal of counter 0 of 8253 is connected to RST 7.5, which is used to interrupt the microprocessor to clear the memory locations 2100 H to 21FF H. Use counter 0 of 8253 in mode 0 to enable RST 7.5 after a delay of 32.5 msec. Assume the clock frequency applied to the counter 0 of 8253 is 2 MHz.*

Solution. The control word to initialize counter 0 of 8253 is:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	0	1	1	0	0	0	0	= 30 H

The accumulator contents for SIM to enable RST 7.5, RST 6.5 and RST 5.5 are given by:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
SOD	SOE	X	R7.5	MSE	M7.5	M6.5	M5.5	
0	0	0	0	1	0	0	0	= 08 H

The clock frequency used for counter 0 is 2 MHz, so time for one clock pulse is 0.5 μsec. To introduce a delay of 32.5 *msec*, count value of 65000 (65000 x 0.5 μsec = 32.5 *msec*) is to be loaded to the counter 0. The hexadecimal equivalent of 65000_{10} is FDE8 H.

Main Program:

```
Label   Mnemonics   Operand     Comments
        EI                      ; Enable interrupts.
        MVI  A,     08 H        ; Bit pattern is loaded to
                                  accumulator to enable interrupts.
        SIM                     ; Enable interrupts.
        MVI  A,     30 H        ; Accumulator is loaded with the
                                  control word 30 H to Initialize
                                  counter 0 of 8253 in mode 0.
        OUT         13 H        ; Write the control word in the
                                  control word register of 8253.
        MVI  A,     E8 H        ; Load accumulator first with LS
                                  byte (E8 H) of the count value
                                  FDE8 H.
        OUT         10 H        ; E8 H of the count value is loaded
                                  to the counter 0 of 8253.
        MVI  A,     FD H        ; Load accumulator then with MS
                                  byte (FD H) of the count value.
        OUT         10 H        ; FD H of the count value is loaded
                                  to the counter 0 of 8253.
HERE    JMP         HERE        ; Wait for interrupt.
```

As soon as the counting is over, the OUT terminal of counter 0 becomes high which enables RST 7.5. The RST 7.5 interrupts the microprocessor and the program jumps to its vector location 003C H. At this vector location say it is stored JMP FFBD H. So the monitor will transfer the program from FFBD H. Now the user transfers the program from FFBD H to a memory location where service subroutine program for RST 7.5 is

stored. The program in service subroutine will be stored to clear the memory location 2100 H to 21FF H.

Interrupt Service Subroutine:

Label	**Mnemonics**	**Operand**	**Comments**
	LXI H,	2100 H	; H-L pair is loaded with 2100 H, starting address of the memory location.
	MVI C,	FF H	; Load FF H to C-register which is used as counter.
	XRA A		; Clear the accumulator.
LOOP	MOV M,	A	; Clear the memory location.
	INX H		; Increment the H-L register pair.
	DCR C		; Decrement the content of C-register for next byte.
	JNZ	LOOP	; If the contents of C-register are not zero then jump to LOOP for next byte.
	EI		; Enable interrupts.
	RET		; Return.

Example 9.6. *A positive going pulse is applied (figure 9.25) to the GATE terminal of counter 1 of 8253 used in mode 0. The RST 7.5 is used to interrupt the microprocessor. Write a program to measure the width of this pulse which is of approximately 1 second. The clock signal applied to CLK terminal of counter 1 is 10 KHz. The width should be stored in terms of counts in memory locations 2100 H and 2101 H.*

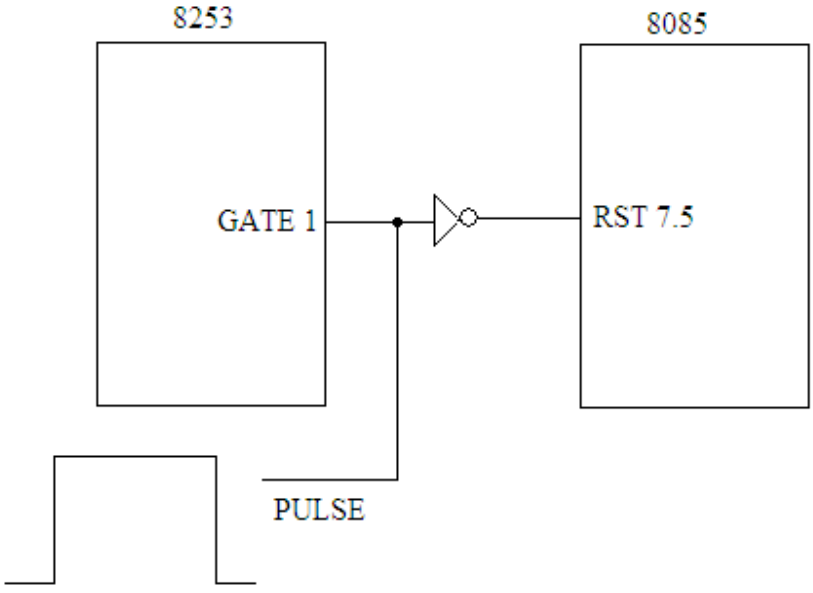

Fig. 9.25

Solution. The control word to initialize counter 1 of 8253 is:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	1	1	1	0	0	0	0	= 70 H

The accumulator contents for SIM to enable RST 7.5, RST 6.5 and RST 5.5 are given by:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
SOD	SOE	X	R 7.5	MSE	M 7.5	M 6.5	M 5.5	
0	0	0	0	1	0	0	0	= 08 H

The clock frequency used for counter 1 is 10 KMHz, so time for one clock pulse is 0.1 *msec*. This will also be measurement accuracy. Let us initialize the counter 1 with the count value corresponding to 2 second (1 sec for high and 1 sec for low). The count value will be 20000_{10}, (as 20000x0.1 msec = 2 sec). The hexadecimal equivalent of 20000_{10} is 4E20 H. So 4E20 H will be loaded as count value in counter 1.

To measure the pulse width the counter 1 is initialized in mode 0 in which signal (High pulse) on GATE terminal enables the counter; and RST 7. 5 is disabled. As soon as the pulse ends, the counting will be stopped and RST 7.5 will interrupt the microprocessor. The interrupt service subroutine will store the required number of counts in 2100 H and 2101 H memory locations. The required number of counts will be obtained by subtracting the remaining counts from the initial counts.

The program is therefore given by:

Main Program:

Label	**Mnemonics**	**Operand**	**Comments**
	EI		; Enable interrupts.
	MVI A,	08 H	; Bit pattern is loaded to accumulator to enable interrupts.
	SIM		; Enable interrupts.
	MVI A,	70 H	; Accumulator is loaded with the control word 70 H to Initialize counter 1 of 8253 in mode 0.
	OUT	13 H	; Write the control word in the control word register of 8253.
	MVI A,	20 H	; Load accumulator first with LS byte (20 H) of the count value 4E20 H.
	OUT	11 H	; 20 H of the count value is loaded to the counter 1 of 8253.
	MVI A,	4E H	; Load accumulator then with MS byte (4E H) of the count value.
	OUT	11 H	; 24E H of the count value is loaded to the counter 1 of 8253.
HERE	JMP	HERE	; Wait for interrupt.

Interrupt Service Subroutine:

Label	**Mnemonics**	**Operand**	**Comments**
	LXI H,	2100 H	; H-L pair is loaded with 2100 H, starting address of the memory location.
	IN	11 H	; Read the LS byte of the remaining counts.

```
MOV  D,     A        ; Store it to D-register.
IN          11 H     ; Read the MS byte of the remaining
                       counts.
MOV  E,     A        ; Store it to E-register. So the
                       remaining counts are stored in D-E
                       register pair.
MVI  A,     20 H     ; Initial maximum LS byte (20 H) is
                       stored in accumulator.
SUB  D               ; Subtract the remaining LS byte
                       from maximum LS byte.
MOV  M,     A        ; Store the counts in 2100 H.
INX  H               ; Increment the H-L register pair.
MVI A,      4E H     ; Initial maximum MS byte is stored
                       in accumulator.
SBB  E               ; Subtract with borrow the
                       remaining MS byte from the
                       maximum MS byte.
MOV  M,     A        ; Store the counts in 2101 H.

EI                   ; Enable interrupts.
RET                  ; Return.
```

Example 9.7. *The D_0 bit of 8255 A PPI is connected trigger input (GATE terminal) of counter 2 of 8253 as shown in figure 9.26. The counter 2 is used in mode 1. The count to be loaded to the counter 2 is 0A H. Write a program so that a wave, having low for 10 pulse duration and repeats, is generated. The CRO may be connected to the OUT terminal of counter 2 to see the wave shape.*

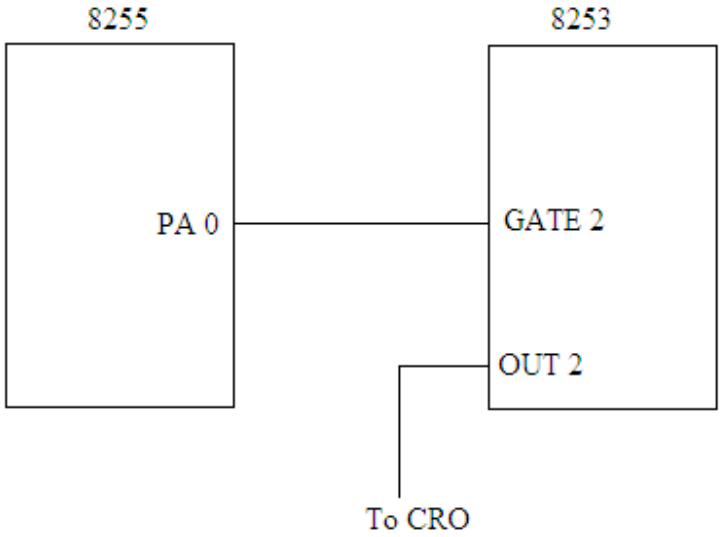

Fig. 9.26

Solution. The control word to initialize counter 0 of 8253 is:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
1	0	0	1	0	0	1	0	= A2 H

Main Program:

Label	Mnemonics	Operand	Comments
	MVI A,	30 H	; Accumulator is loaded with the control word 30 H to Initialize counter 2 of 8253 in mode 1.
	OUT	13 H	; Write the control word in the control word register of 8253.
	MVI A,	0A H	; Load accumulator 0A H as count value.
	OUT	12 H	; 0A H of the count value is loaded to the counter 2 of 8253.
	MVI A,	80 H	; Initialize 8255 A PPI with all the ports to use as output ports.
	OUT	03 H	; 80 H is loaded to control word register of 8255.
	MVI A,	00 H	; Store 00 H to accumulator.
	OUT	00 H	; PA0 is zero.
	MVI A,	01	; Store 01 H to accumulator to make PA0 as 1.
	OUT	00 H	; PA0 is 1.
	CALL	DELAY	; Call a delay program to introduce a small delay.
	JMP	LOOP	; Jump to LOOP for repetition.

DELAY SUBROUTINE:

Label	Mnemonics	Operand	Comments
DELAY	MVI C,	FF H	; Store FF H to C register to use it as counter.
LOOP	DCR C		; Decrement counter.
	JNZ	LOOP	; If count is not zero jump to LOOP.
	RET		; Return to main program.

Example 9.8. *Write a program that will count the approximate number of T-states in a program given below. The SOD line of 8085 is connected to the GATE terminal of counter 1 of 8253. The 8253 is used in mode 1. The crystal of 8085 is of 2 MHZ which is directly connected to CLK input of the counter. The number of T-states used is to be stored in memory locations 2200 H and 2201 H.*

Label	***Mnemonics***	***Operand***
	LHLD	*2101 H*
	XCHG	
	LHLD	*2103 H*
	MVI C,	*00 H*
	DAD D	
	JNC	*NXT*
	INR C	
NXT	*SHLD*	*2105 H*

```
MOV A,      C
STA         2107 H
HLT
```

Solution. The control word to initialize counter 1 of 8253 in mode 1 is:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	1	1	1	0	0	1	0	= 72 H

Let us load FFFF H as count value in counter 2.

Main Program:

Label	Mnemonics	Operand	Comments
	MVI A,	72 H	; Accumulator is loaded with the control word 72 H to Initialize counter 1 of 8253 in mode 1.
	OUT	13 H	; Write the control word in the control word register of 8253.
	MVI A,	FF H	; Load accumulator with low byte of count value.
	OUT	11 H	; Low byte FF H of the count value is loaded to the counter 1 of 8253.
	MVI A,	FF H	; Load accumulator with High byte of count value.
	OUT	11 H	; High byte FF H of the count value is loaded to the counter 1 of 8253.
	CALL	MODPRG	; Call the modified program.
	LXI H,	2200 H	; H-L pair is loaded with 2200 H, starting address of the memory location.
	IN	11 H	; Read the LS byte of the remaining counts.
	MOV D,	A	; Store it to D-register.
	IN	11 H	; Read the MS byte of the remaining counts.
	MOV E,	A	; Store it to E-register. So the remaining counts are stored in D-E register pair.
	MVI A,	FF H	; Initial maximum LS byte (FF H) is stored in accumulator.
	SUB D		; Subtract the remaining LS byte from maximum LS byte.
	MOV M,	A	; Store the counts in 2100 H.
	INX H		; Increment the H-L register pair.
	MVI A,	FF H	; Initial maximum MS byte is stored in accumulator.
	SBB E		; Subtract with borrow the remaining MS byte from the maximum MS byte.

```
        MOV  M,     A          ; Store the counts in 2101 H.
        EI                     ; Enable interrupts.
        HLT                    ; Stop processing.
```

Label	Mnemonics	Operand	Comments
MODPRG	MVI A,	C0 H	; Control word for enabling SOE and SOD.

Example 9.9. *Write a program to generate a negative pulse of approximately one T state after every 4 msec using 8253. Consider 1 MHz clock signal is applied to CLK terminal of the counter 1 of 8253.*

Solution. A negative pulse of approximately one T state is to be generated. This is the problem of rate generator, so 8253 may be used in mode 2. The counter 1 is to be initialized for this purpose. The GATE terminal is kept high. Further, clock frequency is 1 MHz so the time for one T state is 1 μsec.

The number of counts to be loaded for 2 msec delay is given by:

$$= \frac{4m\sec}{1\mu\sec} = 4000_{10}.$$

The number 4000 may be counted in BCD.

The control word to initialize counter 1 of 8253 in mode 2 is:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	1	1	1	0	1	0	1	= 7A H

The program is, therefore, written as:

Main Program:

Label	Mnemonics	Operand	Comments

	MVI A,	7A H	; Accumulator is loaded with the control word 7A H to Initialize counter 1 of 8253 in mode 2.
	OUT	13 H	; Write the control word in the control word register of 8253.
	MVI A,	00 H	; Load accumulator with low byte of count value.
	OUT	11 H	; Low byte 00 H of the count value is loaded to the counter 1 of 8253.
	MVI A,	40 H	; Load accumulator with High byte of count value.
	OUT	11 H	; High byte 40 H of the count value is loaded to the counter 1 of 8253.
	HLT		; Stop processing.

Example 9.10. *Use counter 1 of 8253 in mode 2 as divide-by-8 counter.*

Solution. The GATE terminal is kept high.

The control word to initialize counter 1 of 8253 in mode 2 is:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	1	0	1	0	1	0	0	= 54 H

The program is written as:

Main Program:

Label	Mnemonics	Operand	Comments
	MVI A,	54 H	; Accumulator is loaded with the control word 54 H to Initialize counter 1 of 8253 in mode 2.
	OUT	13 H	; Write the control word in the control word register of 8253.
	MVI A,	08 H	; Load accumulator with count value 08 H.
	OUT	11 H	; Count Value is loaded to the counter 1 of 8253.
	HLT		; Stop processing.

Example 9.11. *Write a program to generate a square wave of 3 KHz frequency using counter 1 of 8253. Consider 1.5 MHz clock signal is applied to CLK terminal of the counter.*

Solution. To generate square wave, we use the 8253 in mode 3. The count value to be loaded to the counter 1 is given by:

$$= \frac{1.5MHz}{3KHz} = 500_{10}.$$

So load 0500 H in BCD to counter 1. The GATE terminal of counter 1 kept high.

The control word to initialize counter 1 of 8253 in mode 2 is:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	1	1	1	0	1	1	1	= 77 H

The program is, therefore, written as:

Main Program:

Label	Mnemonics	Operand	Comments
	MVI A,	77 H	; Accumulator is loaded with the control word 77 H to Initialize counter 1 of 8253 in mode 3.
	OUT	13 H	; Write the control word in the control word register of 8253.
	MVI A,	00 H	; Load accumulator with low byte of count value.
	OUT	11 H	; Low byte 00 H of the count value is loaded to the counter 1 of 8253.
	MVI A,	50 H	; Load accumulator with High byte of count value.
	OUT	11 H	; High byte 50 H of the count value is loaded to the counter 1 of 8253.
	HLT		; Stop processing.

PROBLEMS

1. Draw the schematic block diagram of programmable interval timer (PIT) 8253 and explain its detail..
2. Discuss the control word format for 8253.
3. Describe Read/Write control logic for 8253.
4. Explain the different modes of 8253.
5. Discuss different applications of 8253.
6. Discuss how 8253 can be used as rate generator.
7. Discuss how 8253 can be used as programmable mono shot.
8. Discuss how 8253 can be used as square wave generator.
9. Discuss how 8253 can be used as software triggered strobe.
10. Discuss how 8253 can be used as hardware triggered strobe.
11. Explain how to generate a delay using 8253 in mode 0.
12. Explain how the count value loaded to a counter of 8253 is read while the counting is in progress.
13. Write a program to generate a square wave of 1 KHz using 8253 in mode 3. The CLK terminal of the counter used is connected to a clock frequency of 1 MHz.
14. Assume that CLK terminal of the counter 0 of 8253 is connected to clock frequency of 1 KHz. It is desired to generate square wave of 1 Hz frequency using this counter. Write a program to implement this.
15. Set up 8253 as a square wave generator of 1 msec time period, if the input frequency connected to CLK terminal of counter 0 is 1 MHz.
16. Write a program to generate a negative pulse of approximately one T-state after every 1 msec. Consider 2 MHz clock frequency is applied to the CLK terminal of the counter 1.
17. Connect PC_0 of 8255 A PPI to the trigger input (GATE 0) of counter 0 of 8253 used in mode 1. Load the count 0024 H (binary). Write a program to generate a wave having low for 36 pulses and repeat.

18. The OUT terminal of counter 0 of 8253 is connected to RST 7.5. It is used to interrupt the microprocessor to set SOD line of 8085 after a delay of 40 msec. Use counter 0 in mode 0 and clock frequency connected to the CLK terminal is 2 MHz.
19. An LED is connected to SOD line of 8085. The should glow ON/OFF regularly with an interval of 1 sec. The delay should be introduced by counter 2 of 8253 used in mode 0. Consider clock frequency connected to the CLK terminal is 10 KHz.
20 Use 8253 in mode 3 as a square wave generator. Use count value as 10 H (BCD). The counter 1 is to be used for this purpose.
21. Use counter 0 of 8253 to generate a square wave of 10 KHz and simultaneously counter 1 as divide by N counter. (N = 10 H BCD). The clock frequency connected to the CLK terminals is 1 MHz.
22. Use counter 0 of 8253 as a simple counter in mode 0. After certain delay, read the counts when the counting is in progress.
23. The 8253 is interfaced with 8085 microprocessor as shown in figure 9.27. Specify the port addresses of the three counters and control word register.

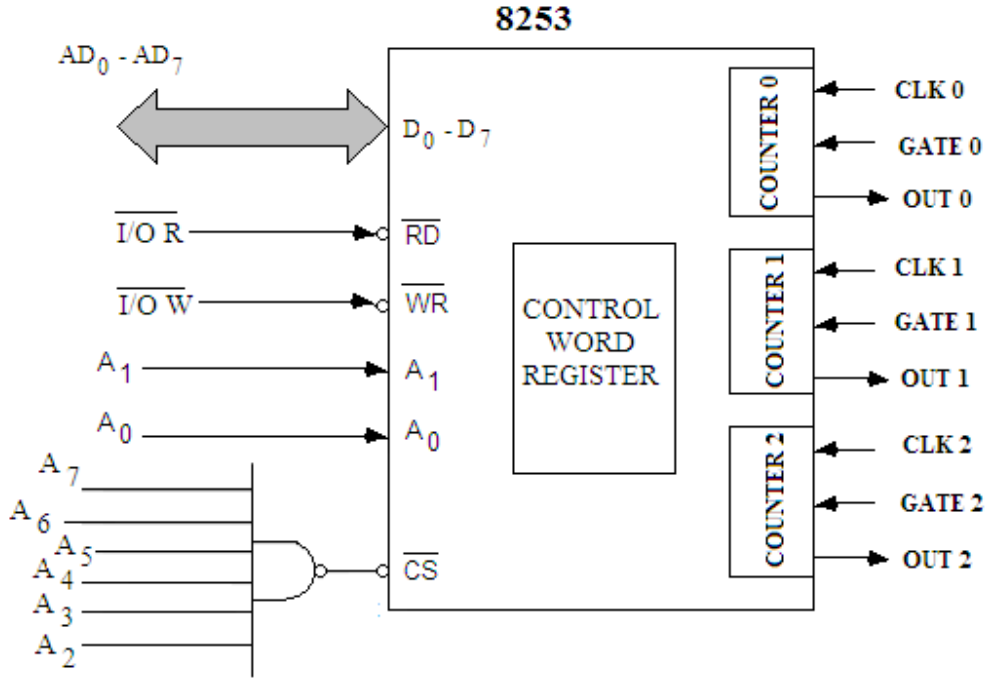

Fig. 9.27

(**Ans.: 00 H for counter 0**
01 H for counter 1
02 H for counter 2
03 H for CWR)

24. Specify the control words for 8253:
    (i) to program counter 1 in mode 5 having a 16-bit count value in BCD;
    (ii) to count the counts on fly for the counter 1.

(**Ans.: (i) 7B H, (ii) 40 H**)

25. Write a program to use counter 0 of 8253 in mode 0 for BCD operation with an initial count value 3648_{10}, and counter 2 in mode 3 for binary operation with an initial count value FF H.

(**Ans.: Program** **MVI A, 31 H**
OUT 13 H
MVI A, 96 H
OUT 13 H
MVI A, 48 H
OUT 10 H
MVI A, 36 H
OUT 10 H
MVI A, FF H
OUT 12 H
HLT)

26. Explain what will be the meaning of the following program for 8253;

(i)
```
MVI A, 94 H
OUT 13 H
MVI A, FF H
OUT 12 H
HLT
```

(ii)
```
MVI A, 38 H
OUT 13 H
MVI A, 04 H
OUT 10 H
MVI A, 02 H
OUT 10 H
HLT
```

(**Ans.: (i) Counter 1 in mode 2 with binary counting,**
(ii) Counter 0 in mode 4 with binary counting)

27. Write a program to use counter 0 of 8253 in mode 4 for BCD operation with an initial count value 0224_{10}.

28. Write a program to use counter 1 of 8253 in mode 5 for Binary operation with an initial count value $2AB6_{10.}$

Programmable Keyboard and Display Interface: 8279

The entering of program or data in the microprocessor base systems is most commonly done by a keyboard. Hence, keyboard is the most versatile input device. The keyboards with hexadecimal or ASCII characters are basically a combination of switches placed in a matrix with rows and columns. Similarly, display devices are to be connected to the system to output the data or the result, and the most common output device is seven segment display. The keyboard has to be constantly scanned to detect a key-press. The display, however, has to be supplied with the data to hold it ready. If the CPU is required to do all these operations itself, it will be heavily burdened and will have lesser time for other processes. These operations are, therefore, carried out by another device so that CPU is relieved from all these burdens. For this purpose, Intel 8279 keyboard/display interface is designed to directly connect to 8085 microprocessor. It performs both keyboard scan and output display operations repetitively and very short time of CPU is utilized for the data transfer between the device and CPU. This chapter will entirely deal with the details of this programmable keyboard and display device 8279.

10.1 INTEL PROGRAMMABLE KEYBOARD/DISPLAY INTERFACE 8279

Intel 8279 Programmable Key Board/Display Interface is available in the form of 40 pin IC in plastic dual in line package (DIP). It has been designed to interface the key board (an input device) and display device (an output device) with microprocessor. The 8279 constantly scans to detect a key press and transmit the information of characteristics of the key press to the CPU. It also displays or outputs the data received from CPU to the display devices. These two operations keyboard scan and display are performed repetitively and independently without utilizing the time of CPU except for relatively short time when the data is actually transferred to and from the burden of scanning the keyboard or refreshing the display repetitively.

There are three input modes:

Scanned keyboard mode
Scanned Sensor matrix mode
Strobed input mode.

The keyboard can provide a scanned interface to 64 contact key matrix or array of sensors or a srobed interface keyboard. Key depressions can be 2 key lock out or N-key rollover. Keyboard entries are debounced and strobed in an 8-character FIFO (First In First Out) and set the interrupt lines. If more than 8 characters are entered, overrun

interrupt status is set. The display provides a scanned display interface for LED, incandescent or other popular display technologies.

10.2 BLOCK DIAGRAM OF 8279

The pin diagram, logic diagram and functional block diagram of this 40 pin 8279 IC are depicted in figures 10.1, 10.2 and 10.3 respectively.

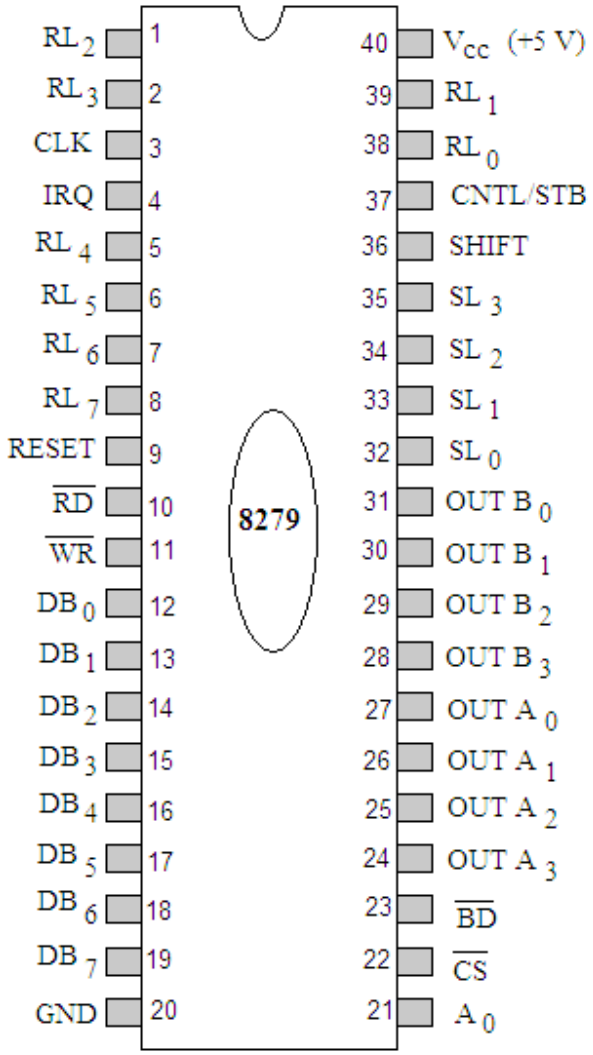

Fig. 10.1

The description of pins of 8279 Programmable keyboard/display interface is given as follows:

DB_0-DB_7: These pins form the bidirectional 8-bit data bus. The commands are also transmitted on this data bus.

CLK: It is a clock terminal to be connected to the external clock terminal of the system clock. It is used to generate internal timing. Maximum frequency to be used is 3 MHz.

$\overline{CS}$: This is a chip select terminal. A low signal to this terminal enables the chip for programming, reading the keyboard, etc.

A_0: It is buffer address pin. A low signal on this pin indicates data and a high on this pin indicates the command.

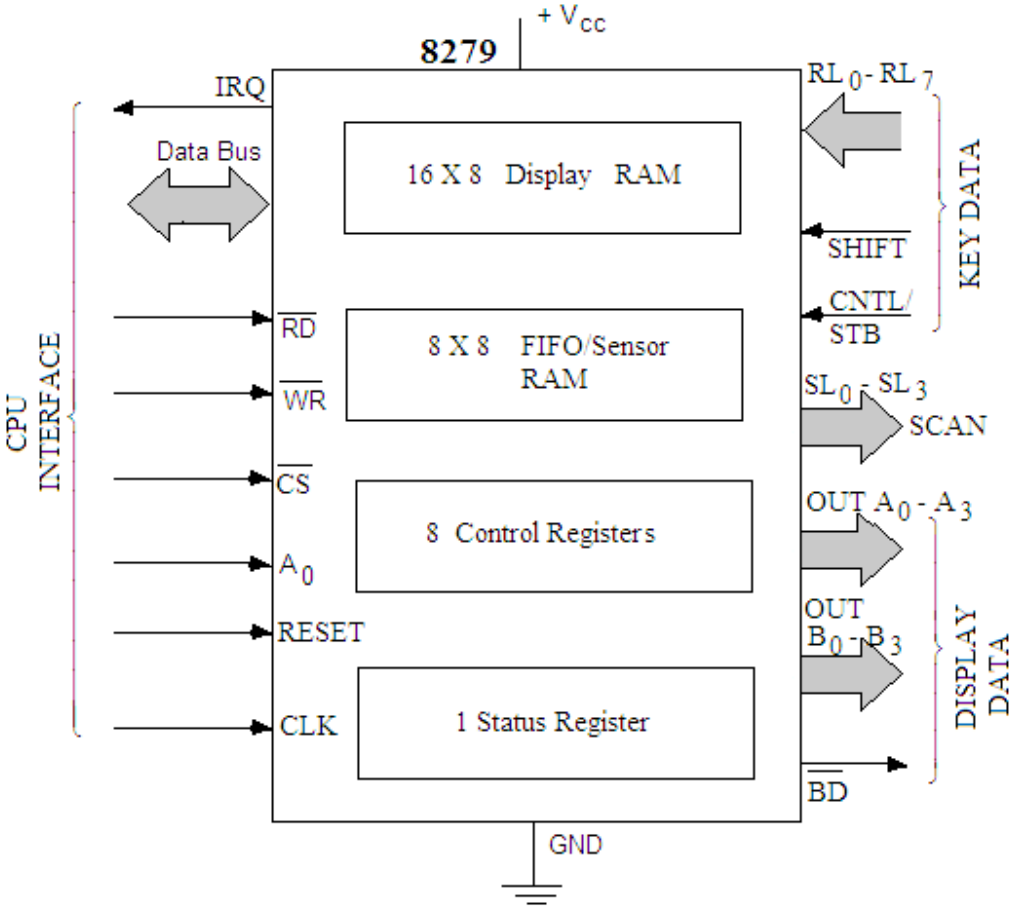

Fig. 10.2

IRQ: It is an interrupt request output terminal. Interrupt request, becomes 1 when a key is pressed, data is available.

SL_0-SL_3 : These four scan lines are used to scan the key switch or sensor matrix and the display digits. Scan line outputs scan both the keyboard and displays.

RL_0-RL_7: These are 8 Return line inputs which are connected to the scan lines through the key or sensor switches. These lines have internal pull-ups to keep high until a switch closure pulls one of the lines low.

SHIFT: This is an input terminal used in the scanned matrix keyboard modes. The SHIFT input status is stored along with the key position on key closure. SHIFT connects to shift key on keyboard.

CNTL/STB: This is control and strobe line, connected to the control key on the keyboard. It is high until a switch closure pulls it low.

SHIFT: This is an input terminal used in the scanned matrix keyboard modes. The SHIFT input status is stored along with the key position on key closure.

$\overline{RD}$: It is read input terminal and is connected to microprocessor's RD signal. It reads data/status registers.

$\overline{WR}$: It is write input terminal and is connected to microprocessor's write terminal.

OUT A_0 –OUT A_3 & OUT B_0-OUT B_3: These are two 4-bit ports. The display output is through two 4-bit ports (OUT A_0 –OUT A_3 and OUT B_0-OUT B_3). These two ports can be combined to form an 8 bit port.

$\overline{BD}$: This is a blanking display terminal, used to blank the display during the digit switching or by a display blanking command.

10.3 FUNCTIONAL DESCRIPTION OF 8279

The functional description of programmable keyboard and display interface 8279 will now be discussed with reference to figures 10.2 and 10.3. The 8279 has mainly been divided into four sections:

- Keyboard Section
- Scan Section
- Display Section
- Microprocessor Interface Section

Keyboard Section

The keyboard section includes Return buffer, keyboard debounce and control. Return buffers are to buffer the 8-input lines (RL_0-RL_7). In the keyboard mode, these lines are scanned, looking for the key closure in that row. If the debounce circuit detects a closed switch, it waits about 10 msec to check whether the switch remains closed. If it does, the address of the switch in the matrix in addition to other information is transferred to the FIFO.

The block FIFO/Sensor RAM and Status contains dual function 8 x 8 RAM. It will act as a FIFO in keyboard or strobed input modes. Each new entry is written into successive RAM positions and each is then read in the order of entry. FIFO status keeps track of the number of characters in the FIFO and whether it is full or empty. Too many reads or writes will be recognized as an error. The status can be read by $\overline{RD}$ and $\overline{CS}$ low and A_0 high. The status logic also provides an IRQ signal when the FIFO is not empty.

Scan Section

The scan section has a scan counter and four scan lines SL_0-SL_7 which are used o scan the key switch or sensor matrix and display digits. This counter can be operated in two ways: Encoded mode and Decoded mode. In the encoded mode, the counter provides a binary count which can be decoded to provide the scan lines for the keyboard or display. However, in case of decoded mode, the scan counter itself is a decoder providing 1 of 4 scan.

Display Section

This section contains the display address registers and display RAM. The display address registers hold the address of the word currently being written or read by the CPU and the two nibbles being displayed. The read/write addresses are programmed by CPU

command. They can also be set to auto increment after each read or write. The display RAM can be directly read by the CPU after the correct mode and address is set. These are two 4-bit ports. The display output is through two 4-bit ports (OUT A_0-OUT A_3 and OUT B_0-OUT B_3). These two ports can be combined to form an 8 bit port. The data from these lines are synchronized to the scan lines (SL_0-SL_3) for the multiplexed digit displays. The two ports may be blanked independently by the blanking display terminal $\overline{BD}$. This section also includes 16 x 8 display RAM and the processor can read from or write into any of these registers.

Microprocessor Interface Section

The microprocessor interface sections contains 8-bit bidirectional data lines (DB_0-DB_7), one interrupt request line (IRQ), one address buffer line A_0, and five lines ($\overline{RD}$, $\overline{WR}$, $\overline{CS}$, RESET, CLK) for interfacing. When a high signal appears on A_0 terminal, the command or status registers inside the 8279 can be accessed i.e. it works as command word or status. A low, however, on this line indicates that the data register, e.g. display RAM or the FIFO/Sensor RAM can be accessed. The interrupt request line IRQ becomes high whenever data entries are stored in the FIFO. This signal is used to interrupt the microprocessor to indicate the availability of the data. The data and commands are communicated between the microprocessor and the 8279 through the data bus (DB_0-DB_7). The RESET pin resets the 8279, when a high signal appears on this pin. The two signals $\overline{RD}$ and $\overline{WR}$ enable the data bus to either send data to external bus or receive it from the external bus.

10.4 KEYBOARD SCAN

As already discussed, the 8279 provides 4 scan lines (SL_0-SL_3) and 8 return lines (RL_0-RL_7). The scan lines can be operated either in encoded mode or in decoded mode.

Encoded Mode:

In this encoded mode, four scan lines (SL_0-SL_3) can be used to generate 16 lines with the help of external decoder. Usually 3 to 8 line decoder is used with the scan lines. The most significant scan line SL_3 is not recommended to use in keyboard decoder. So with three scan lines (SL_0-SL_2) and a 3 to 8 line decoder, 8 decoded scan lines are generated. These 8 decoded scan lines in conjunction with the 8 return lines can form an 8 x 8 keyboard matrix as shown in figure 10.4. Two more extra lines SHIFT and CNTL (control) can also provide four more different combinations as shown in table 10.1.

Table 10.1

SHIFT	CNTL
0	0
0	1
1	0
1	1

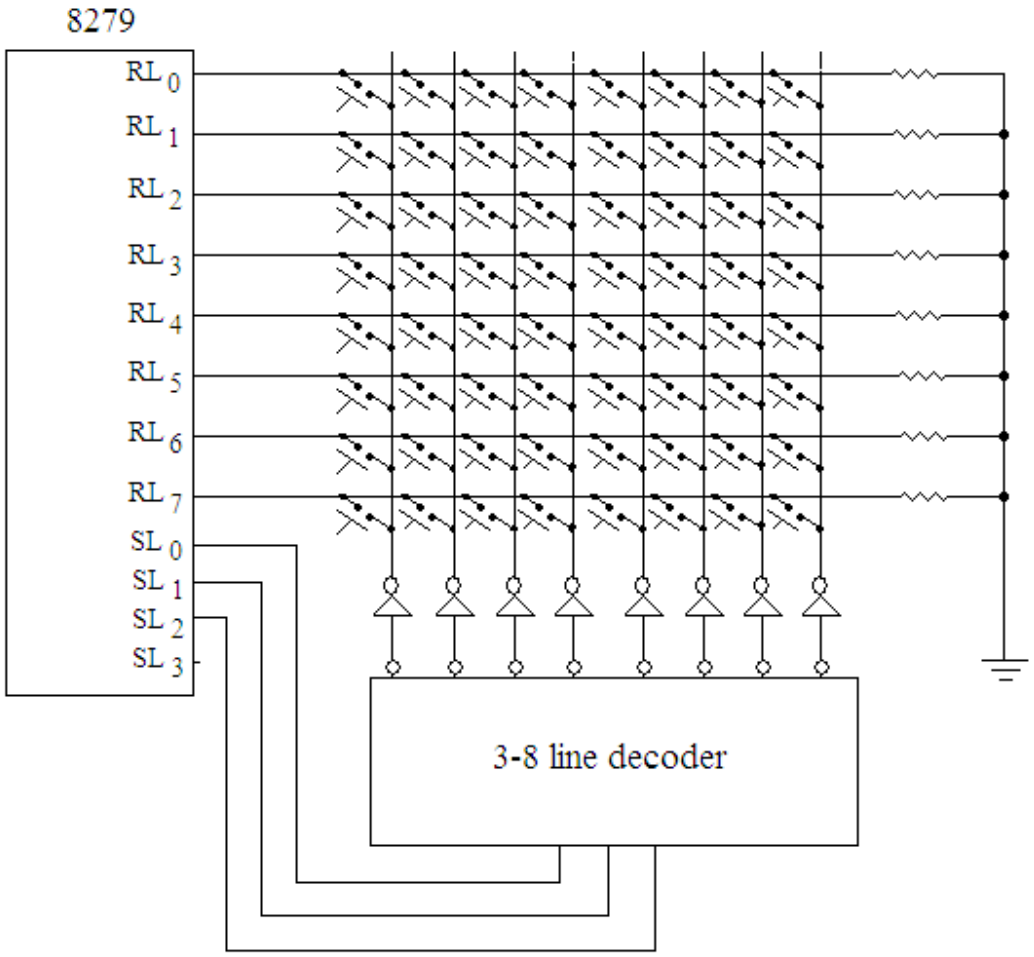

Fig. 10.4

With these four combinations and 8 x 8 matrix 4 x 8 x 8 = 256 character definitions are possible.

Decoded Mode:

In the decoded mode, an internal decoder is used to provide all the four scan lines (SL0-SL3) as the decoded lines as shown in table 10.2.

Table 10.2

SL_3	SL_2	SL_1	SL_0
0	0	0	1
0	0	1	0
0	1	0	0
1	0	0	0

These four decoded lines with 8 return lines form the keyboard matrix as shown in figure 10.5. The SHIFT and CNTL lines in combination with the keyboard matrix can provide 4 x 4 x 8 128 character definitions.

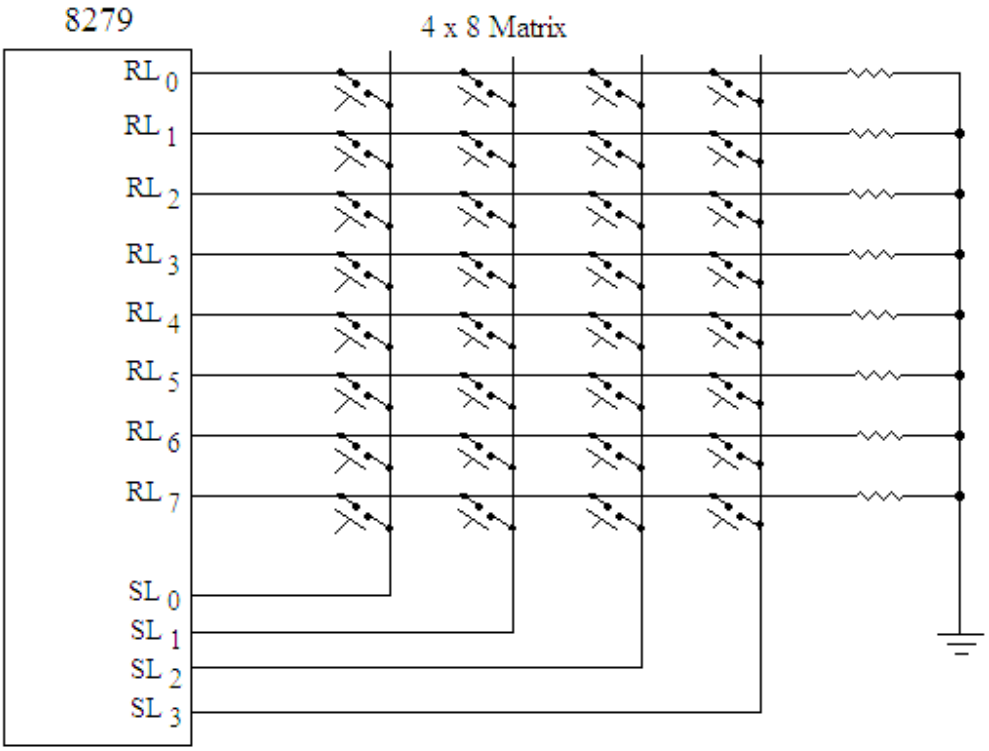

Fig. 10.5

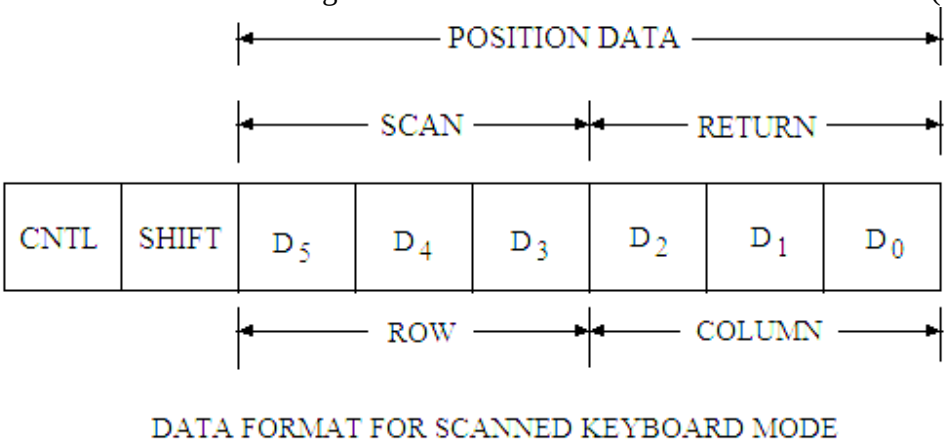
The disadvantage of the decoded scan is that the number of combinations of the scan lines as given in table is only four. Hence, only four rows can be used in case of keyboard and only four digits can be used for the display.

10.5 SCANNED KEYBOARD

In this mode, when a key is pressed, a unique 6 bit data is generated characteristic of the key position. An 8-bit word is formed, with the 6-bit position data for the key pressed and two bits for control (CNTL) and SHIFT lines. The format for the scanned keyboard mode is shown in figure 10.6. The scan counter has three scan bits (D_5-D_3) as



DATA FORMAT FOR SCANNED KEYBOARD MODE

Fig. 10.6

000 to 111 for the row on which the pressed key is located. The column counter also has three bits (D_2-D_0) as 000 to 111 for column on which the pressed key is located. Figure

10.7 shows the 8 x 8 keyboard matrix that has the 8 return lines and 8 scan lines. It has 64 key positions (0 to 63) which generate 8 bit data word for the key pressed. The 8 bit data word generated for a key pressed may be understood if we consider CNTL and SHIFT lines are 00. Suppose a key number 15 is pressed. The row line corresponding to the key number 15 is 1 (three bit binary is 001) and the column line for this pressed key is 7 (three bit binary is 111) so the 8 bit data formed for this pressed key becomes:

00 001 111

which is the binary equivalent of 15 (0F H). Similarly, the 8 bit data word for the key pressed 32 is 00 10 000 (20 H).

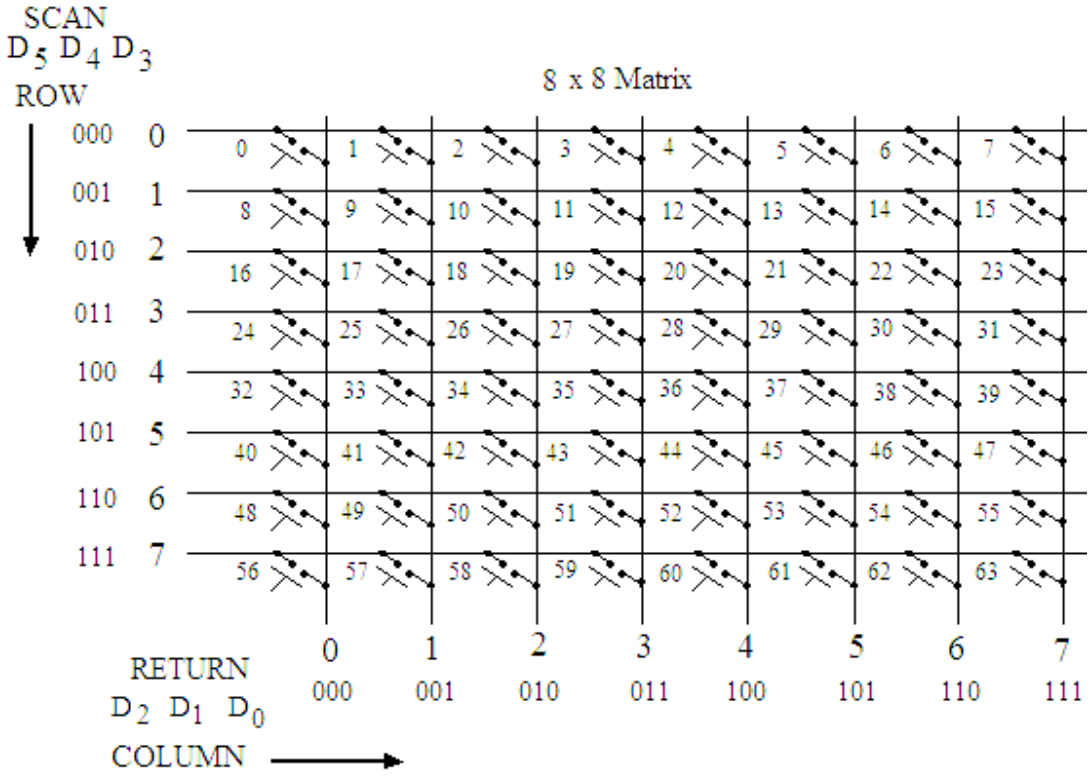


Fig. 10.7

The 8-bit data thus formed corresponding to the key pressed is stored in FIFO (first in first out) RAM inside the 8279. As soon as the 8-bit word is stored in FIFO RAM, IRQ terminal of 8279 goes high. This terminal is connected to one of the hardware interrupt line of CPU. With the high IRQ, the interrupt line of the CPU will be activated and the service subroutine program of the hardware interrupt will read the data from the FIFO RAM. As the data is read from the FIFO RAM, the IRQ terminal goes low; and it becomes high again if FIFO RAM contains further data.

The scanned keyboard mode has further two alternative ways of operation:

- Two-key lockout
- N-key rollover

10.5.1 Two-key Lockout

The mechanical keys used in the keyboard have a problem. When a key is pressed the contacts bounce back and forth and finally settle down after a small time. Due to this contact bounce problem multiple entries may be made for the same key. This can be avoided either by using the debouncing circuit using flip-flops etc. or by making the device to wait for few milliseconds after the key is pressed. In the 8279, second method is used for debouncing which is the built in feature of this IC.

In the two-key lockout operation, if two keys are depressed within the bounce cycle, it is called a simultaneous depression and neither key will be recognized until one of the keys is released. The last key released will be recognized and its corresponding 8-bit code will be entered in FIFO RAM.

If after the first key is depressed, and no other key is found to be depressed within next two scans, then it is taken as a single key depression and the code for the depressed key will be entered in FIFO RAM.

If after the first key depression, one or more additional key depression is detected within the next two scans, then there will be following two possibilities:

If all keys are released before the first pressed key, then the first key data will be entered in FIFO RAM.

If first key pressed is released before others, then the press key will be entirely ignored.

10.5.2 N-key Rollover

In this mode, each key depression is treated independent. If simultaneous key depression occurs then keys are recognized and entered in FIFO RAM according to the order of the key pressed. In fact when a key is pressed the debounce circuit inside the 8279 waits for two scans then checks if this key is still pressed. If this key is still pressed, the code for the key depressed is entered into FIFO RAM.

10.6 SCANNED SENSOR MATRIX

As discussed earlier, the keyboard matrix size is 8 x 8 in encoded scan lines and 4 x 8 in decoded scan lines. In this mode, the keys are placed in the form of matrix either in 8 x 8 encoded scan lines or 4 x 8 decoded scan lines, the scan lines form the columns and return lines form the rows of the keyboard matrix. The key status (open or closed) is stored in RAM which can be addressed by the CPU. The data on each of the eight lines enter directly in eight columns of sensor RAM; and each switch position maps to specific sensor RAM positions. The SHIFT and CNTL lines are not considered as inputs. The format for each row of the sensor RAM is shown in figure 10.8. The logic circuits can also be connected to the return lines which will be triggered by the scan lines. The debouncing circuit is not provided in this mode. It therefore has the advantage that the CPU knows how long the sensor was closed. The IRQ line goes high if a sensor value is found to have changed at the end of sensor matrix scan. The IRQ line is cleared by the first data read operation if the auto increment flag is set to zero or by the End Interrupt Command if the auto increment flag is set to one.

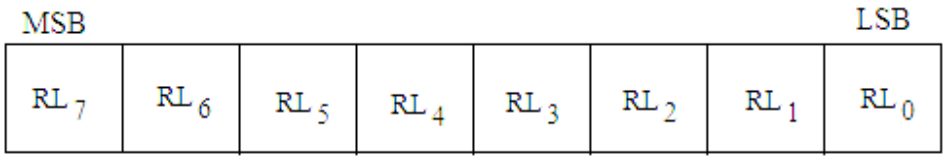

Fig. 10.8

10.7 STROBED INPUT

In this mode, the data is accepted from the return lines and go to FIFO RAM and entered at the rising edge of CNTL/STB line pulse. The data placed on the return lines can come from any source. The data is stored in the same format as shown in figure 10.8. Each scan line would lead to an 8-bit word.

10.8 DISPLAY INTERFACE

The interfacing of keyboard with the 8279 has been discussed in the preceding sections. The interfacing of display devices with the 8279 will now be discussed. Generally seven segment display devices are connected with 8279 using the multiplexing technique. In the multiplexing technique the seven segment code is sent to all the displays simultaneously, but the particular segment to be illuminated is only grounded (in case of common cathode displays).

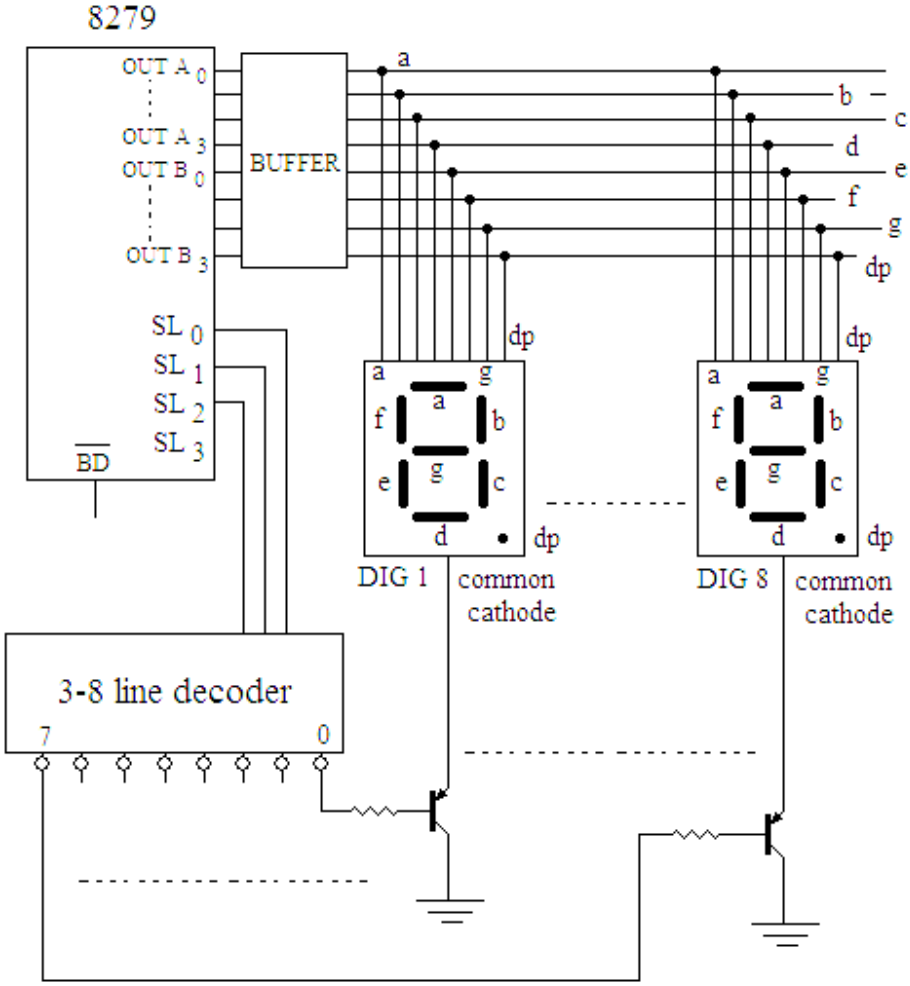

Fig. 10.9

In the 8279, eight output terminals, OUT A_0-A_3 and OUT B_0-B_3 are provided for the purpose of interfacing the seven segment displays. If a 4-to-16 line decoder is used with the scan lines (SL_0-SL_3), then a maximum of 16 display devices may be connected to the 8279. The internal FIFO RAM of 8279 can hold 8-bit data for 16 digits. If a 3-to-8

line decoder is used with three scan lines (SL_0-SL_2), then a maximum of 8 displays may be connected to this IC. All the segments of display devices are connected in parallel (i.e. a's segment of all the displays are tight together, similarly for b's to g's and dp's segments). These segments are then connected to the output terminals OUT A_0-A_3 and OUT B_0-B_3, as shown in figure 10.9. The OUT A_0, OUT A_1, OUT A_2 and OUT A_3 lines of the 8279 are connected to segments a, b, c and d respectively. The OUT B_0, OUT B_1, OUT B_2 and OUT B_3 lines of the 8279 are connected to segments e, f, g and dp respectively. The decoded outputs of scan lines provide 0 to 7 outputs in a periodic fashion, to select one digit of the display devices at a time. The $\overline{BD}$ line is used to blank all display digits.

When a given bit is 1, the corresponding segment is switched ON. For example the key code for the alphabet 'C' is obtained if the segments a, d, e and f are high. The data code for the alphabet 'C' is 93 as shown in figure 9.10.

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
A_3	A_2	A_1	A_0	B_3	B_2	B_1	B_0	Out terminals of 8279
d	c	b	a	dp	g	f	e	Segments of display
1	0	0	1	0	0	1	1	= 93 H

Fig. 10.10

10.9 DISPLAY MODES

The interfacing of display devices with 8279 has been discussed in the earlier section. Further there are following two options for the display formats in the display modes of 8279:

- Left Entry Mode (Type Writer Mode)
- Right Entry Mode (Calculator Mode)

10.9.1 Left Entry Mode (Type Writer Mode)

In the left entry mode, the first location of the display RAM data is treated as the segment for the left most digit and second location of the display is treated as the segment data for the second digit from the left and so on. This is similar to typing the paper with

the type writer. In this mode there is auto-increment facility as in the type writer; the

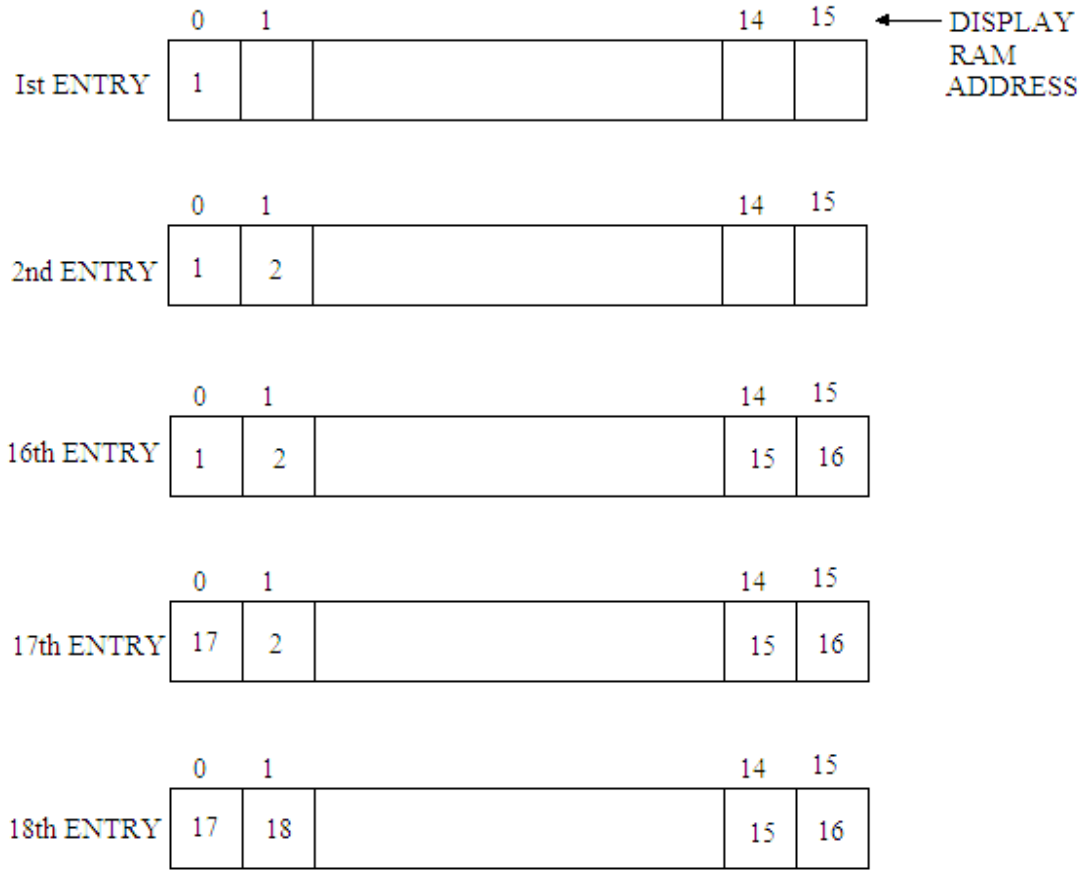

Fig. 10.11

carriage advances one step during typing. The left entry mode with auto increment facility is illustrated in figure 10.11 for 16 digits to be displayed on the display devices. From this figure it is clear that the first entry goes to the address 0 (first one of sixteen) for one word RAM and to the left most display position. The second entry goes to address 1 and the second display position and so on. The 16^{th} entry goes to the address 15 of the display RAM and position 16 of the display. The 17^{th} entry fill the left most position again.

There is a command (the details of which will be discussed in the next section) which allows entering data at an arbitrary address location of the display RAM. Figure 10.12 illustrates the result of a command that is used to display the next data to the 6^{th} position using 8-digit display. The command word given here is 10010110 which contains 8 bits, the three most significant bits 100 represents the "write display RAM": the next bit 1 is for auto increment and the next four bits 0110 (6^{th}) are for the position at which it should start filling. This command does not lead to any undesirable result.

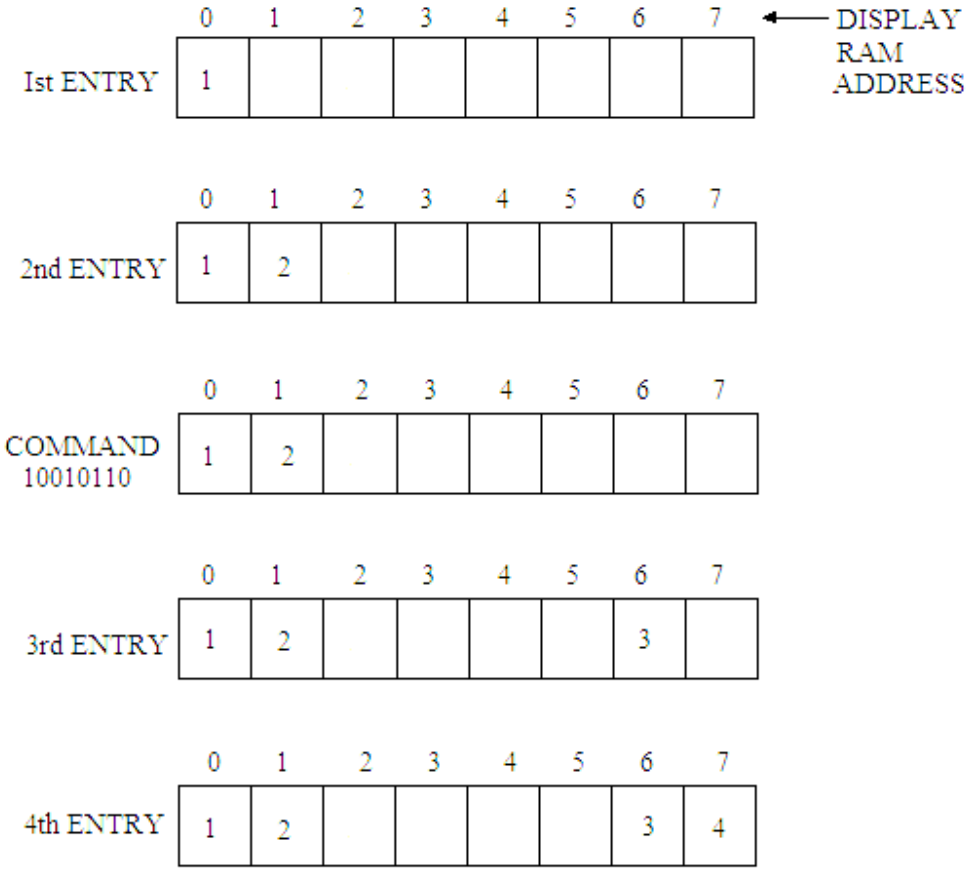

Fig. 10.12

10.9.2 Right Entry Mode (Calculator Mode)

The right entry mode is also known as calculator mode. In this mode the first location of the display RAM indicates the display data for the right most digit. Therefore, on the display, the data appears to start from the right and shift towards left as the digits move left in the calculator when the data is entered in to it. Figure 10.13 shows how the data are entered in this mode for 16 digits display with auto increment. The first character appears at the right display position. When a second character enters, the first character shifts towards the left by one place on the display. Similarly at the third entry, both the characters move by one place left each and the third character again takes the original right most position. It has been observed that a given character entered at a certain display position continues to remain there; but in case of right entry mode at every new entry each existing character moves one place to the left and finally the left most character shifts off the end, and is lost.

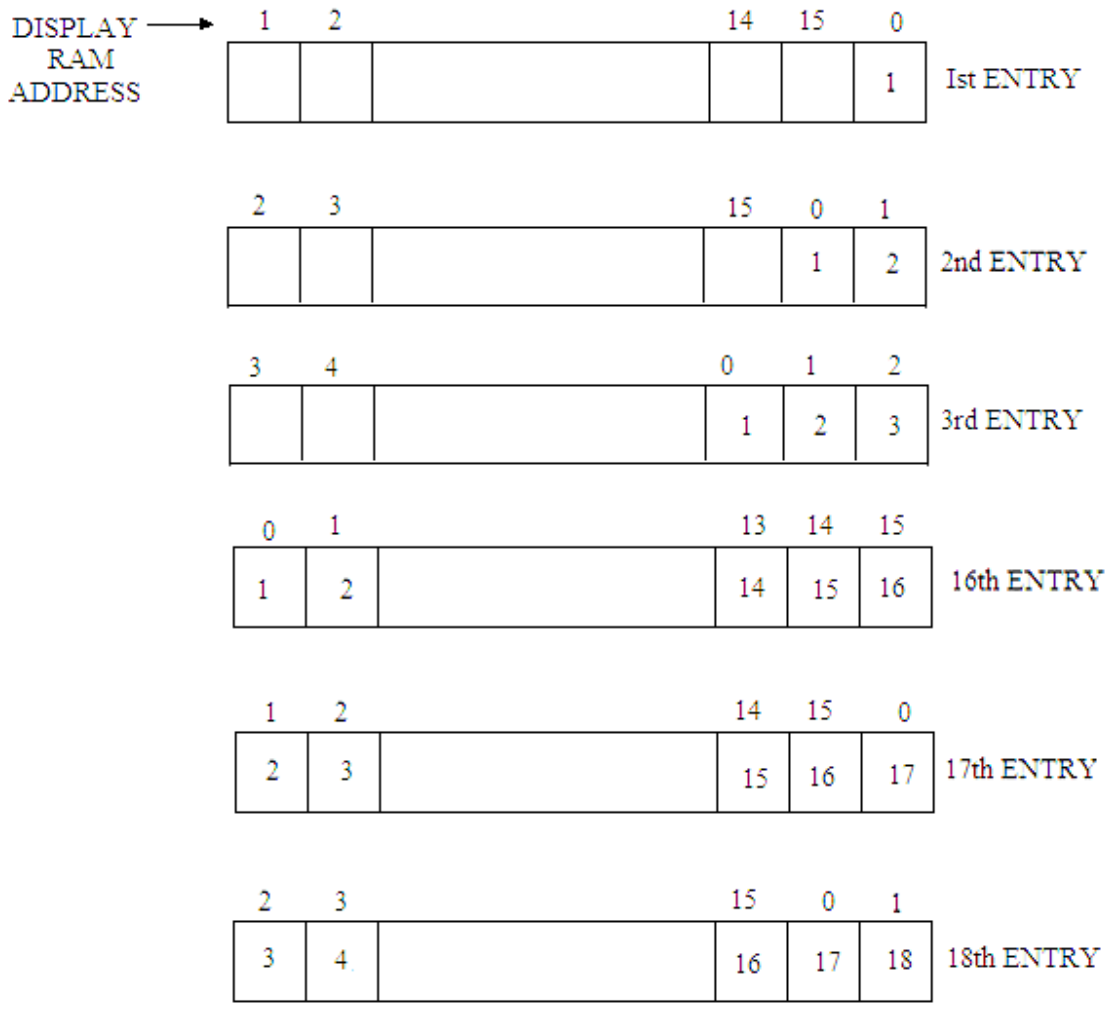

Fig. 10.13

Figure 10.14 shows the entering of the data in right entry mode with auto increment for 8 digit display using the command word for entering data at an arbitrary address location of the display RAM. The results obtained for entering data at an arbitrary address location in this mode are unexpected. Therefore, a starting display RAM address 0 and sequential entry are recommended in this right entry mode.

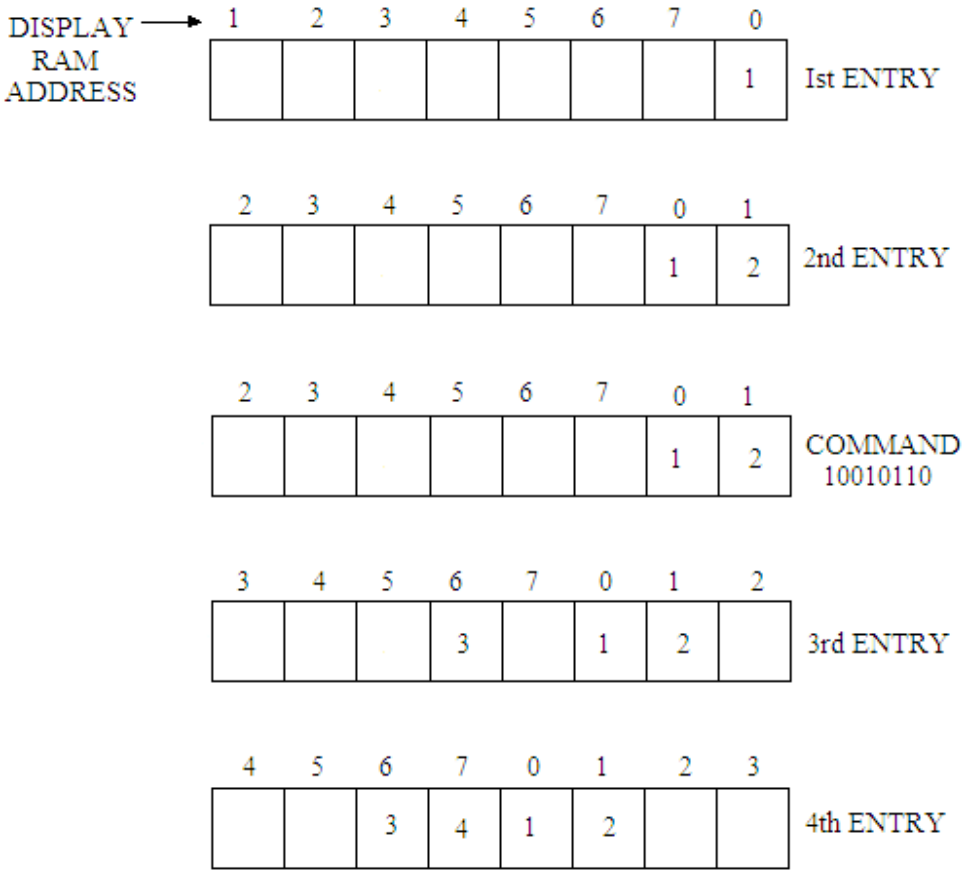

Fig. 10.14

10.10 PROGRAMMING OF 8279

The 8279 is a programmable keyboard and display interface device so it may be programmed for the desired operation. There are following 8 commands that can be used in the 8279:

- Keyboard/Display Mode Set
- Program Clock
- Read FIFO/Sensor RAM
- Read Display RAM
- Write Display RAM
- Display Write Inhibit/Blanking
- Clear
- End Interrupt/Error Mode Set

The command word, whose format is shown in figure 10.15, is sent on the data bus with $\overline{CS}$ low and A_0 high. The word is loaded to the 8279 using the write operation.

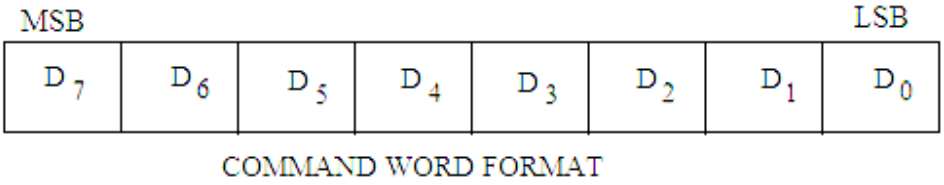

Fig.10.15

In this command word format, the three most significant bits selects the various operations which are given as:

D_7	D_6	D_5	**Function**
0	0	0	Keyboard/Display Mode Set
0	0	1	Program Clock
0	1	0	Read FIFO/Sensor RAM
0	1	1	Read Display RAM
1	0	0	Write Display RAM
1	0	1	Display Write Inhibit/Blanking
1	1	0	Clear
1	1	1	End Interrupt/Error Mode Set

10.10.1 Keybaord/Display Mode Set

This command sets up the operation of keyboard and display mode. The command bit pattern for the same is given as (figure 10.16):

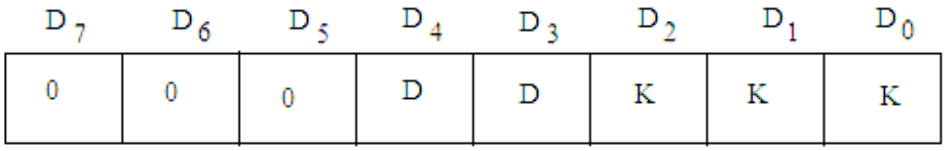

Fig. 10.16

D D represents the display mode and **K K K** represents the keyboard mode. **D D** in D_4 D_3 bit positions has the following four display mode options:

D_4	D_3	**Display Option**
0	0	Eight 8-bit character display with left entry
0	1	Sixteen 8-bit character display with left entry
1	0	Eight 8-bit character display with right entry
1	1	Sixteen 8-bit character display with right entry

K K K in D_2 D_1 D_0 bit positions has the following four display mode options:

D_2	D_1	D_0	Keyboard Option
0	0	0	Encoded Scan Keyboard with 2-key lockout
0	0	1	Decoded Scan Keyboard with 2-key lockout
0	1	0	Encoded Scan Keyboard with N-key roll over
0	1	1	Decoded Scan Keyboard with N-key roll over
1	0	0	Encoded Scan Sensor Matrix
1	0	1	Decoded Scan Sensor Matrix
1	1	0	Strobed Input Encoded Display Scan
1	1	1	Strobed Input Decoded Display Scan

The command word to set decoded scan keyboard with 2-key lockout and to have eight 8-bit characters with right entry in the display mode can be shown as:

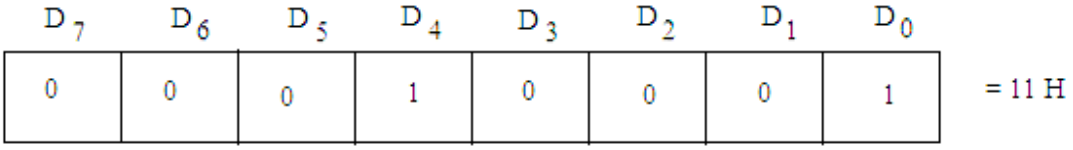

Fig. 10.17

If the address of the command port for 8279 is FF H, then by executing the following instructions, keyboard and display mode will be set as per the requirement discussed above:

```
MVI  A, 11 H
OUT  FF H
```

10.10.2 Program Clock

The different keys of the keyboard are scanned one by one in a sequence to detect a key press by the 8279; and also key debouncing is implemented by this device. All these functions require the timing signal. The 8279, therefore, needs an internal clock. The frequency of this clock should be around 100 KHz. But the clock of the system (i.e. the frequency of the external clock terminal of 8085) is 3 MHz. This system clock or any other external clock signal of known frequency may be applied to the CLK terminal (pin no. 3) of 8279. The 8279 internally provides an arrangement so that the clock applied at the pin no. 3 may be divided by a known factor to get the clock frequency of about 100 KHz. The frequency division is possible by the software.

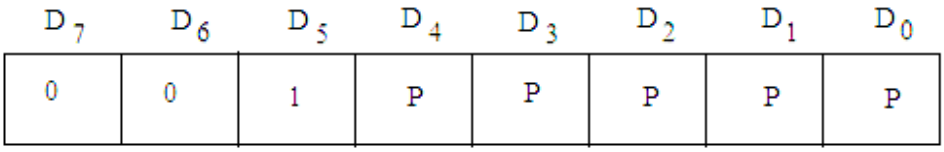

Fig. 10.18

A command word is generated to get the required clock frequency after division of the system clock or external clock connected to pin no. 3 of 8279. The command word format is given in figure 10.18.

The five bits (D_0 to D_4) of the command word define the scale factor. These five bits P P P P P may be set 0 0 0 0 0 to 1 1 1 1 1 whose decimal equivalents are 0 to 31. So the scale factor may be chosen up to 31.

The scale factor will be given by:

$$\text{Scale Factor} = \frac{\text{System} - \text{frequency}}{100\,\text{KHz}}$$

If the external clock frequency applied to pin 3 of 8279 is 2 MHz, then the scale factor will be:

$$\text{Scale Factor} = \frac{2\,\text{MHz}}{100\,\text{KHz}} = 20$$

The binary equivalent of 20 in five bits is 1 0 1 0 0 (represent P P P P P) and the command word will be given by (figure 10.19):

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	0	1	1	0	1	0	0	= 34 H

Fig. 10.19

Similarly, if the system clock frequency of 3 MHz is applied to 8279, then the scale factor is given by:

$$\text{Scale Factor} = \frac{3\,\text{MHz}}{100\,\text{KHz}} = 30$$

The binary equivalent of 30 is 1 1 1 1 0 and the command word will be given by (figure 10.20):

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	0	1	1	1	1	1	0	= 3E H

Fig. 10.20

The following instructions after execution will set the program clock to 100 KHz, if the system clock frequency of 3 MHz is applied to 8279. The command for this is 3E H as discussed above.

```
MVI  A, 3E H
OUT  FF H
```

The address of the command port for 8279 is assumed as FF H.

10.10.3 Read FIFO/Sensor RAM

The command word for setting up the 8279 to read FIFO/sensor RAM is shown in figure 10.21.

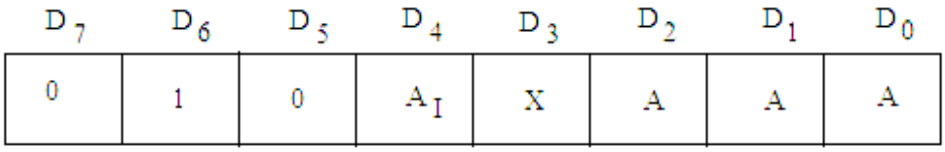

Fig. 10.21

The bits D_7 D_6 D_5 represent for command word 2 (0 1 0).

A_I represents Auto Increment.

X is don't care.

A A A (D_2 D_1 D_0) represent RAM address bits.

In the sensor matrix mode, the address bits A A A represent on the 8 rows of the sensor RAM. If A_I is set to 1, the successive Read operation is performed from the subsequent row of the sensor RAM. In the keyboard mode, auto increment bit AI and address bits A A A are irrelevant and the 8279 will automatically drive the data for each subsequent read (A_0 = 0) in the same sequence in which the data first entered in FIFO RAM.

If the data is to be read from the 3rd row of the sensor RAM, then the command word will be as:

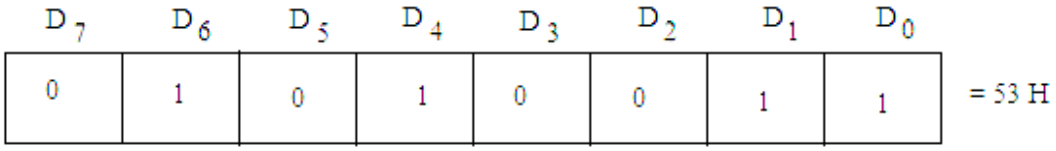

Fig. 10.22

10.10.4 Read Display RAM

The command word for setting up the 8279 to read display RAM is shown in figure 10.23.

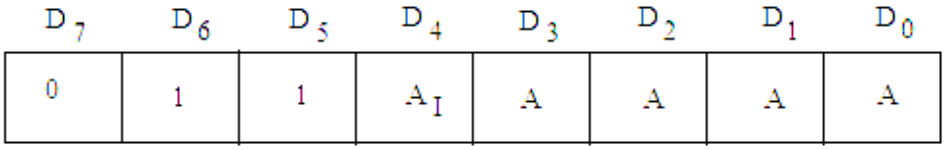

Fig. 10.23

The bits D_7 D_6 D_5 represent for command word 3 (0 1 1).

A_I represents Auto Increment.

A A A A (D_3 D_2 D_1 D_0) select one of the 16 rows of display RAM that is to be read.

If the auto increment bit A_I is set to 1, then the row address will automatically be incremented after each of the Read to display RAM. The command word 0 1 1 1 0 0 0 0 (= 70 H) represents a read from the display RAM.

10.10.5 Write Display RAM

To display information, the seven segment data is to be written in the internal display buffer. To enable writing seven segment data into display buffer, the write display RAM command has to be written into the command word register. The command word for the same is shown in figure 10.24.

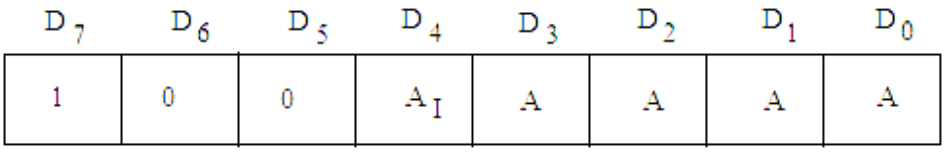

Fig. 10.24

The bits D_7 D_6 D_5	represent for command word 4 (1 0 0).
A_I	represents Auto Increment.
A A A A (D_3 D_2 D_1 D_0)	is the address of the digit that the CPU writes into the buffer. Four bit address is provided to select any one of the digits.

After the write command with A_0 = 1, all the subsequent writes with A_0 = 0 will be to the display RAM

For example, to write the segment codes 63 H and B5 H in the first and second locations of the display RAM, the command will be given as:

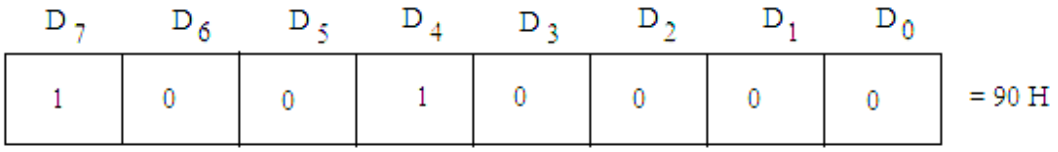

Fig. 10.25

The following instructions will write the segment codes 63 H and B5 H in the first and second locations of the display RAM:

```
MVI A, 90 H
OUT FF H
MVI A, 63 H
OUT FE H
MVI A, B5 H
OUT FE H
```

The first two instructions MVI A, 90 H and OUT FF H writes the command word in the command word register (FF H is the address of the command word register with A_0 is 1). The next two instructions MVI A, 63 H and OUT FE H writes the segment code 63 H in the first location of the display RAM (OUT FE H is the address for the same with A_0 = 0); and the last two instructions MVI A, B5 H and OUT FE H writes the segment data B5 H in the next location of display RAM as the in the command word auto increment A_I bit is set to 1.

10.10.6 Display Write Inhibit/Blanking

The control word for Display Write Inhibit/Blanking is shown in figure 10.26.

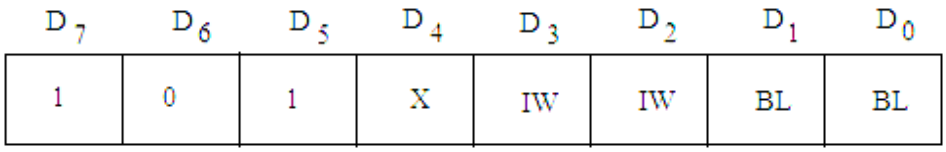

Fig. 10.26

The bits D_7 D_6 D_5 represent for command word 5 (1 0 1).

X represents don't care may be taken as 0.

IW Inhibit Write Flag.

BL Blank Display Flag.

The display write inhibit control word inhibits writing to either left most 4 bits of the display or right most 4 bits. By setting D_3 (IW) bit to 1, the left most significant 4 bits of the display will be masked or inhibited and similarly, by setting D_2 (IW) bit to 1, the right most significant 4 bits will be masked or inhibited.

Similarly, the blank flag (BL) blanks half of the output pins. By setting D1 (BL) bit to 1, the left most significant 4 bits will be blanked (or turned off); and by setting D0 (BL) bit to w, the right most significant 4 bits will be blanked.

10.10.7 Clear

The command word to clear the display, FIFO or both is shown in figure 10.27.

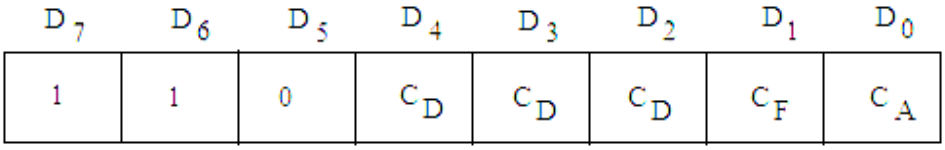

Fig. 10.27

The bits D_7 D_6 D_5 represent for command word 6 (1 1 0).

C_A Clears All (it clears both display RAM and FIFO).

C_F Clears FIFO Status and resets the IRQ line.

C_D C_D C_D Clears all rows of the display RAM to a selectable blanking code.

The selectable blanking code C_D C_D C_D is defined as follows:

C_D	C_D	C_D	
	0	X	All display RAM locations become 00000000 (all zeros).
	0	0	AB becomes 00100000 (20 H).
	1	1	All ones 11111111 (FF H).
			Enables clear display when 1.

If C_F bit is set to 1, it clears FIFO and the display RAM status, and sets address pointer to 000; it also resets the IRQ lne.

The bit C_A has the combined effect of CD and CF; if it is set to 1 it clears the display RAM and also clears FIFO status.

10.10.8 End Interrupt/Error Mode Set

The command word to end interrupt/error mode set is shown in figure 10.28.

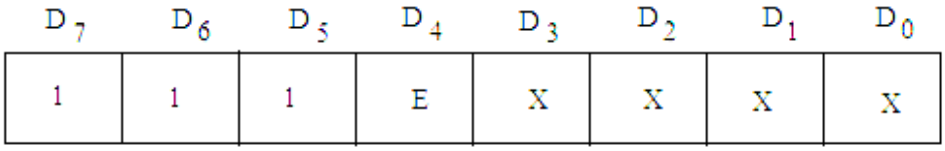

Fig. 10.28

The bits D_7 D_6 D_5 represent for command word 6 (1 1 0).

The bit D_4 represents Error (E) which may be programmed to set the error mode or clear the IRQ line.

The bits D_3 - D_0 are represented by X, means don't care and these may be considered as 0s.

For the sensor matrix mode this command lowers the IRQ line and enables writing into RAM.

For the N-key rollover if the bit E is programmed to 1 the chip will be operated in the special error mode.

10.11 STATUS REGISTER (IN OPERATION)

The status word gives the information about how many characters are in the FIFO RAM and whether an error has occurred. The status word can be read by the CPU when A_0 = 1 or in other words we can say that the status word can be read by the command register (IN FF H in the present case if FF H is the address of the command register).

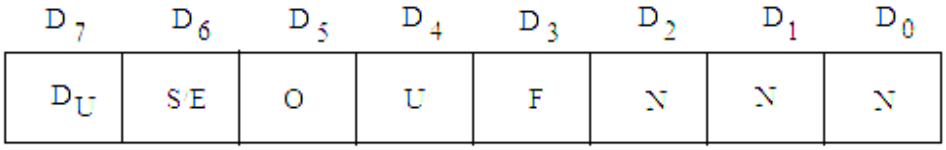

Fig. 10.29

The bit D_7 represents D_U - Display Unavailable.

The bit D_6 represents S/E - Sensor Closure/Error Flag for multiple closure.

The bit D_5 represents O- Over-run error.

The bit D_4 represents U- Under-run error.

The bit D_3 represents F- FIFO Full.

The bits D_2 to D_0 represent NNN as the number of key codes in FIFO RAM.

In this status word the first three bits D_2 to D_0 labeled as NNN identify the number of key codes or characters that are currently present in the FIFO.

The next bit F (D_3) indicates whether FIFO is Full or Empty. If F = 1, then it means FIFO is full. The FIFO is empty is F = 0.

The next two bits U and O (D_4 and D_5) are related to the under-run or over-run errors. Over-run error indicates that an attempt was made to enter the key code or character in FIFO RAM when it was already full. The other error under-run means the processor attempted to read the FIFO when it was empty.

In the special error mode, the bit S/E (D_6) is showing that an error flag gives an indication whether a simultaneous multiple closure error has occurred.

The most significant bit D_U (D_7) of the status word stands for display unavailable. When the clear display command is send, the 8279 clears the display and clearing requires some very small time. In this duration the display is unavailable and the data can not be read or written in display RAM. The bit D_U is 1 when clearing is going on and it is automatically reset when display RAM becomes available again for writing.

Read Operation

To read FIFO RAM for the keyboard data following steps are carried out:

Step I Send Keyboard/display command word to command register. Say:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	0	0	0	0	0	0	0	= 00 H

Eight 8-bit Character display - left entry.

Encoded scan keyboard - 2 Key lockout.

Step II A read FIFO RAM command is written into the command register as:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	1	0	A_I	X	A	A	A	
0	1	0	0	0	0	0	0	= 40 H

(A_I and A A A are irrelevant in sensor matrix mode).

Step III Read the status word by using IN instruction and port address is for A_0= 0. Further, status word is checked, if D_0 bit is 1. If it is 1, which indicates one character or key code is available in the first location of FIFO RAM.

Step IV Read FIFO RAM command word is entered into the command register.

Step V Now the key data can be read from the data register with A_0 = 0.

Using these steps program may be written as given below:

Program:

Label	**Mnemonics**	**Operand**	**Comments**
	MVI A,	00 H	; Encoded scan, 2 key lockout mode.
	OUT	FF H	; Keyboard display code is written in command register.
LOOP	IN	FF H	; Read the status word.
	ANI	01 H	; Check if D_0 is 1.

```
JZ      LOOP    ; If D0 = 0 then read the status word
                  again till D0 is 1.
MVI  A, 40 H    ; Load FIFO RAM command word
OUT     FF H    ; in command word register.
IN      FE H    ; Read the data register to take the
                  key code.
```

10.12 INTERFACING OF 8279 WITH 8085

Since the 8279 is an I/O device, so it can be used as memory mapped I/O device or I/O mapped I/O device. The interfacing of this IC with 8085 microprocessor is shown in figure 10.29.

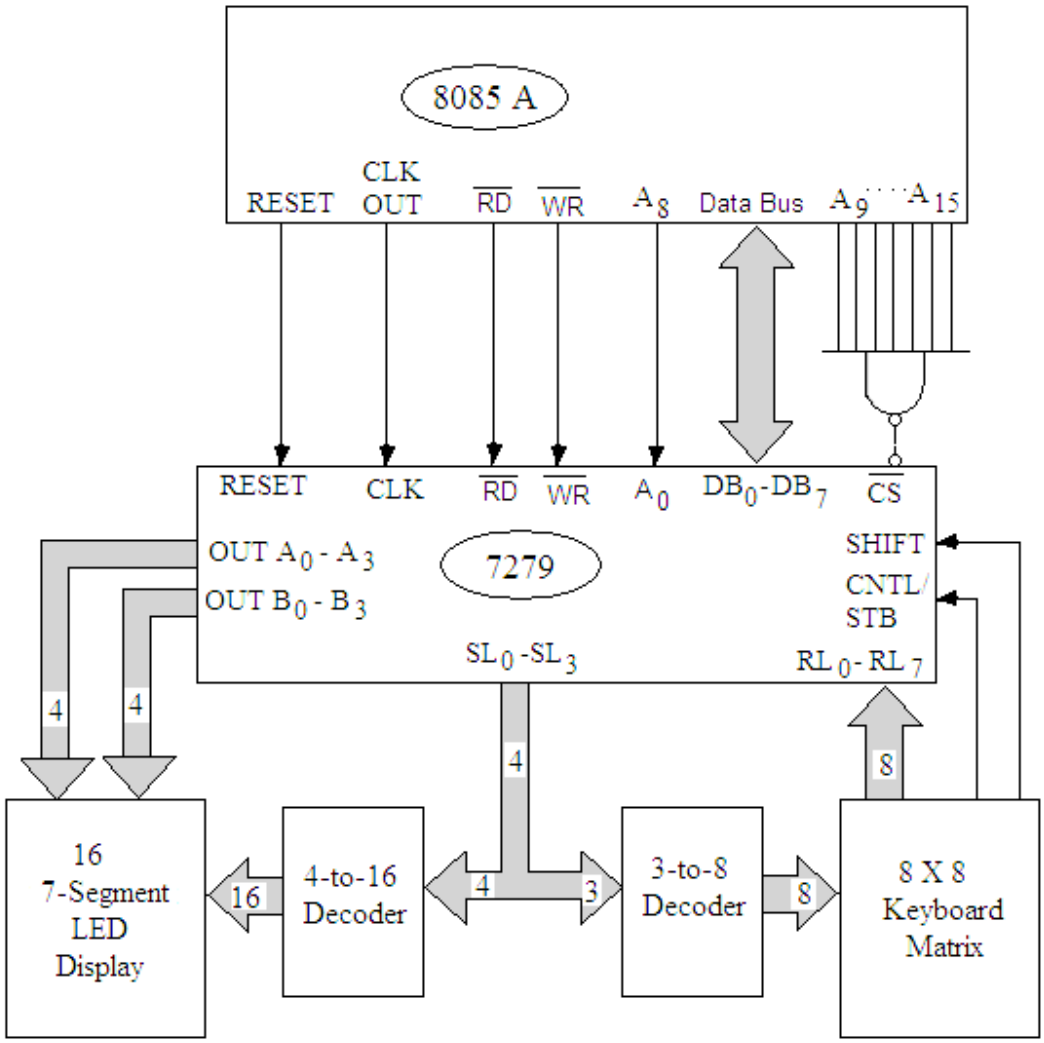

Fig. 10.29

The description of the connections of this IC with 8085 microprocessor is given below:

- The 8 data lines (DB_0-DB_7) are connected to the data bus of the microprocessor.

- The RESET signal of 8279 is connected to the RESET OUT terminal of the CPU.
- The active low terminals $\overline{RD}$ and $\overline{WR}$ of 8279 are connected to active low terminals $\overline{IOR}$ and $\overline{IOW}$ of the CPU.
- The CLK signal of this IC may be connected to either an external clock signal or the CLK OUT terminal of the processor.
- The buffer address terminal A_0 of 8279 is connected to the A_8 terminal of the address bus of the microprocessor. A low signal on this pin indicates data word and a high on this pin indicates the command word.
- The output of the address decoder circuit is connected to active low terminal $\overline{CS}$ of the IC 8279. The A_9-A_{15} terminals of the address bus of the microprocessor are connected to the inputs of the decoder circuit. These connections show that FF H is the address of the command register and FE H is the address of the data register.
- The Scan lines SL_0-SL_2 of the 8279 are connected to a 3 to 8 line decoder, the outputs of which are connected to the 8 x 8 keyboard matrix. The eight return lines RL_0-RL_7 along with the CNTL (control) and SHIFT terminals are also connected with the keyboard matrix.
- The sixteen 7-segment LED displays are also connected to this IC 8279 through the OUT A_0-A_3 and OUT B_0-B_3 terminals. The common terminals of the digit display are connected to the Scan lines SL0-SL3 through 4-to-16 line decoder.

Example 10.1. *A 4 x 4 keyboard matrix is to be interfaced with 8085 microprocessor using 8279. Give the necessary hardware for the same. Also give the software to enter the hex code of the key pressed and store this code to memory location 2500 H.*

Given frequency of the clock connected to the CLK terminal of 8279 is 2.5 MHz. Assume Decoded scan mode with N-key-roll over. Let control port address is 81 H and data port address is 80 H.

Solution. The hardware needed to interface 4 x 4 keyboard matrix with 8085 microprocessor is given in figure 10.30.

The initialization steps for providing the software are given below:

1. Send Keyboard/display command word to command register. Say:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	0	0	0	0	0	1	1	= 03 H

Eight 8-bit Character display - left entry.

decoded scan keyboard - N Key rollover.

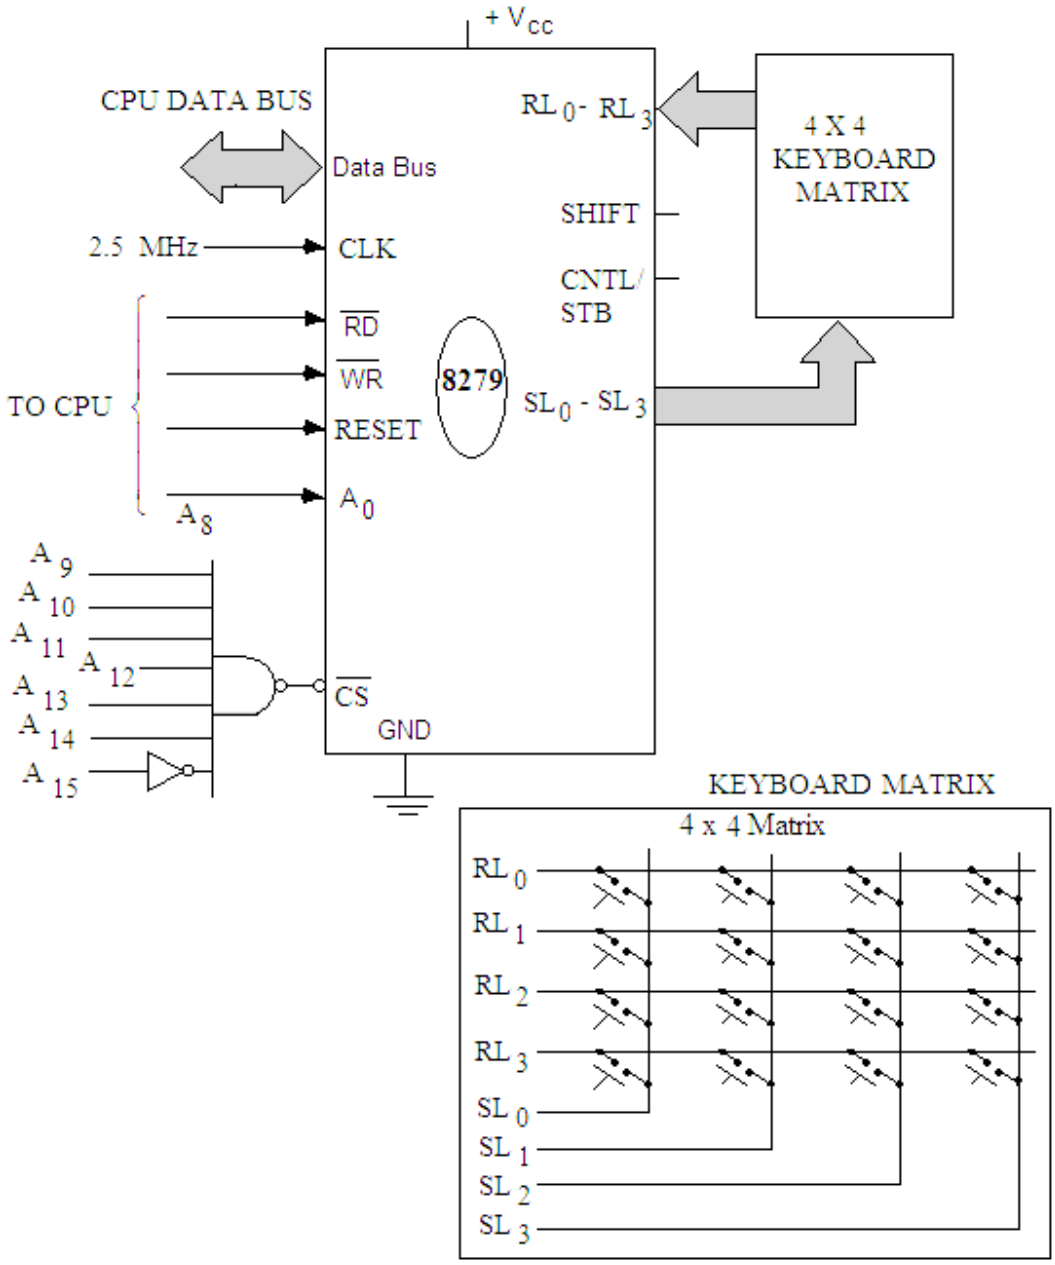

Fig. 10.30

2. The frequency of the clock is to be set around 100 KHz from 2.5 MHz. This frequency is to be divided by 25 generating the program clock word as:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	0	1	P	P	P	P	P	
0	0	1	1	1	0	0	1	= 39 H

11001 for PPPPP is 25.

3. Generate clear command word as:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
1	1	0	0	0	0	1	1	= C3 H

It will clear all.

4. A read FIFO RAM command is written into the command register as:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	1	0	A_I	X	A	A	A	
0	1	0	0	0	0	0	0	= 40 H

(A_I and A A A are irrelevant in sensor matrix mode).

5. Check the status word if the key is pressed.

The program for the same is written as:

Program:

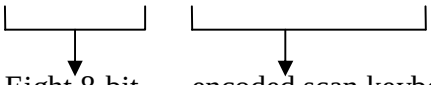
Label	**Mnemonics**	**0perand**	**Comments**
	MVI A,	03 H	; Decoded scan, N key roll-over mode.
	OUT	81 H	; Keyboard display code is written in command register.
	MVI A,	39 H	; Program clock
	OUT	81 H	; is set to 100 KHz.
	MVI A,	C3 H	; Clear FIFO.
	OUT	81 H	; Clear command word is loaded to command register.
LOOP	IN	81 H	; Read the status word.
	ANI	07 H	; Check if key pressed.
	JZ	LOOP	; If not then read the status word again till the key is pressed.
	MVI A,	40 H	; Load FIFO RAM command word
	OUT	81 H	; in command word register.
	IN	80 H	; Read the data register to take the key code.
	STA	2500 H	; Store the Hex code for the key pressed in memory location 2500 H.
	HLT		; Stop processing.

Example 10.2. *An 8279 is to be initialized with the following requirements:*
Keyboard encoded scan mode with N key rollover.
External clock frequency is 2 MHz.
Control port address is FF H and
Data port address is FE H.
The IRQ line of the 8279 is connected to the RST 7.5 interrupt of 8085A. Write an interrupt service routine to store the hex code of the key pressed in 2501 memory location.

Solution. The initialization steps for providing the software are given below:

1. Send Keyboard/display command word to command register. Say:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	0	0	0	0	0	1	0	= 02 H



Eight 8-bit Character display - left entry.

encoded scan keyboard - N Key rollover.

2. The frequency of the clock is to be set around 100 KHz from 2 MHz. This frequency is to be divided by 20 generating the program clock word as:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	0	1	P	P	P	P	P	
0	0	1	1	0	1	0	0	= 34 H

10100 for PPPPP is 20.

4. Generate clear command word as:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
1	1	0	0	0	0	1	1	= C3 H

It will clear all.

4. A read FIFO RAM command is written into the command register as:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	1	0	A_I	X	A	A	A	
0	1	0	0	0	0	0	0	= 40 H

(A_I and A A A are irrelevant in sensor matrix mode).

5. Check the status word if the key is pressed.

Program:

Label	**Mnemonics**	**Operand**	**Comments**
	MVI A,	02 H	; Encoded scan, N key roll-over mode.
	OUT	FF H	; Keyboard display code is written in command register.
	MVI A,	34 H	; Program clock
	OUT	FF H	; is set to 100 KHz.
	MVI A,	C3 H	; Clear FIFO.
	OUT	FF H	; Clear command word is loaded to command register.
	EI		; Enable interrupts.
	MVI A,	0B H	; Enable RST 7.5.
	SIM		; Set interrupt mask.

In this case when key code is available in FIFO RAM the IRQ line becomes high and enables RST 7.5 interrupt. The program will jump to the vector location 003C H of this interrupt, from where it jump to the service routine.

003C H	JMP	ISR	; Jump to service routine.

```
ISR     MVI  A,     40 H      ; Load FIFO RAM command word
        OUT         FF H      ; in command word register.
        IN          FE H      ; Read the data register to take the
                              key code.
        STA         2501 H    ; Store the Hex code for the key
                              pressed in memory location 2500
                              H.
        RET                   ; Return
```

Example 10.3. *An 8279 keyboard/display interface is used to drive eight 7-segmnet display in multiplexed mode. Write a program to initialize 8279 to display a message 'HELLO 07'.*

External clock frequency is 1.5 MHz.
Control port address is 19 H and
Data port address is 18 H.

Solution. The initialization steps for providing the software are given below:

1. Send Keyboard/display command word to command register. Say:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	0	0	0	0	0	0	0	= 00 H

Eight 8-bit Character display - left entry.

2. The frequency of the clock is to be set around 100 KHz from 1.5 MHz. This frequency is to be divided by 15 generating the program clock word as:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	0	1	P	P	P	P	P	
0	0	1	0	1	1	1	1	= 2F H

01111 for PPPPP is 15.

3. Generate clear command word as:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
1	1	0	1	0	0	1	1	= D3 H

It will clear all.

4. Display RAM command is written into the command register as:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
1	0	0	A_I	A	A	A	A	
1	0	0	1	0	0	0	0	= 90 H

(A_I =1 for auto increment and 0000 for A A A A as address bits).

Program:

```
Label   Mnemonics   Operand     Comments
        MVI  A,     00 H      ; 8 bit character display mode.
        OUT         19 H      ; Keyboard display code is written in
                              command register.
```

```
        MVI  A,     2F H    ; Program clock
        OUT         19 H    ; is set to 100 KHz.
        MVI  A,     D3 H    ; Clear FIFO.
        OUT         19 H    ; Clear command word is loaded to
                            command register.
UP      IN          19 H    ; Read the status word.
        ANI         80 H    ; Check if display available.
        JNZ         UP      ; If not available, read again.
        LXI  H,     2100 H  ; Point to the data in address
                            location.
        MVI  C,     08      ; C is used counter for eight
                            characters of 'HELLO 07'.
        MVI  A,     90 H    ; Write display command
        OUT         19 H    ; The command word is loaded in
                            command register.
REP     MOV  A,     M       ; Write the segment code in
        OUT         18 H    ; display RAM.
        INX  H              ; Increment H-L pair to point the
                            next code.
        DCR  C              ; Decrement C.
        JNZ         REP     ; If C is not zero jump to REP.
        HLT                 ; Stop processing.
```

Enter hex codes for HELLO 07 in the memory locations starting at 2100 H.

Location	**Hex code for**
2100 H	H
2101 H	E
2102 H	L
2103 H	L
2104 H	O
2105 H	- (Blank)
2106 H	0
2107 H	7

Example 10.4. *An 8 X 8 keyboard matrix (64 keys) and 8 common cathode seven segment displays are interfaced with 8085 through 8279. Write a program to initialize 8279 to display a message 'DISPLAY' on pressing key "0".*

External clock frequency is 2.0 MHz.
Control port address is 05 H and
Data port address is 04 H.

Solution. The initialization steps for providing the software are given below:

1. Send Keyboard/display command word to command register. Say:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	0	0	0	0	0	0	0	= 00 H

Eight 8-bit Character display - left entry.

2. The frequency of the clock is to be set around 100 KHz from 2.0 MHz. This frequency is to be divided by 20 generating the program clock word as:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	0	1	P	P	P	P	P	
0	0	1	1	0	1	0	0	= 34 H

10100 for PPPPP is 20.

3. Generate clear command word as:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
1	1	0	1	0	0	1	1	= D3 H

It will clear all.

4. Display RAM command is written into the command register as:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
1	0	0	A_I	A	A	A	A	
1	0	0	1	0	0	0	0	= 90 H

(A_I =1 for auto increment and 0000 for A A A A as address bits).

Program:

Label	**Mnemonics**	**Operand**	**Comments**
	MVI A,	00 H	; 8 bit character display mode.
	OUT	05 H	; Keyboard display code is written in command register.
	MVI A,	34 H	; Program clock
	OUT	05 H	; is set to 100 KHz.
	MVI A,	D3 H	; Clear FIFO.
	OUT	05 H	; Clear command word is loaded to command register.
UP	IN	05 H	; Read the status word.
	ANI	80 H	; Check if display available.
	JNZ	UP	; If not available, read again.
UP1	IN	05	; Read the status word again if the "0" is pressed.
	ANI	07 H	; Check for 0.
	JZ	UP1	; If zero, key "0" is not pressed repeat.
	MVI A,	40 H	; Load FIFO command word
	OUT	05 H	; in command word register.
REP	IN	04 H	; Read the data register to take the key code.

```
        CPI     00 H    ; Key "0" is pressed or not.
        JNZ     REP     ; If not repeat.
        LXI H,  2100 H  ; Point to the data in address location.
        MVI C,  07      ; C is used counter for eight characters of 'DISPLAY'.
        MVI A,  90 H    ; Write display command
        OUT     05 H    ; The command word is loaded in command register.
LOOP    MOV A,  M       ; Write the segment code in
        OUT     04 H    ; display RAM.
        INX H           ; Increment H-L pair to point the next code.
        DCR C           ; Decrement C.
        JNZ     LOOP    ; If C is not zero jump to REP.
        HLT             ; Stop processing.
```

Enter hex codes for DISPLAY in the memory locations starting at 2100 H.

Location	**Hex code for**
2100 H	D
2101 H	I
2102 H	S
2103 H	P
2104 H	L
2105 H	A
2106 H	Y

Example 10.5. *An 8279 keyboard/display interface is used to drive sixteen 7-segmnet display in multiplexed mode. Write a program to initialize 8279 to display a blinking message "CONGRATULATIONS".*

External clock frequency is 1.5 MHz.
Control port address is 19 H and
Data port address is 18 H.

Solution. The initialization steps for providing the software are given below:

1. Send Keyboard/display command word to command register. Say:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	0	0	0	1	0	0	0	= 08 H

Sixteen 8-bit Character display - left entry.

2. The frequency of the clock is to be set around 100 KHz from 1.5 MHz. This frequency is to be divided by 15 generating the program clock word as:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	0	1	P	P	P	P	P	
0	0	1	0	1	1	1	1	= 2F H

01111 for PPPPP is 15.

3. Generate clear command word as:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
1	1	0	1	0	0	1	1	= D3 H

It will clear all.

4. Display RAM command is written into the command register as:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
1	0	0	A_I	A	A	A	A	
1	0	0	1	0	0	0	0	= 90 H

(A_I =1 for auto increment and 0000 for A A A A as address bits).

Program:

Label	**Mnemonics**	**Operand**	**Comments**
	MVI A,	08 H	; 8 bit character display mode.
	OUT	19 H	; Keyboard display code is written in command register.
	MVI A,	2F H	; Program clock
	OUT	19 H	; is set to 100 KHz.
	MVI A,	D3 H	; Clear FIFO.
	OUT	19 H	; Clear command word is loaded to command register.
UP	IN	19 H	; Read the status word.
	ANI	80 H	; Check if display available.
	JNZ	UP	; If not available, read again.
LOOP	LXI H,	2100 H	; Point to the data in address location.
	MVI C,	0F	; C is used counter for 15 characters of 'CONGRATULATIONS'.
	MVI A,	90 H	; Write display command
	OUT	19 H	; The command word is loaded in command register.
REP	MOV A,	M	; Write the segment code in
	OUT	18 H	; display RAM.
	INX H		; Increment H-L pair to point the next code.
	DCR C		; Decrement C.
	JNZ	REP	; If C is not zero jump to REP.
	CALL	DELAY	; Introduce some delay using a Delay subroutine.
	CALL	CLEAR	; A subroutine to clear the display is used.
	CALL	DELAY	; Delay is introduce so that display is clear for some time.
	JUMP	LOOP	; Jump to repeat the display.

HLT ; Stop processing.

Enter hex codes for “CONGRATULATIONS” in the memory locations starting at 2100 H.

Location	**Hex code for**
2100 H	C
2101 H	O
2102 H	N
2103 H	G
2104 H	R
2105 H	A
2106 H	T
2107 H	U
2108 H	L
2109 H	A
210A H	T
210B H	I
210C H	O
210D H	N
210E H	S

PROBLEMS

1. Draw the function block diagram of Programmable Keyboard/Display interface 8279 and also discuss the function of each block.
2. Discuss three input modes of Keyboard scan of 8279.
3. Describe Scanned keyboard mode of 8279 with 2-key lockout and N-key rollover.
4. Discuss Scanned sensor matrix mode for 8279.
5. Discuss encoded mode of Keyboard scan of 8279.
6. Discuss decoded mode of Keyboard scan of 8279.
7. Describe left entry mode for display of 8279.
8. Name 8 command words of 8279 and discuss the command word format for the program clock.
9. Discuss the command word format for Read display RAM.
10. Discuss the command word format for keyboard/display mode set.
11. Discuss the command word format for Read FIFO/Sensor RAM.
12. Discuss the command word format for Display write Inhibit/blanking.
13. Discuss the command word format for End Interrupt/Error mode set.
14. Explain status register of 8279. How the status word can be read.
15. Discuss how 8279 can be interfaced with 8085A.
16. Mention various steps to be carried out for the initialization of 8279 with following specifications:
    Keyboard encoded scan mode with N key rollover.
    External clock frequency is 2 MHz.
    Control port address is 11 H and
    Data port address is 10 H.

17. An 8279 keyboard/display interface is used to drive sixteen 7-segmnet display in multiplexed mode. Write a program to initialize 8279 to display a blinking message "HAPPY BIRTH DAY".
    External clock frequency is 2.0 MHz.
    Control port address is 05 H and
    Data port address is 04 H.

18. An 8 x 8 keyboard matrix (64 keys) and 8 common cathode seven segment displays are interfaced with 8085 through 8279. Write a program to initialize 8279 to display a message 'PLEASE" on pressing key "0".
    External clock frequency is 2.5 MHz.
    Control port address is FF H and
    Data port address is FE H.

19. An 8279 keyboard/display interface is used to drive sixteen 7-segmnet display in multiplexed mode. Write a program to initialize 8279 to display a message 'BEST WISHES'.
    External clock frequency is 2.5 MHz.
    Control port address is 01 H and
    Data port address is 00 H.

20. An 8 x 8 keyboard matrix is to be interfaced with 8085 microprocessor using 8279. Give the necessary hardware for the same. Also give the software to enter the hex code of the key pressed and store this code to memory location 2500 H.
    Given frequency of the clock connected to the CLK terminal of 8279 is 2.5 MHz. Assume Decoded scan mode with N-key-roll over. Let control port address is 19 H and data port address is 18 H.

11

Programmable Interrupt Controller: 8259

This chapter will confine to the detailed discussion on Programmable Interrupt Controller (PIC) – 8259. This device is also called priority interrupt controller. It is designed to work with Intel 8080A, 8085A, 8086 and 8088 microprocessors. It works as an overall manager in an interrupt driven system environment. This device can handle 8 external interrupts and the starting address of the interrupts service routine can be vectored to any location in the memory map unlike the software and hardware interrupts which point to the predetermined starting address. The 8259 can be set to accept level triggered or edge triggered interrupts. The interrupt can be expanded to 64 interrupt inputs by cascading many 8259 device.

11.1 PROGRAMMABLE INTERRUPT CONTROLLER 8259

It n an earlier chapter it has been discussed that the 8085A has four hardware interrupt terminals namely TRAP, RST 5.5, RST 6.5 and RST 7.5. When the I/O device sends an interrupt signal to the CPU, the CPU completes the current instruction and branches to the service routine of the interrupt. After the execution of the ISR, it returns to the main program. In addition to these inputs, the CPU can also be interrupted through its *INTR* input. When an interrupt input signal *INTR* is send to the microprocessor, the CPU then send an interrupt acknowledge signal $\overline{INTA}$ to the external device. In response to this acknowledge signal the op code of the CALL instruction is placed on the data bus. The CPU reads the op code and sends another $\overline{INTA}$ signal. This signal is used to place the low order eight bits address of the CALL instruction on to the data bus. After reading the low order address the CPU sends another $\overline{INTA}$ signal. It then places the high order eight bit address on to the data bus. The CPU then reads and executes the interrupt service routine available in that CALL address. The number of I/O devices that may be used in an interrupt driven environment may be made greater than four if an external device is used. The external device should be capable of accepting interrupt requests and generating unique CALL instructions for the different interrupt inputs. This device will be used to interrupt the microprocessor on the *INTR* line. A programmable interrupt controller (PIC) is such a device (ref. figure 11.1) which accepts interrupt requests from a number of I/O devices, resolves the priority of servicing the requests, and issues an interrupt on the *INTR* input of the 8085A as discussed above.

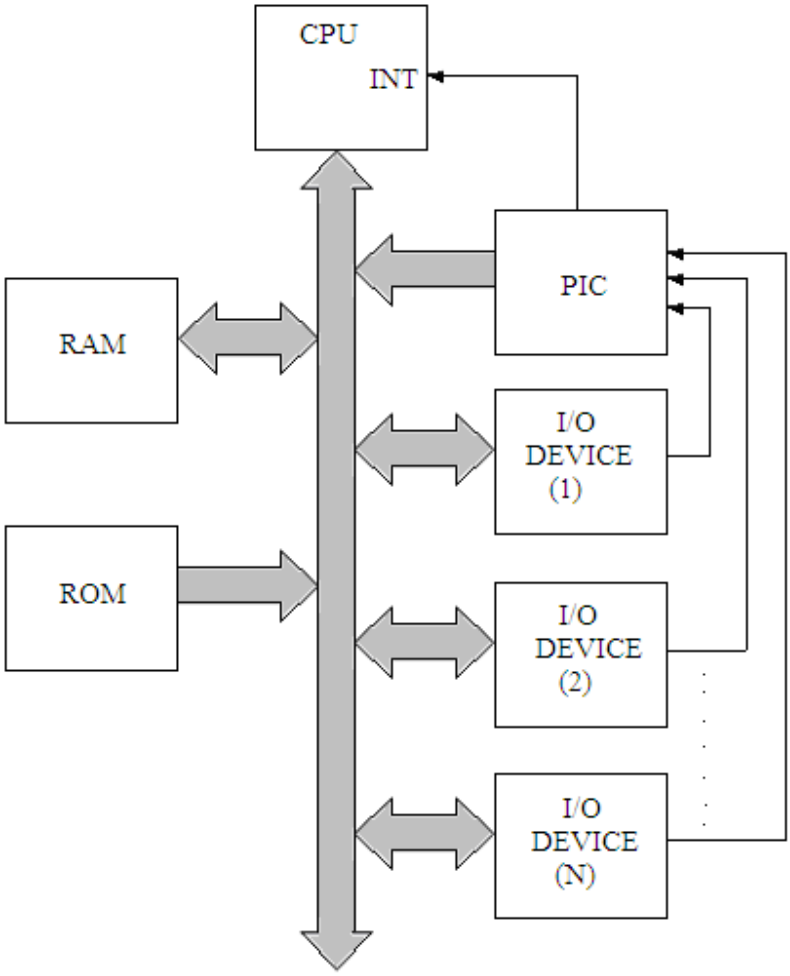


Fig. 11.1

11.2 BLOCK DIAGRAM OF 8259

The 8259 is a programmable interrupt controller which uses NMOS technology. It is available in 28 pin plastic dual in line package (DIP). It requires one power supply of +5 V but does not require any internal or external clock. A single PIC can accept interrupt requests from eight I/O devices, resolve priority among them and communicate to the microprocessor. Interrupt requests from all the I/O devices can individually be masked and a suitable priority mode can be selected by programming. Built in expandability has also been provided to cascade 9 such Programmable Interrupt Controller devices (8259s) to serve up to 64 I/O devices. Figure 11.2 shows the pin diagram of this IC.

The description of the pins of 8259 programmable interrupt controller is given as:

Pin No. 1: This pin is chip select terminal ($\overline{CS}$). It is active low. When a low signal is applied to this terminal, the device is chosen to work.

Pin No. 2: This is write input terminal ($\overline{WR}$), which is also active low. A low to this input enables the CPU to write Initialization Control Word (ICW) and Operation Command Word (OCW) to the 8259A.

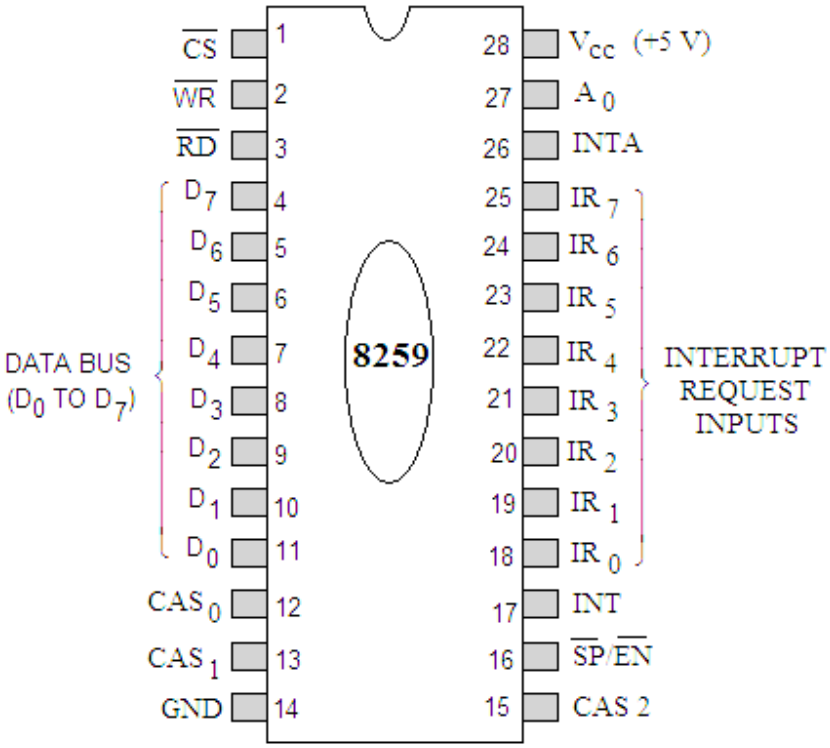

Fig. 11.2

Pin No. 3: This is read input terminal ($\overline{RD}$). A low to this pin enables the 8259A to send the status of the Interrupt Request Register (IRR), In Service Register (ISR), the Interrupt Mask Register (IMR) or the BCD of the interrupt level on the data bus.

Pin Nos. 4-11: These pins (D_0 to D_7) form the bidirectional data bus to be connected to the data bus of the system.

Pin Nos. 12, 13 &15: These pins (CS_0 to CS_2) are known as cascade lines. These lines are used to cascade a number of 8259A.

Pin No. 14: This is a common ground terminal to be connected to the common terminal of the system or the supply.

Pin No. 16: This is slave program/enable buffer ($\overline{SP}/\overline{EN}$). As already discussed more than one 8259A can be used with the system to expand the priority interrupt schemes up to 64 levels. In such cases one 8259A acts as the master and the others act as slaves. A high on this pin designates the 8259A as the master and a low to this pin designates as slave.

Pin No. 17: This is an interrupt output terminal (INT) to be directly connected to the interrupt terminal (INTR) of the CPU. When an interrupt signals is applied to the any of the interrupt request terminals of the 8259, an INT signal is generated for the CPU.

Pin Nos. 18 to 25: These are 8 interrupt request inputs (IR_0 to IR_7).

Pin No. 26: This is an interrupt acknowledge input signal ($\overline{INTA}$), connected to the $\overline{INTA}$ terminal of the CPU. A low acknowledgement signal is sent by the CPU to the 8259, whenever CPU receives an interrupt signal.

Pin No.27: This pin A_0 is the input signal used in conjunction with the signals $\overline{WR}$ and $\overline{RD}$ to write the commands into the various status registers of the device. This terminal can directly be connected to one of the address lines.

Pin No. 28: This is supply pin ($+V_{CC}$) connected to the positive 5 volts.

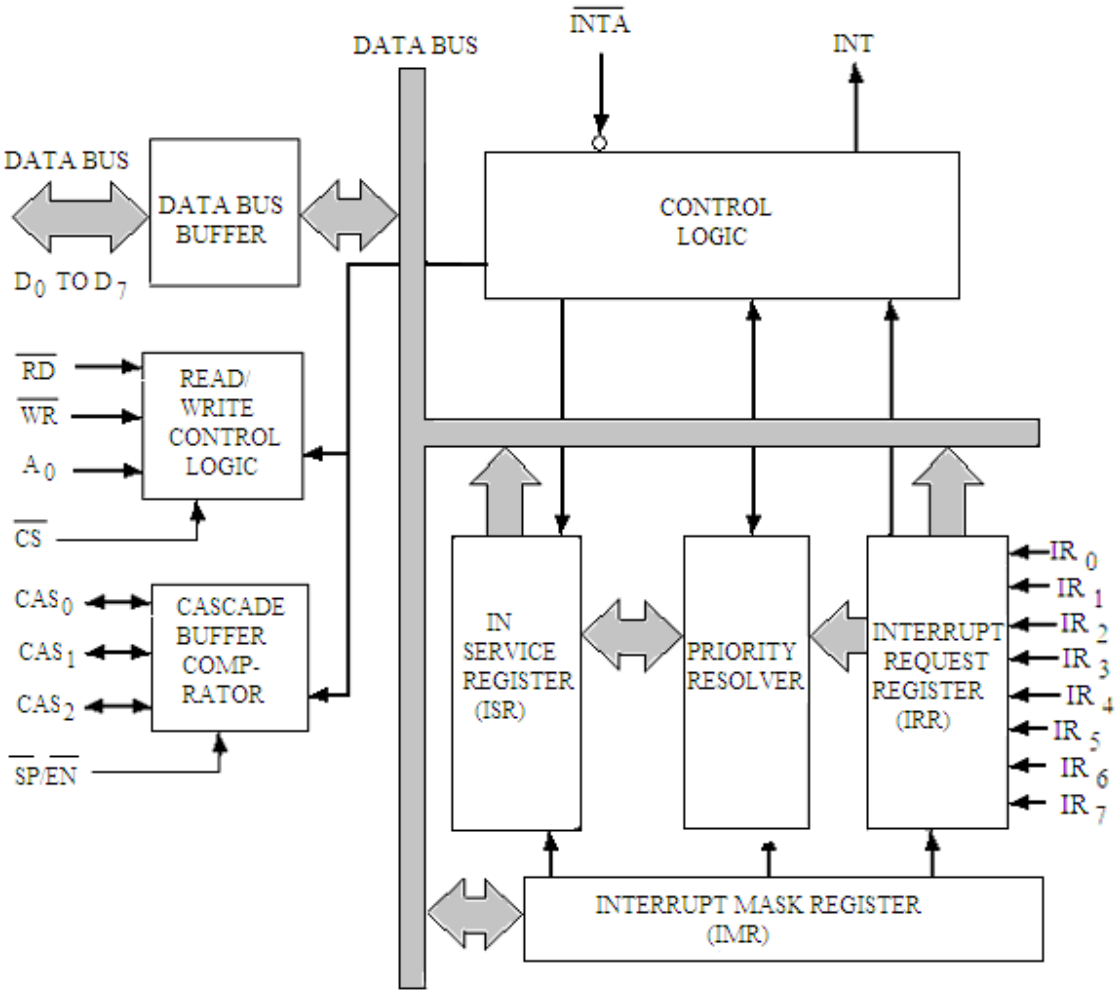

Fig. 11.3

Figure 11.3 shows the internal block diagram of the 8259A. The 8259A contains the following four sections:

1. Interrupt and Control Logic Section
2. Data Bus Buffer
3. Read/Write Control Logic Section
4. Cascade Buffer/Comparator Section

1. Interrupt and Control Logic Section

This section contains the following five sections:

- Interrupt Request Register (IRR)
- In-Service Register (ISR)
- Priority Resolver
- Interrupt Mask Register (IMR)
- Control Logic Section

Interrupt Request Register (IRR)

The interrupt request register (IRR) is used to store all the interrupt levels which are requesting services. It has 8-interrupt lines (IR_0 to IR_7). When any of these lines become high, the corresponding mask bit is checked and if it enabled, then the corresponding bit in the interrupt request register (IRR) is set.

In-Service Register (ISR)

The in-service register (ISR) is used to store information of all the interrupt levels which are currently being serviced.

Priority Resolver

This block of Interrupt and Control Logic Section determines the priorities of the bits set in the IRR. This block determines the priorities as dictated by the priority mode set by the Operation Command Words (OCWs). The bit corresponding to the highest priority interrupt is set in the ISR during the $\overline{INTA}$ input. It is a priority interrupt controller, this means, even while executing an interrupt, it will accept and service a higher priority; but it will reject a lower priority interrupt. The priority resolver does the job of judging whether to allow another interrupt to be executed in the middle of executing one interrupt service routine.

Interrupt Mask Register (IMR)

The interrupt mask register (IMR) stores the bits of the interrupt lines to be masked. The IMR operates on the ISR. In fact this register can be programmed by an operation command word (OCW) to store the bits of the interrupt lines to be masked. An interrupt which is masked by software will not be recognized and serviced even if it sets the corresponding bit in the IRR.

Control Logic Section

After the interrupt request priorities are resolved by the priority resolver, this block control logic sends an interrupt signal through its *INT* signal to the CPU. This terminal *INT* is connected to the *INTR* terminal of the microprocessor. The microprocessor responds to this request by putting an interrupt acknowledge signal $\overline{INTA}$ to the input terminal $\overline{INTA}$ of the 8259A. The PIC then places the op code of CALL instruction on the data bus. This is read by CPU, it places two additional $\overline{INTA}$ signals on the data bus. When the CPU receives the $\overline{INTA}$ signal out of these two additional $\overline{INTA}$ signals, it places the low order byte of the CALL address on the data bus. After receiving the last $\overline{INTA}$ signal, it places the high order byte of the CALL address on the data bus. The CALL address is the vector memory location for t he interrupt; this address is placed in the control register during the initialization of 8259.

2. Data Bus Buffer

This is a three state bidirectional 8-bit data bus buffer is used to interface the 8259A to the system data bus. The control words and status information are transferred through this data bus buffer.

3. Read/Write Control Logic Section

The function of this Read/Write Control Logic section is to accept the commands from the CPU. It contains the initialization command word (ICW) registers and the operation command word (OCW) registers which store the various control formats for device operation. This section also accepts Read commands from the CPU to allow the CPU to read status words. The four pins are connected to this block whose functions are given below:

$\overline{CS}$ (Chip Select)

This pin is chip select terminal, which is active low. A low signal to this terminal selects this device to work.

$\overline{WR}$ (Write)

This is write input terminal, which is also active low. A low to this input enables the CPU to write Initialization Control Word (ICW) and Operation Command Word (OCW) to the 8259A.

$\overline{RD}$ (Read)

A low to this pin enables the 8259A to send the status of the Interrupt Request Register (IRR), In Service Register (ISR), the Interrupt Mask Register (IMR) or the BCD of the interrupt level on the data bus.

A_0

This is the input signal used in conjunction with the signals $\overline{WR}$ and $\overline{RD}$ to write the commands into the various status registers of the device. This terminal can directly be connected to one of the address lines.

4. Cascade Buffer/Comparator Section

It is well known that more than one 8259A can be used with the system to expand the priority interrupt schemes up to 64 levels. In such cases one 8259A acts as the master and the others act as slaves. The necessary control signals for cascade operations are generated with this block. A high on the Slave Program/Enable Buffer ($\overline{SP}/\overline{EN}$) pin designates the 8259A as the master and a low to this pin designates as slave. The 8259A

can be set as master or a slave by the $\overline{SP}/\overline{EN}$ pin in the non-buffer mode, or by software in buffer mode of operation. In the non-buffer mode $\overline{SP}/\overline{EN}$ pin is used as an output to enable the data bus buffer of the system. In addition to $\overline{SP}/\overline{EN}$ pin, there are three more pins (CAS_0 – CAS_2) associated with the cascade buffer/comparator section, whose functions are described below:

For a master, these pins (CAS_0 – CAS_2) are outputs, and for slave these are input pins. When 8259 is a master, the CALL op code is generated by the master in response to first $\overline{INTA}$ signal. The address for vector locations will be released by the slave 8259. Every 8259 has the identification code of three bits to CAS_0 – CAS_2 lines so that one out of eight possible slave may be selected by the master. Basically, the slave 8259s accept the identification signals as inputs and compare the code put out by the master with code assigned to them during initialization. The slave thus selected then puts out the address of the interrupt service routine during the two additional $\overline{INTA}$ signals sent by CPU.

11.3 INTERFACING OF 8259A WITH 8085A

Figure 11.4 shows the interfacing connection of 8259A with 8085A microprocessor in I/O mapped I/O mode. The output of address decoder is connected to

the $\overline{CS}$ input of the 8259A. The A_0 line of the IC is directly connected to the address lines of the system. The $\overline{RD}$ and $\overline{WR}$ signals of the IC are connected to $\overline{I/OR}$ and $\overline{I/OW}$ terminals respectively. Further, *INT* terminal of the 8259 is connected to the *INTR* terminal of the processor. The $\overline{INTA}$ output of the processor is connected to the $\overline{INTA}$ terminal of the processor. The terminal $\overline{SP}/\overline{EN}$ is connected to +5 V supply since only one 8259 is used in the system. If many 8259s are cascaded, then this terminal is connected to the ground terminal. The cascaded pins (CAS_0 – CAS_2) are left open. The eight interrupt request pins IR_0-IR_7 are available for the I/O devices to send the interrupt signals. If any of these interrupt request pins are not used, they may be connected to the ground so that the noise pulse can not create any interrupt.

The cascading of many 8259s with the system is shown in figure 11.5. The $\overline{SP}/\overline{EN}$ terminal of the master PIC is connected to + VCC, whereas $\overline{SP}/\overline{EN}$ terminals of all the slave PICs are connected to ground. The *INT* output of each slave PICs are connected to one of the interrupt lines (IR_0-IR_7) of the master 8259 i.e. 8 INT terminals of 8 slave 8259s are connected to 8 interrupt request lines (IR_0-IR_7). When interrupt request line of a slave is activated, the slave PIC in turn activates one of the interrupt request lines of the master 8259, which in turn interrupts the microprocessor. After the $\overline{INTA}$ is received from the microprocessor, the master enables the corresponding CAS_0 – CAS_2 lines to release the vector address on the data bus in the next two $\overline{INTA}$ signals.

The output of the address decoder is connected to the $\overline{CS}$ of the 8259 PIC as shown in figure 11.4. It communicates with the CPU with the bidirectional bus. From this figure 11.4, it is clear that two I/O port addresses F0 H and F1 H are chosen for the 8259 with $A_0 = 0$ and $A_0 = 1$. It may be noted here that each 8259A (interfaced with 8085A) has its own I/O address which is defined by the address decoder.

11.4 VECTORING DATA FORMATS FOR 8259

The eight interrupt levels generate CALLs to eight equally spaced locations in the memory. Through the programming, these locations can be spaced at an interval of 4 or 8 locations. The format of a byte released in response to the first $\overline{INTA}$ for any IR levels is shown in figure 11.6.

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
1	1	0	0	1	1	0	1	CALL CODE = (CD H)

Fig. 11.6

It is the op code for the CALL instruction (CD H). The format of the byte in response to the second $\overline{INTA}$ for different IR level is shown in figure 11.7, the details of which are given in table 11.1(a) and (b). These tables show for both 4 and 8 interval spacing. For spacing interval of four, the 8259 automatically inserts the bits D_0 – D_4 and D_5 – D_7 as specified while programming the 8259 through ICW 1 (first initialization command word, which will be discussed in the next section). For this interval bits D_4-D_2 specify the interrupt's number and the rest two bits D_1-D_0 have been set to 00. However,

for spacing interval of eight, the 8259 automatically inserts the bits $D_0 - D_5$ and $D_6 - D_7$ as specified while programming the 8259 through ICW 1. For the interval of 8, the bits D_5-D_3 specify the interrupt's number and the rest two bits D_2-D_0 have been set to 000.

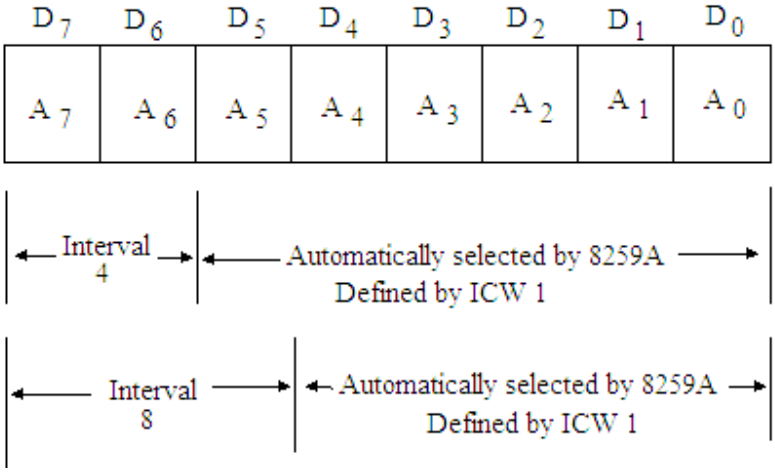

Fig. 11.7

Table 11.1(a)

IR	INTERVAL = 4							
	D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0
7	A_7	A_6	A_5	1	1	1	0	0
6	A_7	A_6	A_5	1	1	0	0	0
5	A_7	A_6	A_5	1	0	1	0	0
4	A_7	A_6	A_5	1	0	0	0	0
3	A_7	A_6	A_5	0	1	1	0	0
2	A_7	A_6	A_5	0	1	0	0	0
1	A_7	A_6	A_5	0	0	1	0	0
0	A_7	A_6	A_5	0	0	0	0	0

Table 11.1(b)

IR	INTERVAL = 8							
	D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0
7	A_7	A_6	1	1	1	0	0	0
6	A_7	A_6	1	1	0	0	0	0
5	A_7	A_6	1	0	1	0	0	0

4	A_7	A_6	1	0	0	0	0	0
3	A_7	A_6	0	1	1	0	0	0
2	A_7	A_6	0	1	0	0	0	0
1	A_7	A_6	0	0	1	0	0	0
0	A_7	A_6	0	0	0	0	0	0

From this table it is clear that the interrupt requests IR_2 and IR_4 for an interval of eight is given by:

	D_5	D_4	D_3	D_2	D_1	D_0
IR2 for an interval of 8 is	0	1	0	0	0	0
IR 4 for an interval of 8 is	1	0	0	0	0	0

Similarly these interrupt requests for an interval of 4 is:

	D_5	D_4	D_3	D_2	D_1	D_0
IR2 for an interval of 4 is		0	1	0	0	0
IR 4 for an interval of 4 is		1	0	0	0	0

Figure 11.8 shows the format of the byte released by the 8259A in response to the third $\overline{INTA}$. The bits D_7-D_0 represent the high order byte of the interrupt vector address (A_8-A_{15}) of all the interrupts; which are specified in ICW 2.

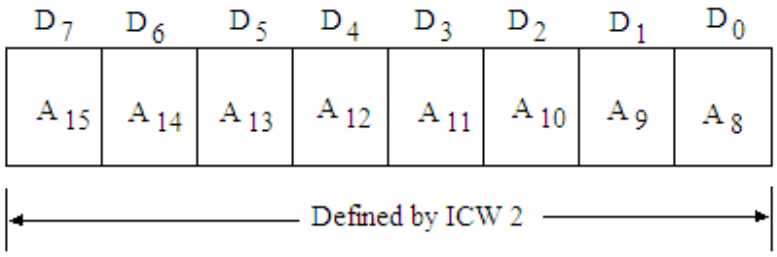

Fig. 11.8

It may be noted here that the 8259A does not allow each interrupt input to have its own independent address. Instead, a base address can be programmed with four or eight interval spacing as discussed above. For example, if the base address is 0100 H and the interval spacing is four, then eight restart locations will exist as shown in table 11.2. Normally, instructions to jump to the appropriate interrupt service routine would be stored in these locations and the 32 bytes of memory from 0100 H to 011F H referred to as jump table.

Table 11.2

Interrupt request	Restart address
IR0	0100 H
IR1	0104 H
IR2	0108 H
IR3	010C H
IR4	0110 H
IR5	0114 H
IR6	0118 H
IR7	011C H

Example 11.1. *For initialization of 8259 the address space available is from E010 H to E040 H. What should be the jump table, if interval spacing between each restart interrupt is four?*

Solution. The address space available for the restart instruction is from E010 H to E040 H, so the restart address for the first interrupt request will start from E020 H, as the five bits of the starting address must be 00000 (ref. Table 11.1a). The jump table is therefore given in table 11.3.

Table 11.3

Interrupt request	Restart address
IR0	E020 H
IR1	E024 H
IR2	E028 H
IR3	E02C H
IR4	E030 H
IR5	E034 H
IR6	E038 H
IR7	E03C H

11.5 INITIALIZATION OF 8259

There are two types of command words in 8259A. These are:

- Initialization Command Words (ICWs)
- Operation Command Words (OCWs)

11.6 INITIALIZATION COMMAND WORDS (ICWs)

There are four command words ICW 1, ICW 2, ICW 3 and ICW 4. The ICW 1 and ICW 2 commands are essential for any 8259A system. However, ICW 3 and ICW 4 commands are optional. The ICW 3 is used if the system has any slave 8259A. The ICW 4 command is used for special operations like special fully nested mode. The microprocessor programs the 8259A by loading the initialization command word (ICWs) and operation command words (OCWs). Each 8259A in the system is first initialized by loading a set of these ICWs in a sequence. The OCWs can be loaded any time after initialization.

Initialization Command Word -1 (ICW 1)

The format for first initialization command word (ICW 1) is shown in figure 11.9. When a byte is sent to the 8259A with $A_0 = 0$, and $D_4 = 1$, it is interpreted as initialization

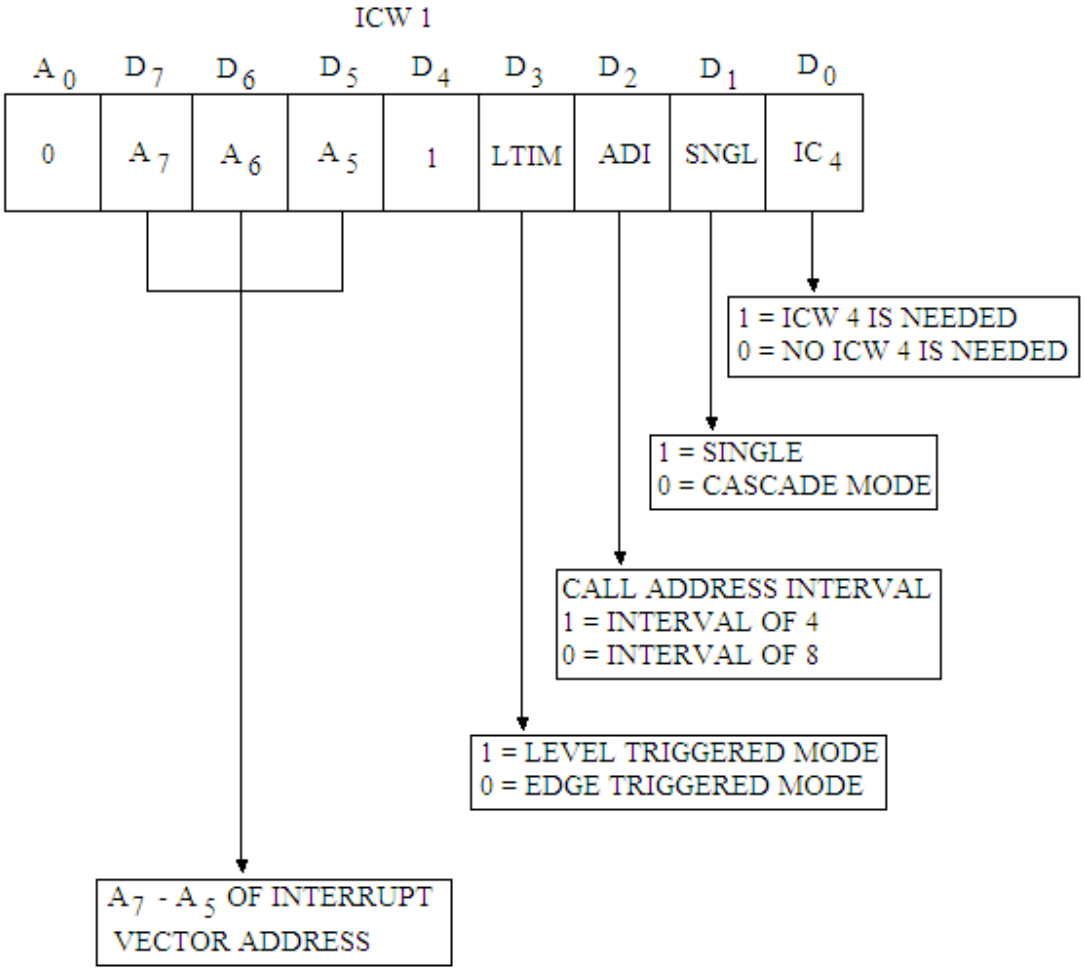

Fig. 11.9

command word-1 (ICW 1). The interpretations of the bits of ICW 1 command word are given below:

Bit D_0 This bit gives the information if the command word ICW 4 is needed.

If $D_0 = 1$, ICW 4 is needed.

If $D_0 = 0$, ICW 4 is not needed i.e. all functions selected by ICW 4 are cleared. This sets the 8259A in the 8085A mode without AEOI (automatic End of Interrupt) and non-buffered operation; and no ICW 4 would be sent with the initialization.

Bit D_1 This bit gives the information if the 8259A is to be used in single or cascaded mode.
If $D_1 = 1$, single 8259A is used and no slave 8259A is used.
If $D_1 = 0$, 8259A is used in cascaded mode.

Bit D_2 This bit gives the information about vector address**.**

If D_2 = 1, Interval for vector address is 4.

If D_2 = 0, Interval for vector address is 8.

Bit D_3 The bit D_3 gives the information about interrupt request inputs whether it is edge triggered or level triggered.
If D_3 = 1, Interrupt request input is level triggered.
If D_3 = 0, Interrupt request input is edge triggered.

Bit D_4 This bit is 1 for ICW 1, as discussed earlier.

Bits D_5 to D_7 These bits give the interrupt vector address (for 8085A only) i.e. these are address bits of the CALL instruction.

Initialization Command Word -2 (ICW 2)

A write command following ICW 1, with A0 = 0, is interpreted as ICW 2. The format for this command word is shown in figure 11.10. This gives information regarding Interrupt Vector Address. The bits D_7-D_0 represent the high order byte of the interrupt vector address (A_8-A_{15}) for 8085 microprocessor. However, T_7-T_3 represent the vector address for 8086/8088 microprocessors.

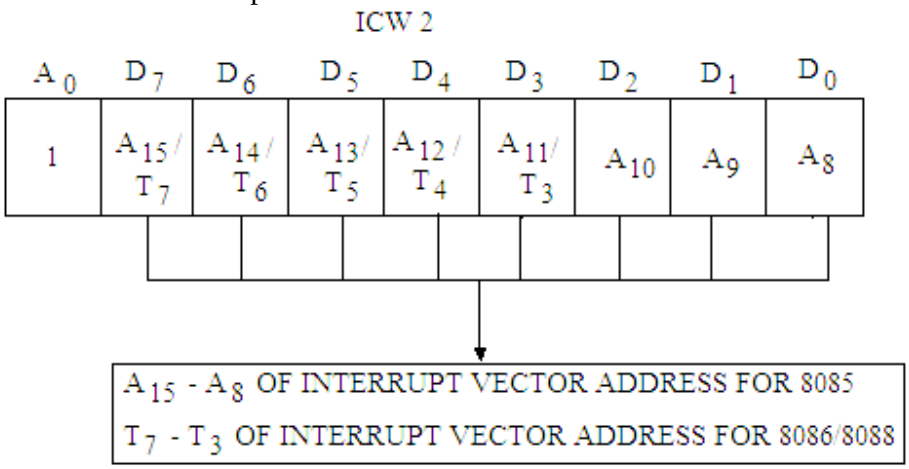

Fig. 11.10

Initialization Sequence of 8259A

Once ICW1 is loaded, the following initialization procedure is carried out internally:

- The edge sense circuit is reset. Since 8259A interrupts are edge sensitive, they are reset.
- IMR is cleared.
- IR7 input is assigned the lowest priority.
- Slave mode address is set to 7.
- Special mask mode is cleared and status read is set to IRR.
- If IC_4 = 0, all functions of ICW4 are set to zero. Master/slave bit is ICW 4 is used in the buffered mode only.

Example 11.2. *Initialize 8259A to interface eight level triggered inputs. The restart address of first interrupt request is E020 H. There is a spacing interval of four byte between each interrupt request. No cascading of 8259A is made. Let the port address is F0 H and F1 H for A_0 = 0 and A_0 = 1 respectively.*

Solution. The single 8259A is to be initialized, so initialization command words ICW 1 and ICW 2 are to be written as given below:

ICW 1

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
A_7	A_6	A_5	1	LTM	ADI	SNGL	IC_4	
0	0	1	1	1	1	1	0	= 3E H

In ICW 1, D_0 = 0 as no ICW 4 is required; D_1 = 1 as single 8259 is used, D_2 = 1 as spacing interval of 4 is required, D_3 = 1 as these are level triggered inputs, D_7 D_6 D_5 are 001 as 20 H is the address of the first interrupt request (**001**0 0000).

ICW 2

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
A_{15}	A_{14}	A_{13}	A_{12}	A_{11}	A_{10}	A_9	A_8	
1	1	1	0	0	0	0	0	= E0 H

ICW 2 gives the address E0 H (base address) 1110 0000.

Program:

```
MVI   A, 3E H      ; ICW 1 code is loaded to acc.
OUT   F0 H         ; F0 H is the port address for A0 = 0.
MVI   A, E0 H      ; Base address is given by ICW 2.
OUT   F1 H         ; ICW 2 port address for A0 = 1.
```

Initialization Command Word -3 (ICW 3)

As already discussed, ICW 1 and ICW 2 are compulsory command words in initialized sequence of 8259A where as ICW 3 and ICW 4 are optional. The command word ICW 3 is read only when cascading of 8259s is used, which is denoted by SNGL (Bit D_1) of ICW 1. The ICW 3 is further classified into following two modes:

Master Mode ICW 3

Slave Mode ICW 3.

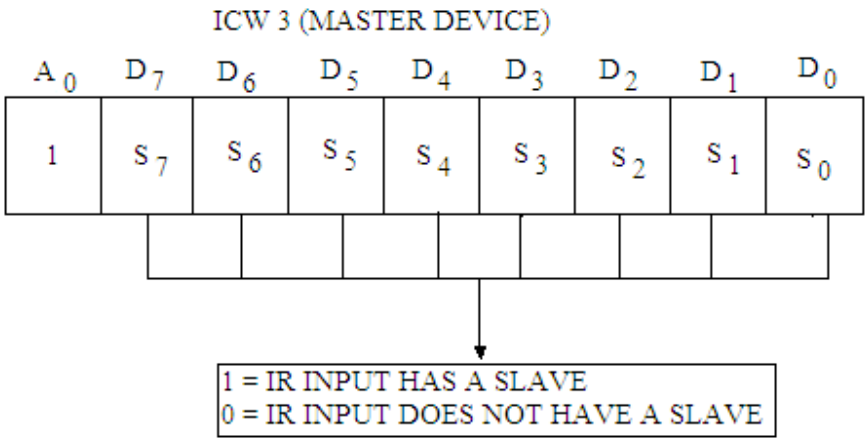

Fig. 11.11

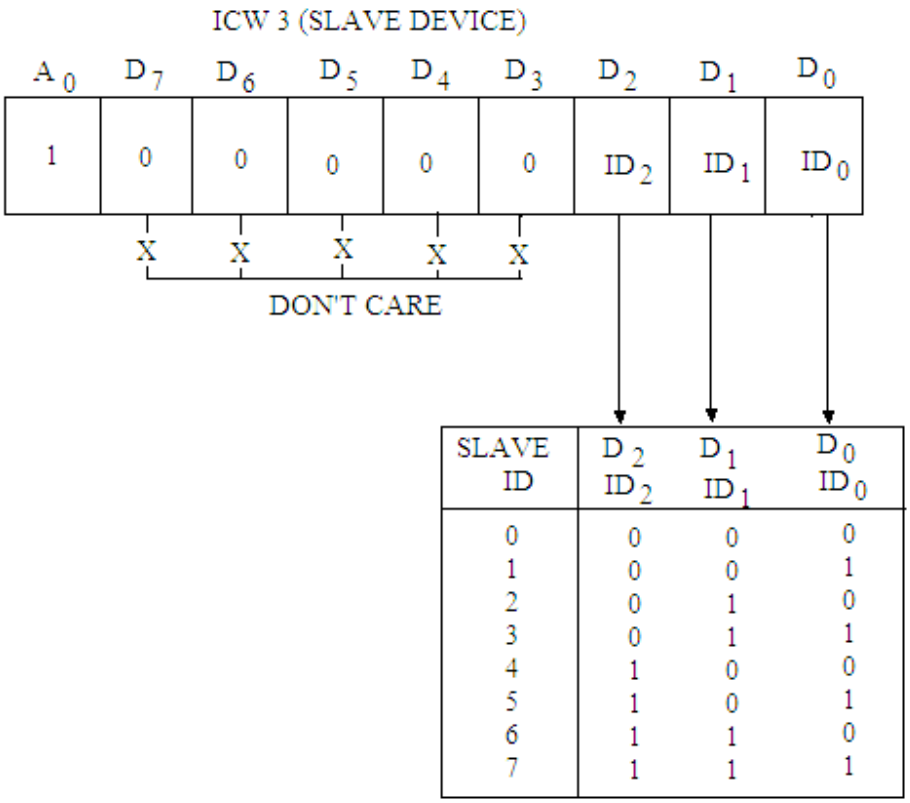
The ICW 3 in Master and Slave modes are shown in figure 11.11 and 11.12 respectively. Each bit in ICW 3 of master mode is used to specify whether it has a slave 8259 attached to its corresponding interrupt request (IRQ) inputs. Suppose S_0 bit is 1. It indicates that 8259 is connected to interrupt request lines IR_0. The command word will be loaded to the 8 bit register and the functions of this register are:

- In the master mode (either when $\overline{SP}/\overline{EN}$ is high, or in buffered mode when M/S = 1 in ICW 4) a 1 set for each slave in the system. The master then will release byte 1 of the CALL sequence and will enable the corresponding slave to release byte 2 and byte 3 through the cascaded lines.
- In the slave mode (either when $\overline{SP}/\overline{EN}$ is low or if BUF = 1 and M/S = 0 in ICW 4) bits D_2-D_0 identify the slave. The slave compares its cascade inputs with these bits and if they are equal, bytes 2 and 3 of the CALL sequence are released by it on the data bus.



SLAVE ID	D_2 ID_2	D_1 ID_1	D_0 ID_0
0	0	0	0
1	0	0	1
2	0	1	0
3	0	1	1

Fig. 11.12

Initialization Command Word -4 (ICW 4)

This command word is loaded only if IC_4 bit of the command word ICW 1 is 1. That is if IC_4 = 1 (of ICW 1) then command word -4 (ICW 4) is used otherwise it is

neglected. The format of this command word is shown in figure 11.13. The bits of this command word identify the following operations:

μPM — This specifies if 8080/8085A or 8086/8088 operation environment is used.
If μPM = 1, 8086/8088 microprocessor operation is selected.
If μPM = 0, then the 8080/8085A operation is selected.

AEOI — If this bit is 1, then the automatic end of interrupt mode is selected, otherwise normal end of interrupt mode.

M/S — If M/S = 1, then 8259A is master.
If M/s = 0, then 8259A is slave.
If BUF = 0, then M/S bit is neglected.

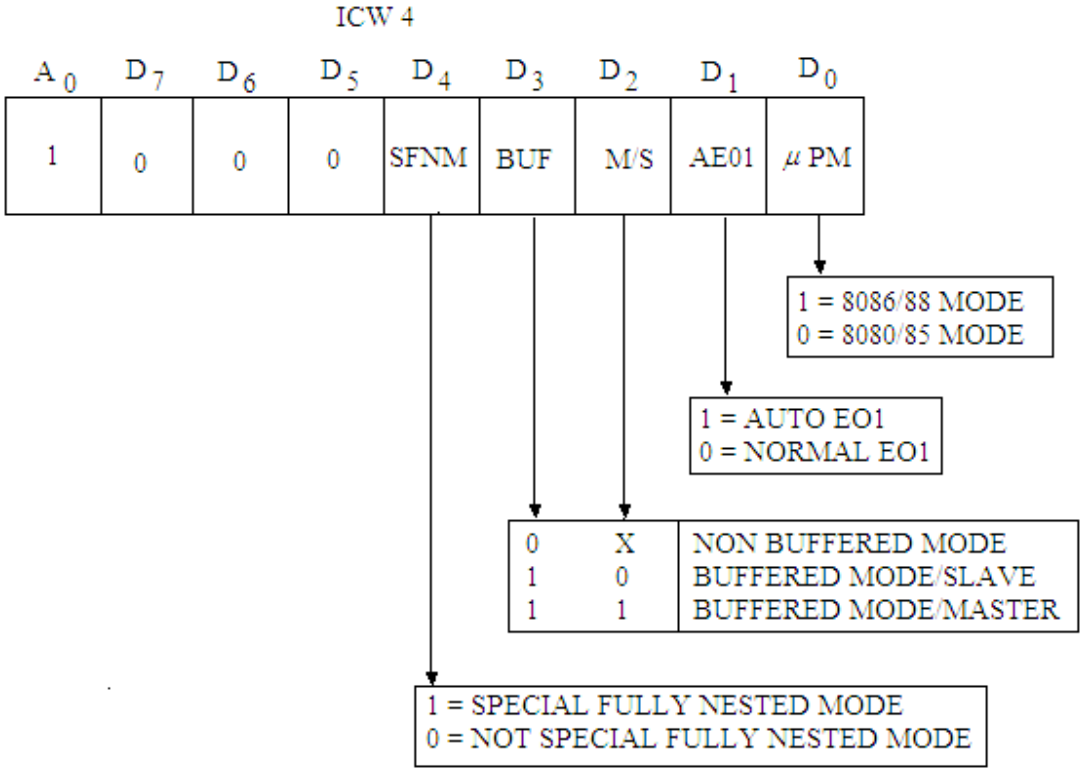

Fig. 11.13

BUF — If BUF = 1, then buffered mode is selected. In buffered mode $\overline{SP}/\overline{EN}$ acts as enable output and Master/Slave is determined by M/S bit of ISW 4.

SFNM — If SFNM = 1, then fully nested mode is selected.
If SFNM = 0, then fully nested mode is not selected.

Figure 11.14 shows the flow chart for the initialization of 8259A.

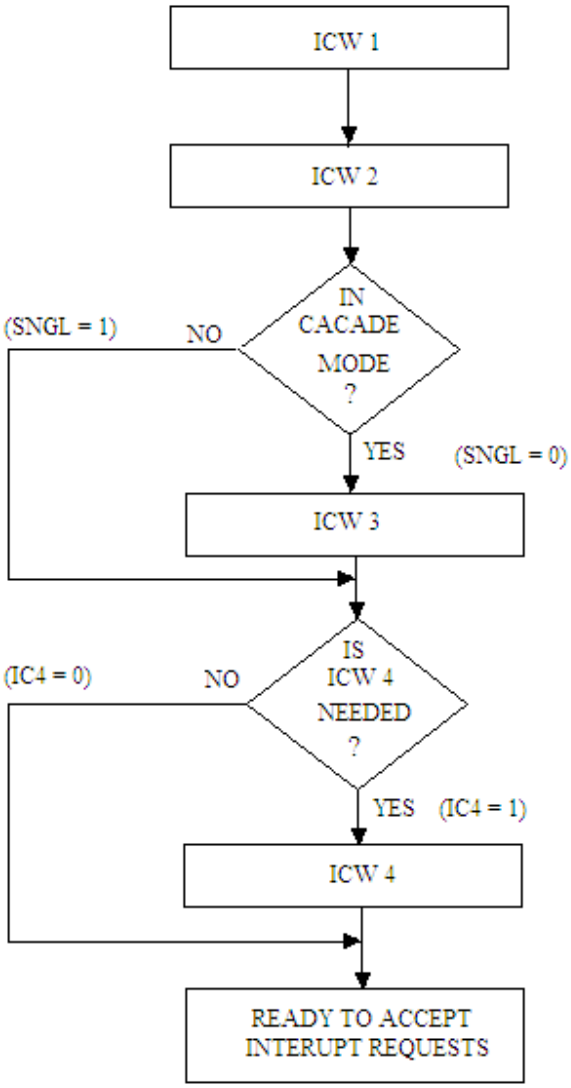

Fig. 11.14

11.7 OPERATION COMMAND WORDS (OCWs)

Once 8259A is initialized using initialization command words (ICWs), the 8259 is ready to accept interrupt requests. For this purpose, different operation command words (OCWs) are loaded in to operation command word registers. There are three operation command words (OCWs) namely: OCW 1, OCW 2 and OCW 3. Now the discussion will made of the operation command words.

Operation Command Word-1 (OCW 1)

This operation command word is written to mask or unmask an interrupt request input. The format for OCW 1 is shown in figure 11.15. For this word A_0 must be high. In this format it is clear if M = 0, then the particular interrupt request is to be unmasked or enabled, however, if M = 1, it is masked or inhibited.

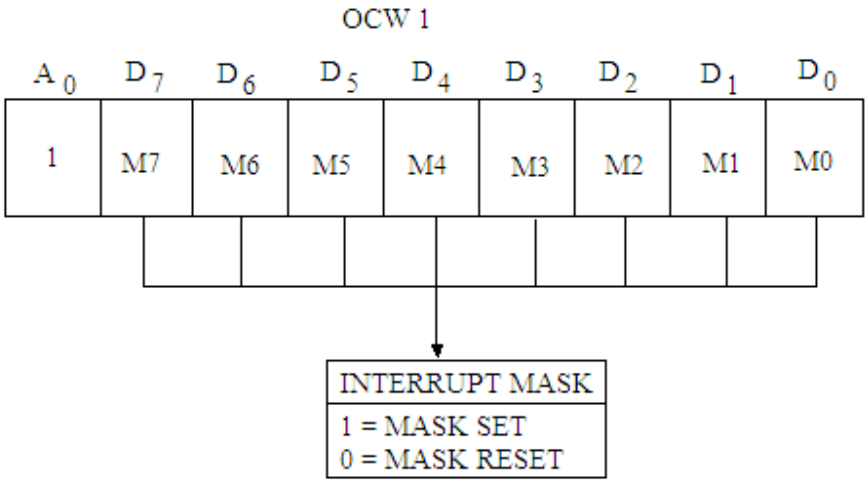

Fig. 11.15

For example, in order to enable the interrupts IR6, IR4 and IR1 then the bit pattern of this operation command word will be:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0
0	1	0	1	0	0	1	0

Operation Command Word-2 (OCW 2)

A write command with $A_0 = 0$ and $D_4\ D_3 = 0\ 0$ is interpreted as OCW 2, which is used to control the Rotate and End of interrupt mode. This is also called End of Interrupt Command. The OCW 2 is mainly used to reset a bit in the in service register (ISR). The format for this operation command word is shown in figure 11.16.

R, SL and EOI – bits control the Rotate, End of interrupt modes and the combination of two. The bits L_2, L_1 and L_0 determine the interrupt level acted upon when the SL bit is active.

When an interrupt request is acknowledged, the 8259A determines the interrupt of highest priority and sets its corresponding bit in the ISR (in service register). The vector address corresponding to this interrupt is then put out. The bit in ISR remains set until an End of Interrupt (EOI) command through OCW 2 is issued by the CPU. At the end of the service routine, the corresponding bit in ISR is to be reset; otherwise other priority interrupts will not interrupt. The 8259A can respond to the interrupt signal of lower priority once the bit of the current IR bit in ISR is reset. The operation command word-2 (OCW 2) can issue the End of Interrupt (EOI) in the following three forms:

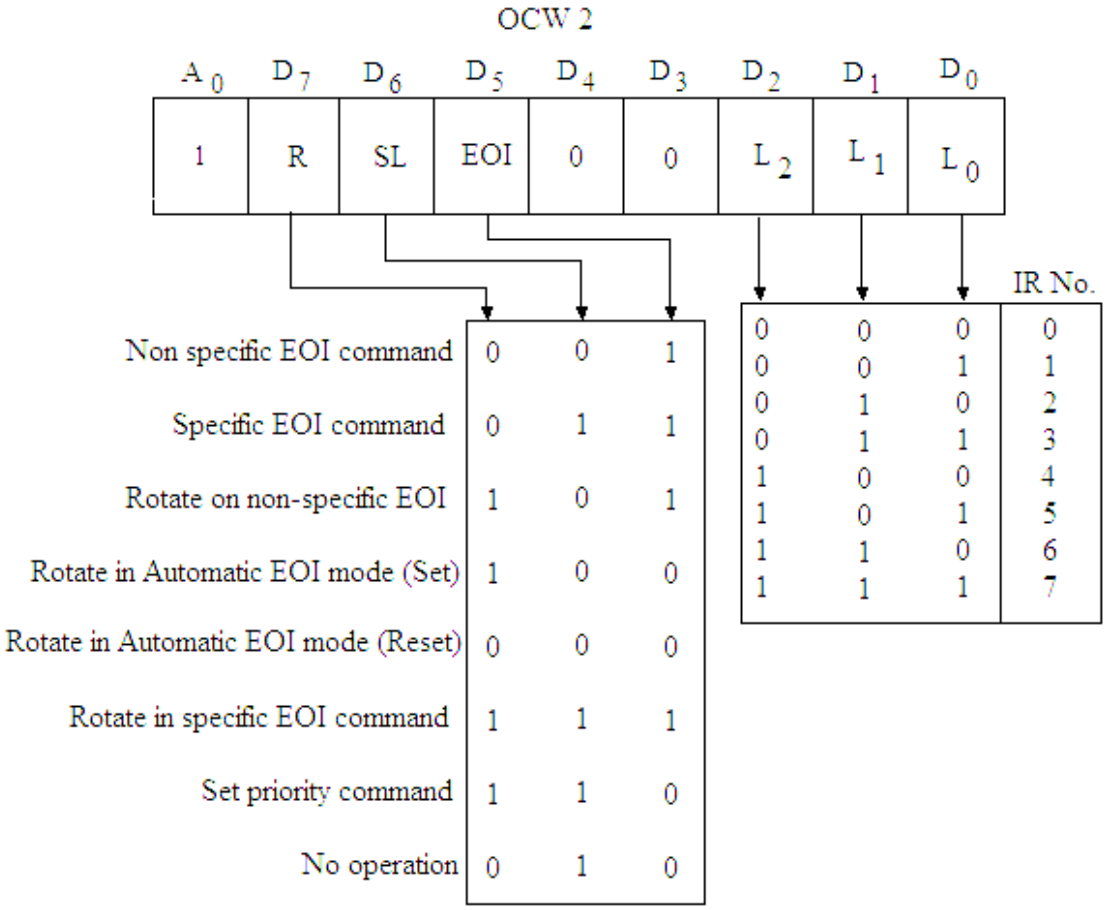

Fig. 11.16

Non Specific EOI Command

In fully nested mode, the highest level in the ISR would necessarily correspond to the last interrupt acknowledged and services. In such a case, a non-specific end of interrupt command (EOI) may be issued by the CPU by the OUT instruction to the 8259A with $A_0 = 0$. For this bit pattern in the format of OCW 2 is given by:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0
0	0	1	0	0	0	0	0

The EOI bit (D_5) of the operation command word-2 (OCW 2) is set to 1. This resets the highest priority in service bit of ISR.

Specific EOI Command

If the fully nested mode is not used, the 8259 may not be able to determine the last interrupt acknowledged. In such case, a specific EOI command will have to be issued by the CPU by the OUT instruction to the 8259A with $A_0 = 0$. For this bit pattern in the format of OCW 2 is given by:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0
0	1	1	0	0	L_2	L_1	L_0

In this bit pattern SL and EOI bits must be set to 1 and the encoded three bit value of the specific bit is written for L_2, L_1, L_0.

For example, in order to reset the bit 3 of the in service register corresponding to IR3, then the bit pattern of the OCW 2 will be given by:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	1	1	0	1	0	0	0	= 68 H

This operation command OCW 2 must be issued twice in case of cascaded mode; one for master and the other for slave.

Automatic End of Interrupt (AEOI)

If this mode is set, no command is necessary to reset the highest priority in service bit in the ISR. The bit in ISR will be reset automatically at the trailing edge of the third $\overline{INTA}$ signal sent by the CPU. This AEOI mode can only be used for a master 8259A and not for a slave. The AEOI is actuated by writing ICW 4 with D_1 bit to 1. At the time of writing the ICW 4, the A_0 line should be 1.

Operation Command Word-3 (OCW 3)

The format for OCW 3 is shown in figure 11.17. This word is used to read the status of the In Service Register (ISR) and Interrupt Request Register (IRR**); and to set or reset the special mask and polled modes.**

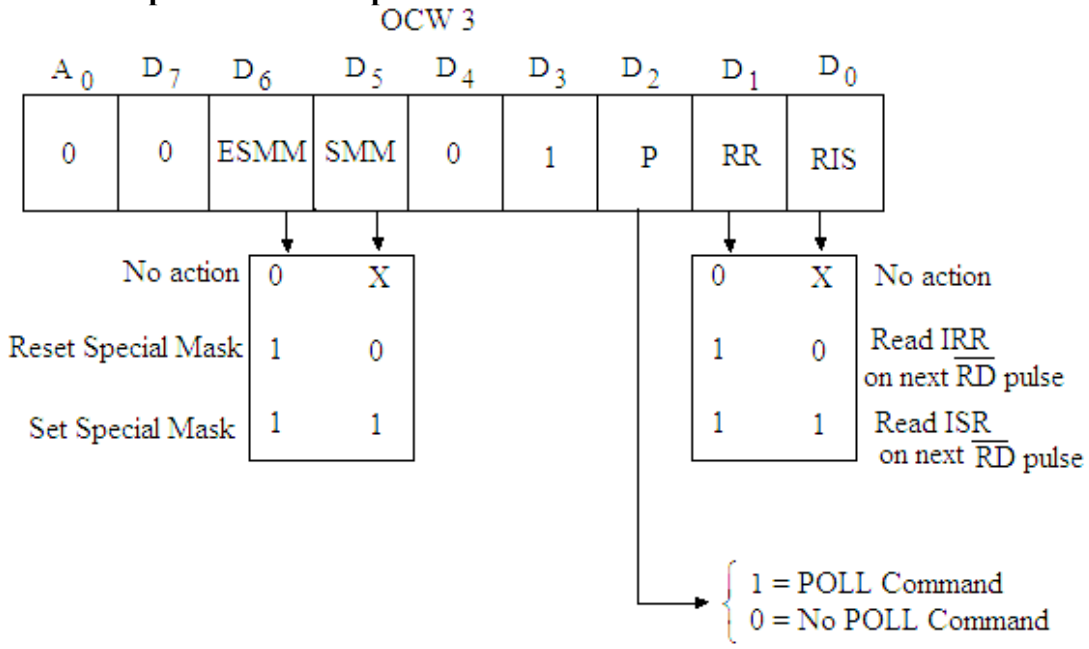

Fig. 11.17

11.8 INTERRUPT MODES OF 8259A

There are following modes of operations of 8259A:

- Fully Nested Mode
- Rotating Priority Mode
- Special Mask Mode
- Polled Mode

11.8.1 Fully Nested Mode (FNM)

The fully nested mode is the general purpose mode in which all interrupt requests are arranged from the highest to lowest priority level. In general, IR_0 has the highest

priority and IR_7 has the lowest priority. This is the default mode setting after initialization. The 8259 continues to operate in FNM until the mode is changed by OCWs. As discussed above, when an interrupt request is acknowledged, the 8259 determines the highest priority interrupt and set its corresponding bit in in-service register (ISR). The vector address corresponding to this interrupt is then put out. The bit in ISR remains set until an End of Interrupt (EOI) command through OCW 2 is issued by the CPU. At the end of the service routine, the corresponding bit in ISR is reset using OCW2.

11.8.2 Rotating Priority Mode

Though by default the priorities of the inputs are assigned as IR0 as the highest priority and IR7 as the lowest priority. But the priorities may be changed using either by automatic rotation or by specific rotation.

Automatic Rotation

This mode is used when all the interrupts are assigned equal priority. In this mode, currently executing interrupt is given the lowest priority after completing its service routine. The next interrupt level is assigned the highest priority. For example, the interrupt request IR_4 and IR_6 are being serviced as it can be read from the status of ISR (figure 11.18). As usual IR_4 is assigned highest priority and will be executed first. When the interrupt service routine for IR_4 is executed, this bit will be reset after EOI command as discussed earlier. Now in this mode of automatic rotation the interrupt IR_4 will have the lowest property and the next interrupt will have the highest priority as shown in figure 11.19.

(IR6, IR4 Being serviced: IR4 is active)

	IS7	IS6	IS5	IS4	IS3	IS2	IS1	IS0
ISR Status	0	1	0	1	0	0	0	0
Priority Status	7	6	5	4	3	2	1	0

Lowest Priority — Highest Priority

Before Rotation

Fig. 11.18

(After EOI from IR4 routine)

	IS7	IS6	IS5	IS4	IS3	IS2	IS1	IS0
ISR Status	0	1	0	0	0	0	0	0
Priority Status	2	1	0	7	6	5	4	3

After Rotation

Fig. 1.19

Automatic rotation mode on an AEOI is set by loading an OCW 2 with R = 1, SL = 0 and EOI = 0 and is reset by loading an OCW 2 with R = 0, SL = 0, and EOI = 0.

Specific Rotation

In this, the programmer can change the priority by programming the lowest priority. This mode is set by CPU by issuing an OUT instruction with A0 = 0 and other bit pattern as given below:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0
1	1	0	0	0	L_2	L_1	L_0

The bits D_2-Do specify the interrupt level that is to be assigned lowest priority. The specific rotation can be accomplished by using the Rotation of specific EOI in OCW2 as R = 1, SL = 1 and EOI = 1.

11.8.3 Special Mask Mode

It may sometimes be desirable to selectively enable lower priority interrupts. Usually, if an EOI command is not given to the 8259A, the in service bit of the last serviced interrupt is not reset. As a result all lower priority interrupts are kept disabled.

This special mask mode can be set by making ESMM and SMM bits as 1 in OCW 3. When a mask bit is set in OCW 1, all further interrupts at that level are inhibited; while interrupts on all other levels that are not masked are enabled. It is thus possible to selectively enable interrupts by programming the mask register. This mode can be cleared by loading an OCW 3 with ESSM = 1 and SMM = 0.

11.8.4 Polled Mode

In this mode the INT output of 8259A is not used. It is either not connected to the INTR input of 8085A or the system interrupts are disabled by software. The 8259A assign the priorities IR_0 through IR_7 inputs and provides a status port that can be polled. The status byte has the form as shown in figure 11.20.

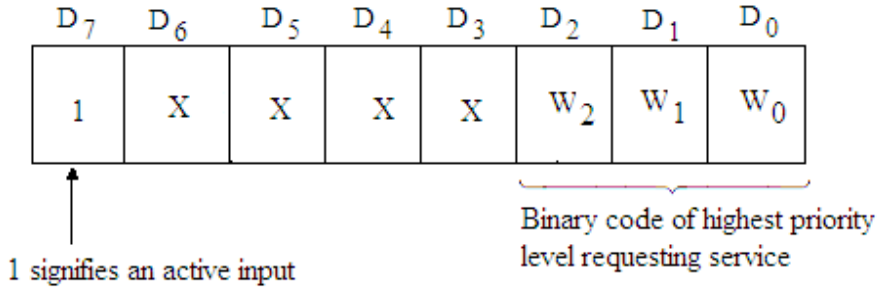

Fig. 11.20

11.9 STATUS READ OPERATION OF 8259

The status of the Interrupt Request Register (IRR), the In-Service Register (ISR) and the Interrupt Mask Register (IMR) of the 8259 may be read by using appropriate read command. These read commands are described below:

Reading IRR Status

Just before reading the IRR (interrupt request register), OCW 3 must be written by making RR (read request) as 1 and RIS (read ISR) as 0. At the time of writing this operation command word, address line A_0 and read signal must be 0. Internally OCW 2 and OCW 3 are recognized by sensing the D_4 and D_3 bits as:

D_4	D_3	
0	0	for OCW 2

1 0 for OCW 3.

After writing the OCW 3, the interrupt request status can be read by using the IN instruction.

IN F0 H if F0 H is the port address with $A_0 = 0$.

Reading ISR Status

For reading ISR status, OCW 3 is initially written with RR = 1 and RIS = 1. The In-service register content can be read using the IN instruction with $A_0 = 0$.

IN F0 H if F0 H is the port address with $A_0 = 0$.

Reading IMR Status

The contents of Interrupt Mask Register (IMR) can be read just by making the A0 = 1. The OCW 3 is not written just before reading.

IN F1 H if F1 H is the port address with $A_0 = 1$.

Example 11.3. *Assume that initialization command words have been written to 8259A (single) having the port address 20 H and 21 H for $A_0 = 0$ and $A_0 = 1$ respectively. Now write proper operation control words for a fully nested priority structure. Mask IR1, IR4 and IR6; enable ISR for a read. What code should be used at the end of interrupt service routine?*

Solution. The initialization commands have already been written. The operation command words are written as:

OCW 1 $A_0 = 1$

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
M7	M6	M5	M4	M3	M2	M1	M0	
0	1	0	1	0	0	1	0	= 52 H

In this OCW 1, M1, M4 and M6 are 1 as IR1, IR4 and IR6 are masked.

For reading ISR status, OCW 3 is initially written with RR = 1 and RIS = 1.

OCW 3

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	0	ESMM	SMM	1	P	RR	RIS	
0	0	0	0	1	0	1	1	= 0B H

In fully nested mode, the highest level in the ISR would necessarily correspond to the last interrupt acknowledged and services. In such a case, a non-specific end of interrupt command (EOI) may be issued by the CPU by the OUT instruction to the 8259A with $A_0 = 0$. For this bit pattern in the format of OCW 2 is given by:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	0	1	0	0	0	0	0	= 20 H

The EOI bit (D_5) of the operation command word-2 (OCW 2) is set to 1. This resets the highest priority in service bit of ISR.

PROGRAM:

```
MVI   A, 52 H     ; OCW 1 is loaded to accumulator.
OUT   21 H        ; 21 H is the port address for A0 = 1.
MVI   A, 0B H     ; OCW 3 is loaded to accumulator to enable the ISR
                    for read.
OUT   20 H        ; 20 H is the port address for A0 = 0,
IN    20 H        ; Read ISR
```

Each interrupt service routine must end by giving the non-specific EOI command which resets in service bit (ISR bit).

```
MVI   A, 20 H
OUT   20 H
RET
```

Example 11.4. *Write Initializing command word to program 8259A (single) with port addresses C0 H and C1 H for A_0 = 0 and A_0 = 1 respectively. Let the starting address of the interrupt request is 7000 H with interval spacing of 4. The interrupts are edge triggered. Interrupts 1 and 3 are masked.*

Solution. The single 8259A is to be initialized, so initialization command words ICW 1 and ICW 2 are to be written as given below:

ICW 1

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
A_7	A_6	A_5	1	LTM	ADI	SNGL	IC_4	
0	0	0	1	0	1	1	0	= 16 H

In ICW 1, D_0 = 0 as no ICW 4 is required; D_1 = 1 as single 8259 is used, D_2 = 1 as spacing interval of 4 is required, D_3 = 0 as these are edge triggered inputs, D_7 D_6 D_5 are 000 as 00 H is the address of the first interrupt request (**000**0 0000).

ICW 2

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
A_{15}	A_{14}	A_{13}	A_{12}	A_{11}	A_{10}	A_9	A_8	
1	1	1	0	0	0	0	0	= E0 H

ICW 2 gives the address 70 H (base address) 0111 0000.

The operation command word is written as:

OCW 1 A_0 =1

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
M7	M6	M5	M4	M3	M2	M1	M0	
0	0	0	0	1	0	1	0	= 0A H

In this OCW 1, M1and M3 are 1 as IR1 and IR3 are masked.

Program:

```
MVI   A, 16 H      ; ICW 1 code is loaded to acc.
OUT   C0 H         ; C0 H is the port address for A0 = 0.
MVI   A, 70 H      ; Base address is given by ICW 2.
OUT   C1 H         ; ICW 2 port address for A0 = 1.
MVI   A, 0A H      ; OCW 1 for masking.
OUT   C1 H         ; Port address for A0 = 1.
```

Example 11.5. *After initializing 8259A with port addresses C0 H and C1 H for A_0 = 0 and A_0 = 1 respectively. Give the instruction sequence to read ISR status and IMR status.*

Solution. After initialization of 8259A , OCW 3 is written with RR = 1 and RIS = 1, to enable reading of ISR status (this is necessary for reading the status of ISR). So OCW 3 is given as:

OCW 3

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	0	ESMM	SMM	1	P	RR	RIS	
0	0	0	0	1	0	1	1	= 0B H

The instruction sequence is then given for the reading the status of ISR and IMR as:

Program:

```
MVI   A, 0B H      ; OCW 3 code is loaded to acc. to enable the
                     reading of ISR status.
OUT   C0 H         ; C0 H is the port address for A0 = 0.
IN    C0 H         ; Read the status of ISR.
IN    C1 H         ; Read the status of IMR.
```

Example 11.6. *An interrupt service routine written for 8259A having port addresses F0 H and F1 H, ends with the instruction sequence given as:*

```
MVI  A, 22 H
OUT  F0 H
RET
```

How does the 8259A interpret these instructions?

Solution. First instruction MVI A, 22 H will show the bit format for OCW 2 is given by:

D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0
0	0	1	0	0	0	1	0

This resets the IR2 in service bit of ISR. This is a non-specific end of interrupt command (EOI) may be issued by the CPU by the OUT instruction to the 8259A with $A_0 = 0$.

PROBLEMS

1. Draw the block diagram of programmable interrupt controller (PIC) 8259A and discuss its various blocks.
2. Describe how the interfacing of 8259A with 8085A microprocessor is done.
3. Discuss how the cascading of 8259A is carried out. How many 8259s may be cascaded? What is the function of master 8259A in the cascading mode?
4. Discuss how initialization of 8259 is carried out.
5. Describe various Initialization command words in 8259A (PIC).
6. What do you understand by operation command words in 8259A? Discuss any one command word.
7. Explain the various interrupt modes of 8259A.
8. Discuss status read operation of 8259A.
9. Explain the vectoring data format of 8259A (PIC).
10. Discuss Rotating Priority mode of operation of 8259A.
11. Initialize 8259A to interface eight edge triggered inputs. The restart address of first interrupt request is 1020 H. There is a spacing interval of four byte between each interrupt request. No cascading of 8259A is made. Let the port address is C0 H and C1 H for $A_0 = 0$ and $A_0 = 1$ respectively.
12. Assume that initialization command words have been written to 8259A(single) having the port address F0 H and F1 H for $A_0 = 0$ and $A_0 = 1$ respectively. Now

write proper operation control words for a fully nested priority structure. Mask IR2, IR3 and IR5; enable ISR for a read. What code should be used at the end of interrupt service routine?

13. Write Initializing command word to program 8259A (single) with port addresses 20 H and 21 H for $A_0 = 0$ and $A_0 = 1$ respectively. Let the starting address of the interrupt request is 8000 H with interval spacing of 4. The interrupts are edge triggered. Interrupts 0 and 4 are masked.
14. Write a non-specific end of interrupt command (EOI) to reset IR3 in service bit of ISR4. Assume the port addresses 20 H and 21 H for 8259.
15. After initializing 8259A with port addresses F0 H and F1 H for $A_0 = 0$ and $A_0 = 1$ respectively. Give the instruction sequence to read ISR status and IMR status.
16. Explain the following initialization instructions:

```
MVI   A, 3E H      ; ICW 1
OUT   80 H         ; Initialize 8259A
MVI   A, E0 H      ; ICW 2
OUT   81 H         ; Initialize 8259A
```

12

Direct Memory Access Controller: 8257

It has already been discussed in an earlier chapter of this book, that the Direct Memory Access (DMA) is the efficient way of transferring the data from the memory to the I/O devices or vice versa without involving the CPU. In DMA operation, the CPU relinquishes the control over the data bus and address bus, so that these can be used for transfer of data between the memory and I/O devices directly. For the data transfer using DMA process, a request to the microprocessor by the I/O device is sent and on receipt of such request, the microprocessor relinquishes the address and data buses and informs the I/O devices of the situation by sending Acknowledge signal. However, in the usual method of data transfer between the I/O devices and the memory, it involves the microprocessor. Each byte is routed through the accumulator, as a result of which it takes lot of time for transferring a large amount of data. For the purpose of DMA operation, a DMA controller is necessary to interface the peripheral to the system. Intel 8257 is a 4-chennel programmable DMA controller used with 8085 and other microprocessors for this mode. In this chapter the details of the DMA controller 8257 will be discussed.

12.1 BLOCK DIAGRAM OF 8257

The 8257 Programmable DMA controller is available in the form of IC dual in line package. It consists of 40 pins and requires +5 volt d.c. supply for its operation. The 8257 enables to interface up to four I/O devices to the microprocessor for the data transfer between the memory and the I/O devices or vice versa using DMA. It has forum DMA channels. Each channel consists of two 16 bit registers. One of these registers holds the address to be used in the next DMA cycle. The other register holds, in the least significant 14 bits, the total number of bytes to be transferred between the memory and peripherals. The two most significant bits of this register are set to indicate the operation to be performed by the device on that channel. A total of 16384 (2^{14} = 16 K) bytes of data may directly be transferred under DMA control without any intervention of the microprocessor.

Figure 12.1 shows the pin diagram of 8257. The pin names of this IC are given below:

D_0-D_7	Data bus	HLDA	HOLD Acknowledge
A0-A7	Address bus	AEN	Address Enable
$\overline{I/OR}$	I/O Read	ADSTB	Address Strobe
$\overline{I/OW}$	I/O Write	TC	Terminal Count
$\overline{MEMR}$	Memory Read	MARK	Modulo 128 MARK
$\overline{MEMW}$	Memory Write	DRQ_0-DRQ_3	DMA Request Input
CLK	Clock Input	$\overline{DACK0}$ - $\overline{DACK3}$	DMA Acknowledge OUT
RESET	RESET Input	$\overline{CS}$	Chip Select
READY	Ready	V_{CC}	+5 V
HRQ	HOLD Request	GND	Ground

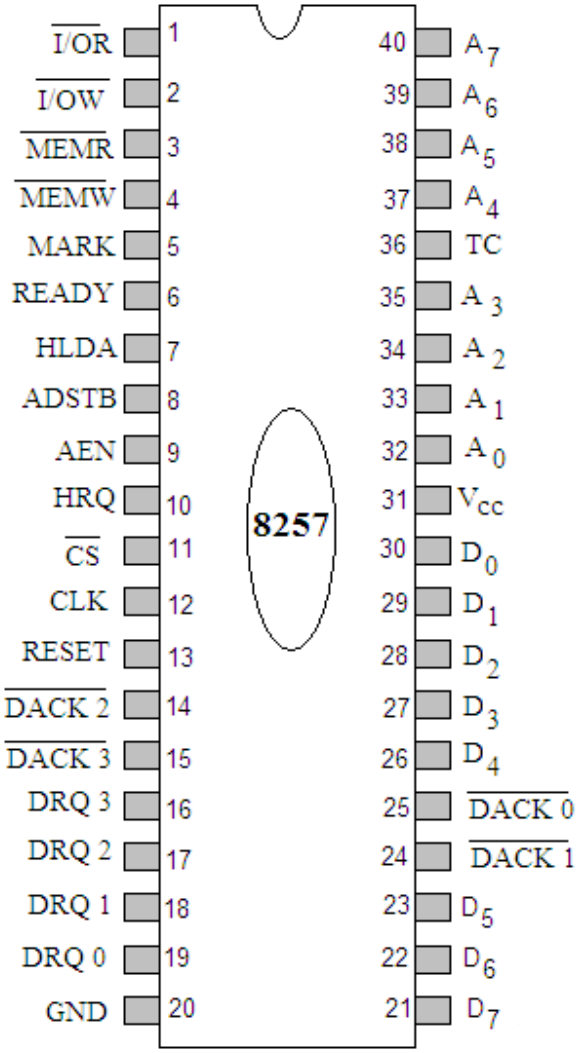

Fig. 12.1

The internal block diagram and schematic diagram of 8257, DMA Controller (DMAC) are shown in figures 12.2 and 12.3 respectively. It contains the following blocks:

- DMA Channels
- Data Bus Buffer
- Read/ Write Logic
- Control Logic
- Mode Set Register
- Status Word Register

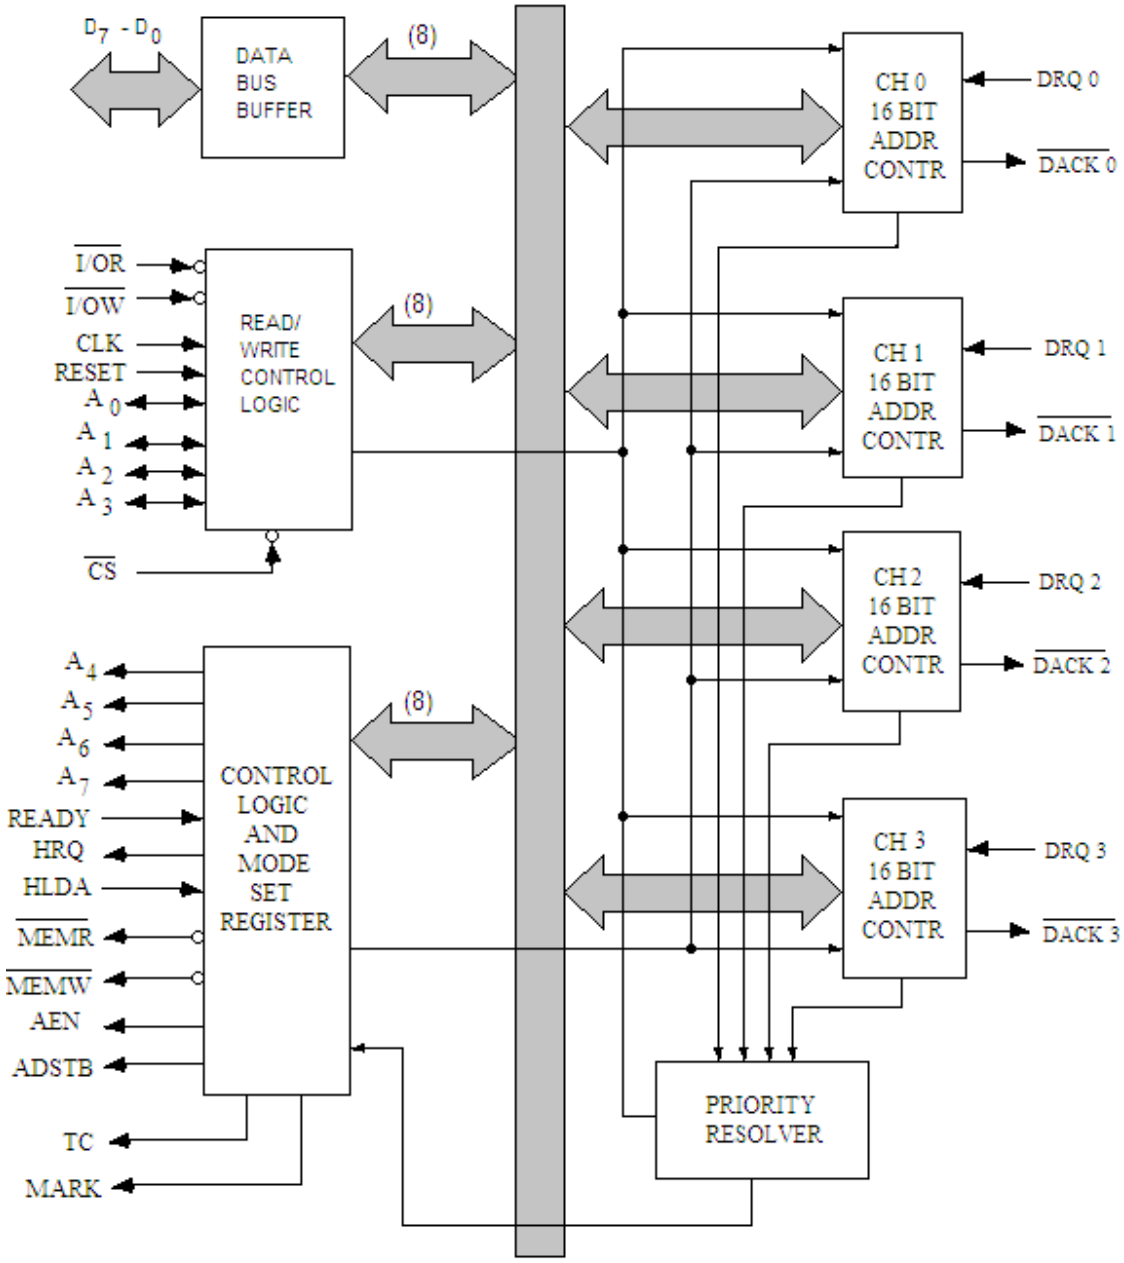

Fig. 12.2

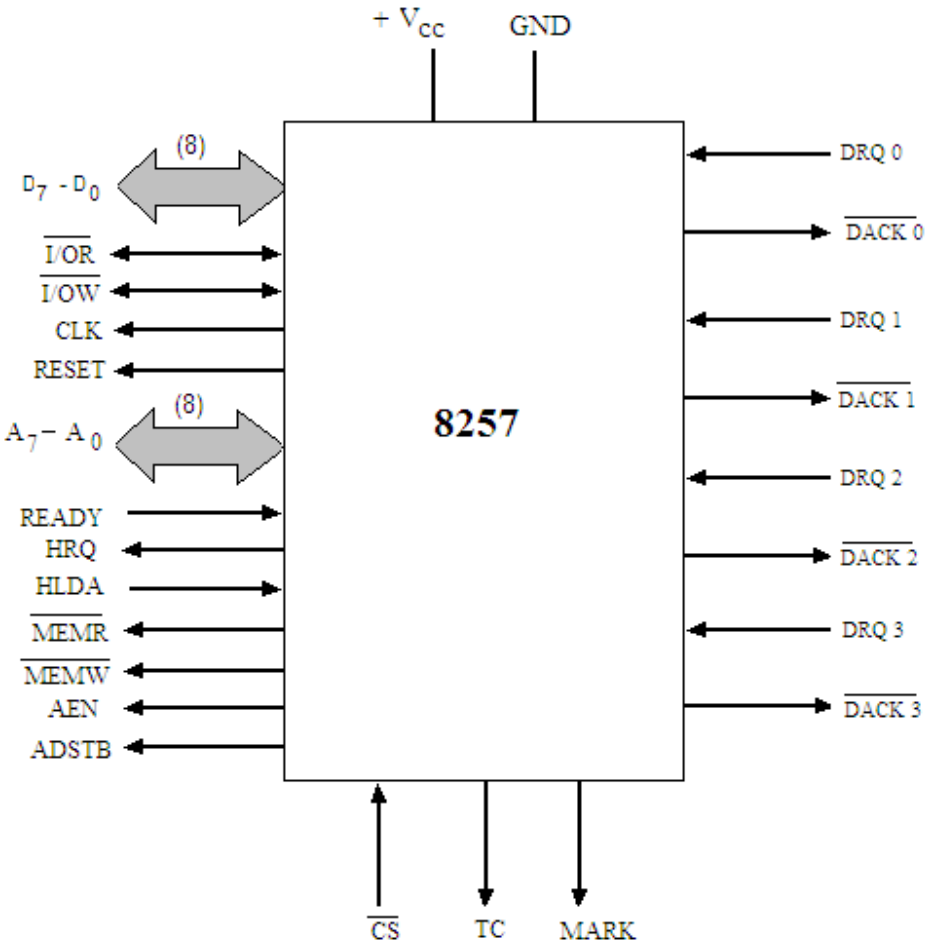

Fig. 12.3

12.1.1 DMA Channels

The 8257 provides 4 channels which can be connected to four separate I/O devices. These channels are designated as Channel 0 (CH-0), Channel 1 (CH-1), Channel 2 (CH-2) and Channel 4 (CH-4). Each of these channels has two 16-bit registers:

DMA Address Register
Terminal Count Register.

DMA Address Register contains the memory address from where the data transfer should begin. This address is loaded by the CPU.

The terminal count register is used to store the number of bytes to be transferred. In this 16 bit register, the least significant 14 bits are used to store the number of bytes to be transferred. In this way one DMA operation can transfer to a maximum of 16 K bytes. The most significant two bits of the terminal register represent the operation to be performed by the device. The operations to be performed are Write, Read and Verify. Figure 12.4 shows the format of the terminal count register of a DMA channel.

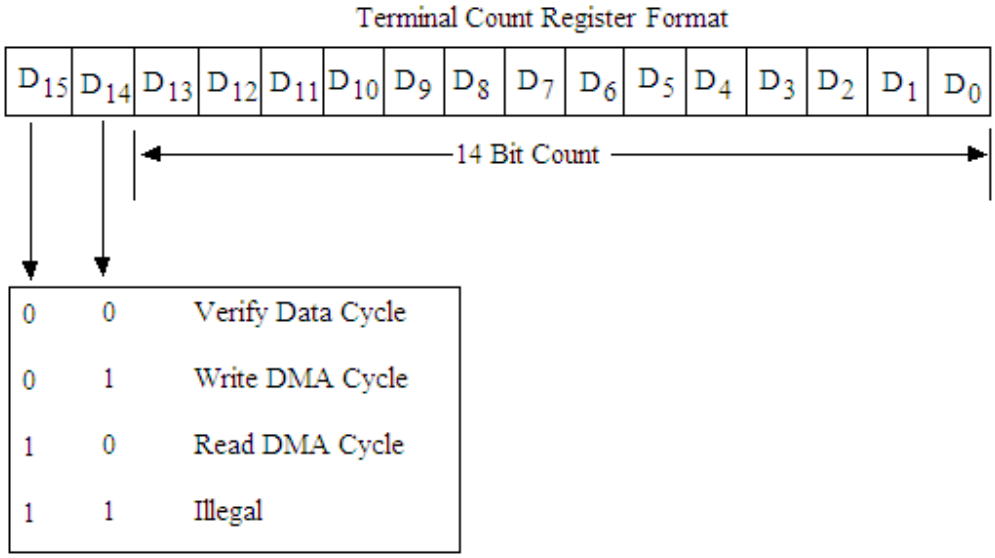

Fig. 12.4

- During DMA write operation, the data is transferred from the peripheral to memory.
- During DMA read operation, the data is transferred from memory to peripheral.
- DMA verify operation does not actually involve the transfer of data.

Each channel has two signals: DMA REQUEST Signal and DMA ACKNOWLEDGE Signal.

DMA REQUEST Signals (DRQ0 – DRQ3):

There are four DMA request signals (DRQ0 – DRQ3) in the 8257 connected one with each channel. Each channel accepts a DMA request through this pin from the peripheral. The DMA controller 8257 has priority facility. The channel 0 (CH 0) has the highest priority and the channel 3 (CH 3) has the lowest priority. As per the priority, a request is generated by the peripheral by making corresponding DRQ line high and holding it high until DMA operation is over.

DMA ACKNOWLEDGE Signals ($\overline{DACK0}$ - $\overline{DACK3}$):

Likewise the DMA request signals, 8257 has the four DMA acknowledge signals ($\overline{DACK0}$ - $\overline{DACK3}$) connected one with each channel. As discussed above, each channel accept a DMA request through it DRQ line from the peripheral. After the receipt of the request channel issues an acknowledge signal through $\overline{DACK}$ output of that channel. It is an active low signal and signifies that the request to be serviced for a DMA cycle is accepted. This signal is made high on completion of the transfer.

12.1.2 Data Bus Buffer

This three state, bidirectional eight bit buffer (D_0-D_7) interfaces the 8257 to the system data bus. When the CPU has the control over the system buses (Slave Mode), the D_0-D_7 pins of the 8257 are used as input pins. The eight bits of data for a DMA address register and terminal count register or the mode set register are received on the data bus. In this slave mode, the CPU can also read eight bits of data at a time from the 16-bit DMA address and terminal count register or from the eight bit status register. However, in the master mode (for DMA cycle, when the CPU relinquishes the control over the control and data buses), the D_0-D_7 pins are used for different purpose. At the beginning of each DMA cycle, most significant bits of DMA address register are put on these pins which are further latched to an external chip 8212 used as latch. These latched values are put on A8-A15 of the system address bus. The D_0-D_7 bus is then released to handle the memory data transfer during the remainder of the DMA cycle.

12.1.3 Read/ Write Logic

When the CPU is programming or reading one of the registers of 8257 (i.e. when the 8257 is in slave mode), the Read/ Write logic accepts the I/ O Read ($\overline{I/OR}$) or I/O Write ($\overline{I/OW}$) signal. It then decodes the least significant four address bits (A_0-A_3), and writes the contents of the data bus into the addressed register (if $\overline{I/OW}$ is active) or places the contents of the addressed register onto the data bus (if $\overline{I/OR}$ is active). During DMA cycle (i.e. when the 8257 is in master mode), the Read/ Write logic generates the I/O Read and Memory Write cycle (DMA Write cycle) and generates the Memory Read and I/O Write Cycle (DMA Read cycle).

$\overline{I/OR}$ (I/O Read)

This is an active low, bidirectional three-state pin. In the slave mode, it is an input signal which allows the 8-bit status register or the upper/lower byte of a 16-bit DMA address register or terminal count register to be read. In the master mode, $\overline{I/OR}$ is a control output, which is used to access data from a peripheral during the DMA write cycle.

$\overline{I/OW}$ (I/O Write)

This is also an active low, bidirectional three-state pin. In the slave mode, it is an input signal which allows the contents of the data bus to be loaded into the 8-bit mode set register or the upper/lower byte of a 16-bit DMA address register or terminal count register. In the master mode, $\overline{I/OW}$ signal is a control output which allows data to be output to a peripheral during a DMA read cycle.

CLK (Clock input)

This input is generally connected to an external clock or to the 8085A CLK output.

RESET (Reset)

This is an active high asynchronous input which disables all DMA channels and clears the mode set register. It also tri states all the control lines.

$\overline{CS}$ (Chip Select)

This is an active low input which enables the I/O Read or I/O write input when the 8257 is being read or programmed in the slave mode. In the master mode, $\overline{CS}$ input is automatically disabled. This is done to prevent the 8257 from selecting itself when it puts out DMA addresses on the address bus.

A_0-A_3 (Address lines)

These least significant four address lines are bidirectional. In the slave mode, they are inputs which select one of the registers to be read or programmed. In the master mode, they are outputs which constitute the least significant four bits of the 16-bit address generated by the 8257.

12.1.4 Control Logic

This block controls the sequence of operations during all DMA cycles by generating the appropriate control signals and the 16-bit address that specifies the memory location to be accessed. The pins associated with the control logic are described below.

A_4-A_7 (Address lines)

These four address lines are the three state output lines. Bits 4-7 of the DMA address register are put on these address lines during the DMA cycles. So, the A_0-A_7 of 8257 carry the least significant byte of DMA address during the execution of a DMA cycle.

READY

This ready input signal can be used by the devices with slow access time in order to insert the wait states during DMA transfer. It has similar function to the Ready input pin of 8085.

HRQ (Hold Request)

This output requests control of the system bus. In systems with only one 8257, this signal will be normally applied the HOLD input of the CPU. HRQ must confirm to specified setup and hold times.

HLDA (Hold Acknowledge)

This is an input from the CPU that informs the 8257 that it has relinquished control of the buses and 8257 may take over the control.

$\overline{MEMR}$ (Memory Read)

This is a three-state active low output which is used to read data from the addressed memory location during DMA Read cycles.

$\overline{MEMW}$ (Memory Write)

This is also three state active low output which is used to write data into the addressed memory location during DMA Write cycles.

ADSTB (Address Strobe)

This is an active high signal which is generated at the beginning of each DMA cycle and has a similar function as that of ALE pin of 8085A.

AEN (Address Enable)

This is an output pin used to float the system data bus and the system control bus. It may also be used to float the system address bus. It may further be used to isolate the 8257 data bus from the system data bus to facilitate the transfer of the 8-bit most significant DMA address bits over the 8257 data I/O pins. When the 8257 is used in an I/O device structure, this AEN output is used to disable the selection of an I/O device when the DMA address is on the address bus. The I/O device selection should be determined by the DMA acknowledge output for the four channels.

TC (Terminal Count)

This is an active high output. When this pin is high it indicates to the currently selected peripheral that the present DMA cycle is the last cycle for this data block. This output goes high, when the contents of the terminal count register of the selected channel are equal to zero. By programming the mode word, a channel can automatically be disabled after its last DMA cycle.

MARK (Modulo 128 Mark)

This active high output notifies the selected peripheral that the current DMA cycle is the 128^{th} cycle since the previous mark output. Mark always occurs at 128 (and all multiples of 128) cycles from the end of the data block. Only if the total umber of DMA cycles (n) is evenly divisible by 128, mark will occur at 128 cycles from the beginning of the data block.

12.1.5 Mode Set Register

The format of Mode Set Register of 8257 is shown in figure 12.5. The control word in the mode set register enables or disables channels and determines other functions. The mode set register can be accessed only for write operation. The various bits in this mode set register enable each of the four DMA channels and four different options for the 8257. The mode set register is cleared by the RESET input, thus disabling all options, inhibiting all channels. This mode set register is also used for programming the 8257 in the following options:

- Rotating Priority
- Extended Write
- TC Stop
- Auto Load

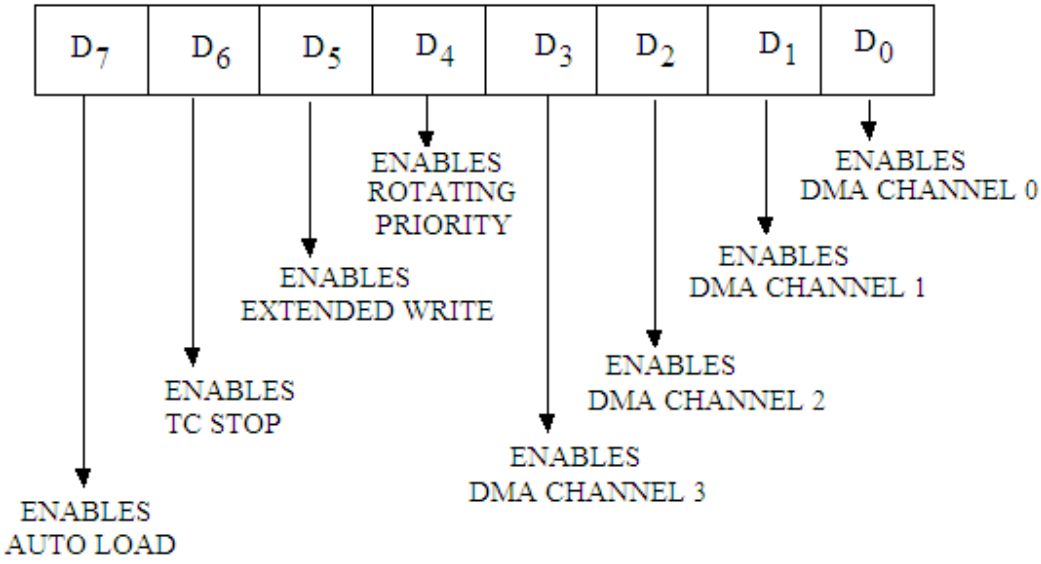

Fig. 12.5

Rotating Priority

The bit 4 (D_4) of the Mode Set Register enables to set the rotating priority mode of the 8257. In the rotating priority mode, the priority of the channels has a circular sequence as shown in figure 12.6. After each DMA cycle the priority of channels has circular sequence. After each DMA cycle, the priority of each channel changes. The channel which had just been serviced will have the lowest priority (Figure 12.7).

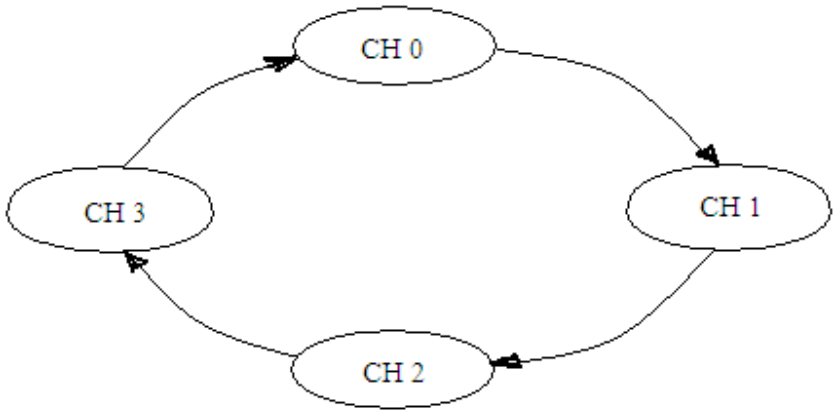

Fig. 12.6

If the rotating priority bit is not set ($D_4 = 0$), each DMA channel has a fixed priority. In the fixed priority mode, channel 0 has the highest priority and the channel 3 has the lowest priority. If the rotating priority bit D_4 is set to 1, the priority of each channel changes after each DMA cycle (not each DMA request). Each channel moves up to the next highest priority assignment, while the channel which has just been serviced moves to the lowest priority assignment.

	CHANNEL JUST SERVED →	CH 0	CH 1	CH 2	CH 3
PRIORITY ASSIGNMENT →	HIGHEST	CH 1	CH 2	CH 3	CH 0
	↕	CH 2	CH 3	CH 0	CH 1
		CH 3	CH 0	CH 1	CH 2
	LOWEST	CH 0	CH 1	CH 2	CH 3

Fig. 12.7

Extended Write

The bit 5 (D_5) of the mode set register is used for extended write option. The data transfer with in microcomputer systems takes place asynchronously which allow the use of various types of memory and I/O devices with different access times. If the device can not be accessed within the specified amount of time, it returns a 'Not Ready' signal on the READY input of the 8257 due to which one or more wait states are inserted in the internal sequencing. Some devices are fast enough to be accessed without the use of wait states. But if they generate their Ready response with the leading edge of the $\overline{I/OW}$ or $\overline{MEMW}$ signal (which generally occurs late in transfer sequence), they would normally cause the 8257 to enter a wait state because it does not receive Ready in time. For systems with these types of devices, the extended write operation provides alternative timing for the I/O and memory write signals which allows the devices to return on early Ready and prevents the unnecessary occurrence of wait states in the 8257.

TC Stop

If the TC stop bit (D_6) of the mode set register is set, a channel is disabled (i.e. its enable bit is reset) after the terminal count (TC) output goes high, thus automatically preventing further DMA operation on that channel. To continue or begin another DMA operation, the enable bit of that channel must be reprogrammed.

If the TC is not set, the occurrence of TC bit output has no effect on the channels enable bits. In that case, it will be responsibility of the peripheral to cease DMA requests in order to terminate a DMA operation.

Auto Load

Bit D_7 of the mode set register enables Auto Load mode. In some cases, it becomes necessary to perform DMA operation repeatedly. In case of a CRT monitor, the data has to repeatedly send to the monitor and this process is called refreshing. With the auto load option, the DMA controller permits such repetitive operation. This bit permits channel 2 to be used for repeat block operation. If the auto load mode is set ($D_7 = 1$), the initial parameters of channel 2 are automatically copied onto channel 3. The channel 2 is programmed with the initial parameters for the first DMA block. When the DMA block of channel 2 is completed, the parameters stored in channel 3 are copied onto channel 2. The channel 2 is then serviced again with the same parameters for repetitive DMA operations. For chaining operation, channel 3 is loaded with a different set of parameters

after channel 2 is loaded; the new parameters are copied onto channel 2 during the update cycle and channel 2 is serviced with a new set of parameters.

12.1.6 Status Word Register

The eight bit status register is shown in figure 12.8. The status register can be read for the status of the terminal counts of the four channels. It also contains the update flag. The count bits (D_0-D_4) of the four channels are set when the terminal count output is high for that channel. The TC bits go low when the status word is read or when the 8257 receives a Reset input. The update flag is reset when:

- 8257 is reset or
- Auto load option in the mode set register is disabled or
- Update cycle gets completed.

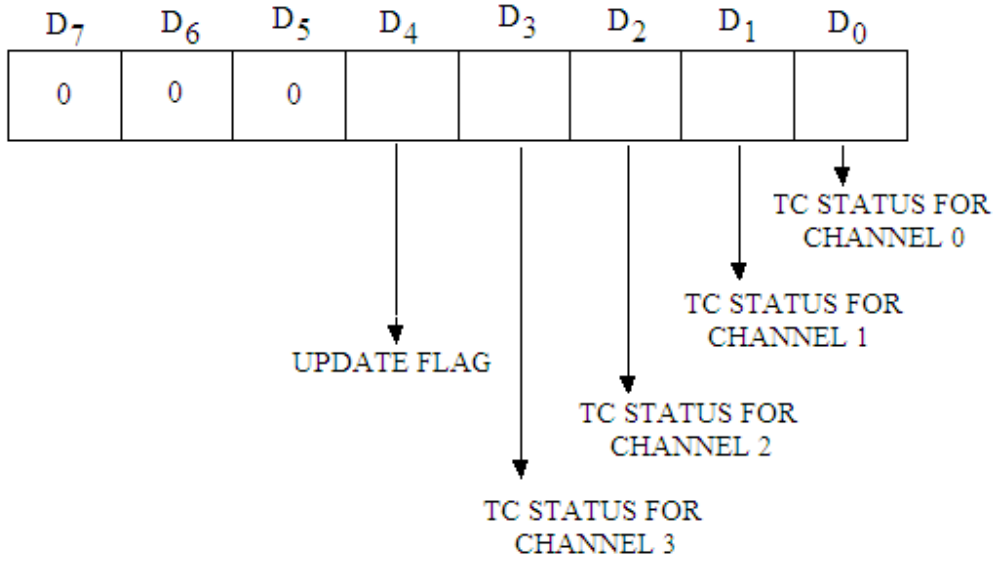

Fig.12.8

12.2 PROGRAMMING OF 8257

As discussed above, there are four pairs of channel registers in 8257; each pair consisting of a 16-bit Address Register and 16 bit Terminal Count Register i.e. one pair for each channel. The 8257 also includes two general registers one 8-bit Mode Set Register and other 8-bit Status Register. These various registers are accessed with the help of four input lines (A_0-A_3) and an internal F/L flip-flop (First/ Last Flip-flop). The address bit 3 (A_3) signifies whether a channel register or the mode set register is being accessed. If A_3 = 0, then channel register is accessed and if A_3 = 1, then the mode set register is accessed. The other three address bits (A_0-A_2) specify which register is to be accessed. When these bits (A_0-A_2) are all zero, the mode set register or status register is being accessed. The 8257 distinguishes between the mode set register (which is write only operation) and the status operation (which is read only operation) by the $\overline{I/OW}$ and $\overline{I/OR}$ inputs respectively. Table 12.1 illustrates the status of A_3 and the control inputs for accessing the various registers. For channel registers, A_2 A_1 specify one of the four channels i.e. for channel 0, it is 00, for channel 1 it is 01, for channel 2 it 01 and for channel 3 it is 11. The bit A_0 specifies whether channel register or terminal count register

is to be accessed. If A_0 = 0, channel register is accessed and if A_0 = 1, terminal count register is accessed. The F/L flip-flop is reset by reset input. This flip-flop toggles for access of the 8257 registers and determines whether upper or lower order byte of a particular register is accessed. It requires that the reading of the address registers or the terminal count registers should be done in pairs; the lower order byte should be accessed first. The addressing of the registers is shown in table 12.2.

Table 12.1

CONTROL INPUT	$\overline{CS}$	$\overline{I/OW}$	$\overline{I/OR}$	A_3
Program Half of a Channel Register	**0**	**0**	**1**	**0**
Read Half of a Channel Register	**0**	**1**	**0**	**0**
Program Mode Set Register	**0**	**0**	**1**	**1**
Read Status Register	**0**	**1**	**0**	**0**

Table 12.2

1	0	0	0	0	0	Status Register (Read Only)

HOB – High order byte
LOB – Low order byte

The microprocessor can either read data from or write data into DMA address register and the terminal count register of each channel of 8257. The status register can be read and mode set register may be programmed. All these operations have been discussed above and carried out during the slave mode of 8257.

If the address decoder circuit for the chip select terminal of DMA controller 8257 shown in figure 12.9 is used, it will give the addresses of DMA registers and terminal count registers of all the four channels along with the address of the mode set registers. These addresses are given in table 12.3.

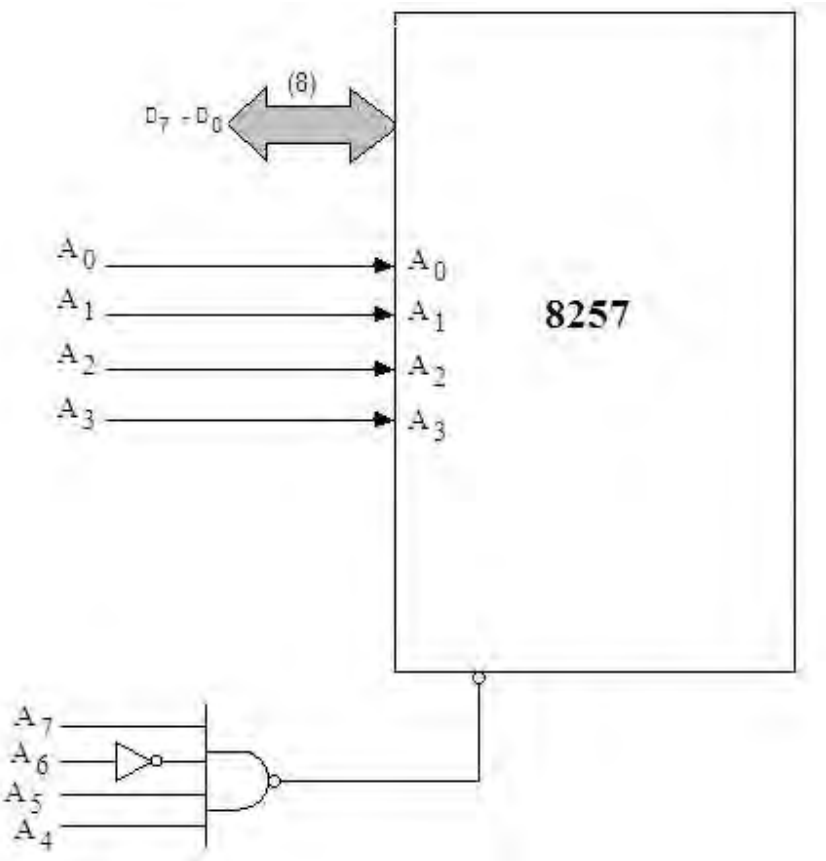

Fig. 12.9

Table 12.3

A_7	A_6	A_5	A_4	A_3	A_2	A_1	A_0	Address	
0	1	0	0	0	0	0	0	70 H	DMA address CH 0
0	1	0	0	0	0	0	1	71 H	TC address CH 0
0	1	0	0	0	0	1	0	72 H	DMA address CH 1
0	1	0	0	0	0	1	1	73 H	TC address CH 1
0	1	0	0	0	1	0	0	74 H	DMA address CH 2
0	1	0	0	0	1	0	1	75 H	TC address CH 2
0	1	0	0	0	1	1	0	76 H	DMA address CH 3
0	1	0	0	0	1	1	1	77 H	TC address CH 3
0	1	0	0	1	0	0	0	78 H	Mode Set Reg addr.

The various registers have to be first initialized and then DMA operation will be started. The steps, to be followed for the DMA operation of 8257 (Master Mode), after its initialization, are given as:

- The I/O device sends a DMA request signal (DRQ) when it is ready to for the data transfer.
- The 8257 sends Hold Request signal (HRQ) high to the processor. It then enables the particular channel.
- In response to HRQ signal, the processor will relinquishes the system busses in the next cycle and will send a Hold Acknowledge (HLDA) signal to the 8257.
- In response to this HLDA signal from the microprocessor, the DMA controller will generate ($\overline{DACK}$) DMA acknowledge signal (active low) through its Control Logic block as an acknowledgement to the requesting peripheral. At the same time the 8257 enables the Address Enable (AEN) signal which disables systems address lines (A0-A7). These address lines becomes the output lines. The low order byte of the memory location is placed of these lines. The address strobe (ADSTB) signal goes high when AEN is high and places higher byte of the memory location generated by 8212 on the address bus A_{15}-A_8.
- The data transfer continues till the terminal count is reached.

12.3 DMA INTERFACING CIRCUIT

Fig. 12.10

8212 is used to de-multiplex the 8085 bus to generate the low order address bus (A_7-A_0). The 8257 has eight address lines, but requires sixteen address lines to address a memory location. The additional eight lines are generated by using the signal ADSTB to strobe a high order memory address into the 8212 from the data bus. This IC is not related to 8085 not to the DMA controller 8257, but only $\overline{DS1}$ is controlled by AEN signal of 8257. The IC 74LS257 is a multiplexer which is used to generate control signals. The $\overline{OE}$ terminal of this multiplexer is also controlled by AEN. The AEN output signal is used to disable (float) the system bus and control bus. This signal is also necessary to switch the 8257 from the slave mode to the master mode. The port addresses of the registers of 8257 are used as discussed above and circuit for the same is given in figure 12.9. The port addressed may be chosen as desired. The second 8212 connected to the DMA controller accepts the data during the DMA operation.

Example 12.1 *Initialize 8257 DMA controller to transfer 2K bytes of data stored in memory locations starting at 2101 H to floppy disk connected to the channel 1 of 8257. Assume that the address of the Mode Set Register is 78 H. The addresses of DMA address register for channel 1 and the Terminal Count Register are 72 H and 73 H respectively.*

Solution. The format for Mode Set register is given below:

D_7	D_6	D_5	D_4	D_3	D_1	D_0	
0	1	0	0	0	1	0	= 42 H
	↓						↓
	Enable						Enable CH 1
	TC stop						

Format for Terminal Count Register is given below:

D_{15}	D_{14}	D_{13}	D_{12}	D_{11}	D_{10}	D_9	D_8	D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
1	0	0	0	0	1	1	1	1	1	1	1	1	1	1	1	= 87FF H

D_{15} and D_{14} as 10 indicate it is memory read operation and D_{10} to D_0 as 11111111111 represents 2 K bytes of data to be transferred to the floppy.

For the initialization of 8257, following steps are to be followed:

- Load mode word in the Mode Set Register.
- Load counts to the terminal count register first LS byte and then MS byte.
- Load starting address of the memory location, from where the data is to be transferred to the floppy disk, to the DMA address register.

The initialization program is therefore given as:

```
MVI A, 42 H      ; Load mode word in the Mode Set Register.
OUT 78 H         ; Address of the Mode Set Register.
MVI A, FF H      ; Load  LS byte of the count in the terminal
                   count register.
OUT 73 H         ; Address of TC register.
```

```
MVI A, 87 H      ; Load MS byte of the count in the terminal
                   count register.
OUT 73 H         ; Address of TC register.
MVI A, 00 H      ; Load the LS byte of the starting address of
                   the memory location from where the data
                   is to be transferred.
OUT 72 H         ; Address of the DMA address register.
MVI A, 21 H      ; Load the MS byte of the starting address of
                   the memory location.
OUT 72 H         ; Address of the DMA address register.
```

Example 12.2 *Initialize 8257 DMA controller to transfer 512 bytes of data from a peripheral to memory locations starting at 3000 H through channel 0. Assume that the address of the Mode Set Register is 28 H. Assume the addresses of DMA address register for channel 0 and the Terminal Count Register are 20 H and 21 H respectively.*

Solution. The format for Mode Set register is given below:

D_7	D_6	D_5	D_4	D_3	D_1	D_0	
0	1	0	0	0	0	1	= 41 H

Enable TC stop

Enable CH 0

Format for Terminal Count Register is given below:

D_{15}	D_{14}	D_{13}	D_{12}	D_{11}	D_{10}	D_9	D_8	D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
0	1	0	0	0	0	0	1	1	1	1	1	1	1	1	1	= 41FF H

D_{15} and D_{14} as 01 indicate it is memory write operation and D_8 to D_0 as 111111111 represents 512 bytes of data to be transferred.

The initialization program is therefore given as:

```
MVI A, 41 H      ; Load mode word in the Mode Set Register.
OUT 28 H         ; Address of the Mode Set Register.
MVI A, FF H      ; Load  LS byte of the count in the terminal
                   count register.
OUT 21 H         ; Address of TC register.
MVI A, 41 H      ; Load MS byte of the count in the terminal
                   count register.
OUT 21 H         ; Address of TC register.
MVI A, 00 H      ; Load the LS byte of the starting address of
                   the memory location from where the data
                   is to be transferred.
OUT 20 H         ; Address of the DMA address register.
MVI A, 30 H      ; Load the MS byte of the starting address of
                   the memory location.
```

```
OUT 20 H          ; Address of the DMA address register.
```

Example 12.3 *An I/O device which is associated with channel 2 of 8257 DMA controller is to be periodically refreshed with 4K bytes of data starting from 2200 H locations. Write the initialization routine for the DMA controller to be operated with auto-load and extended write operations. The addresses of DMA registers and terminal count registers of all the four channels along with the address of the mode set registers are given in table 12.3.*

Solution. The format for Mode Set register is given below:

D_7	D_6	D_5	D_6	D_5	D_4	D_3	D_1	D_0	
1	0	1	0	0	1	1	0	0	= A6 H

D7 = 1 indicates that the auto load enabled, and

D5 = 1 indicates the extended write enabled.

D4 and D3 = 11, indicate that the channel 2 and channel 3 are enabled, which are needed for the auto load and extended write mode.

Format for Terminal Count Register is given below:

D_{15}	D_{14}	D_{13}	D_{12}	D_{11}	D_{10}	D_9	D_8	D_7	D_6	D_5	D_4	D_3	D_2	D_1	D_0	
1	0	0	0	1	1	1	1	1	1	1	1	1	1	1	1	= 8FFF H

D_{15} and D_{14} as 10 indicate it is memory read operation and D_{11} to D_0 as 111111111111 represents 4096 (4K) bytes of data to be transferred.

In this case the starting address of the memory location is to be loaded to both DMA address registers of both channel 2 and channel 3 for auto load and extended write mode.

The initialization program is therefore given as:

```
MVI A, A6 H       ; Load mode word in the Mode Set Register.
OUT 78 H          ; Address of the Mode Set Register.
MVI A, FF H       ; Load  LS byte of the count in the terminal
                    count register of channel 2.
OUT 75 H          ; Address of TC register of channel 2.
MVI A, 8F H       ; Load MS byte of the count in the terminal
                    count register of channel 2.
OUT 75 H          ; Address of TC register of channel 2.
MVI A, FF H       ; Load  MS byte of the count in the terminal
                    count register of channel 3.
OUT 77 H          ; Address of TC register of channel 3.
MVI A, 8F H       ; Load MS byte of the count in the terminal
                    count register of channel 3.
OUT 77 H          ; Address of TC register of channel 3.
MVI A, 00 H       ; Load the LS byte of the starting address of
                    the memory location.
```

```
OUT 74 H        ; Address of the DMA address register
                  channel 2.
MVI A, 22 H     ; Load the MS byte of the starting address of
                  the memory location.
OUT 74 H        ; Address of the DMA address register ch.2.
MVI A, 00 H     ; Load the LS byte of the starting address of
                  the memory location.
OUT 76 H        ; Address of the DMA address register
                  channel 3.
MVI A, 22 H     ; Load the MS byte of the starting address of
                  the memory location.
OUT 76 H        ; Address of the DMA address register ch.3.
```

PROBLEMS

1. What do you understand by Direct Memory Access? What is the use of DMA controller for the data transfer from memory to I/O devices or vice-versa?
2. Draw the block diagram of 8257 DMA controller. Discuss the functions of it blocks.
3. How many I/O devices can be connected with the 8257? How many register are there in 8257? Discuss these registers.
4. Give the format of terminal count register. Discuss the functions of the bits of TC register.
5. What is the function of the Read/ Write Logic block of the 8257 DMA controller?
6. Mention the function of each signal of the control logic block of 8257 DMA controller.
7. What is the function of Mode Set Register of the 8257? How 8257 is programmed in Auto Load option?
8. How 8257 is programmed in Rotating Priority option?
9. Give and discuss the format of the Status Word Register of 8257.
10. How the programming of 8257 DMA controller is done?
11. Give the address decoder circuit for addresses of various registers as C0 H to C8 H. The decoder circuit enables chip select terminal ($\overline{CS}$) of the 8257.
12. What steps are carried out for initialization of 8257?
13. Draw and discuss the interfacing circuit of 8257 with 8085A microprocessor.
14. Initialize 8257 DMA controller to transfer 4K bytes of data stored in memory locations starting at 2501 H to an output device connected to the channel 2 of 8257. Assume that the address of the Mode Set Register is C8 H. The addresses of DMA address register for channel 2 and the Terminal Count Register are C4 H and C5 H respectively.

15. Initialize 8257 DMA controller to transfer 200 bytes of data stored in memory locations starting at 2000 H to an output device connected to the channel 0 of 8257. Assume that the address of the Mode Set Register is 28 H. The addresses of DMA address register for channel 0 and the Terminal Count Register are 20 H and 21 H respectively.

16. The DMA controller 8257 should be initialized as follows:

    DMA channel 2 must be enabled and terminal count stop bit is to be enabled.

    2500 H must be written in DMA address register channel 2.

    500 (decimal) must be written in Terminal counter of channel 2 and D14 and D15 are set for memory read operation.

    Assume the address of the DMA address register for channel 2 is 94 H and the terminal count is 95 H; and the address of the mode set register is 98 H.

17. Initialize 8257 DMA controller to transfer 8K bytes of data from a peripheral to memory locations starting at 21FF H through channel 1. Assume that the address of the Mode Set Register is 98 H. Assume the addresses of DMA address register for channel 1 and the Terminal Count Register are 92 H and 93 H respectively.

18. An I/O device which is associated with channel 2 of 8257 DMA controller is to be periodically refreshed with 1K bytes of data starting from 2500 H locations. Write the initialization routine for the DMA controller to be operated with auto-load and extended write operations. The addresses of DMA registers and terminal count registers of all the four channels are C0 H to C7 H; and the address of the mode set register is CH H.

13

Interfacing Data converters: A/D and D/A Converters

Sometimes the information available for processing in microprocessor based system is in digital form while in most of the cases it is available in analog form. For example, the outputs of digital voltmeter, digital frequency meter, digital clock and calculators etc. are available in digital form but most physical quantities such as temperature, pressure, light, voltage and current etc. gives information in analog form. It is often necessary to convert information in one form to another form for the purpose of interfacing with the system. For example, to design the microprocessor base temperature controller, the temperature of the device obtained from the transducer such as thermocouple or thermister is first converted to the digital form using D/A converter then interfaced with the microprocessor. Similarly, for plotting the output of a system on a curve plotter or X-Y recorder, the digital output is first converted to analog output with the help of digital to analog converter, the output of which drives a servomotor. So analog to digital (A/D) converters or digital to analog (D/A) converters are the interfacing devices with the system. In this chapter various types of A/D and D/A converters and their interfacing with the microprocessor will be discussed.

13.1 DIGITAL TO ANALOG CONVERTER

Digital to Analog (D/A) converter converts the digital information into analog form. The input may be of *n*-bit long having different voltage levels. So in the D/A converters, some method is to be used which can convert this voltage level of *n*-bits to its equivalent analog form. This can be accomplished by using different resistive networks. Following two types of resistive networks are basically used for this purpose:

1. Resistive Divider Network or weighted resistor network
2. Binary Ladder Network or R-2R network

The converter which comprises the resistive divider network is known as Resistive Divider D/A converter and the D/A converter which comprises the binary ladder network is known as Binary Ladder D/A converter. These converters will now be discussed.

13.1.1 Resistive Divider D/A converter

As discussed above, the resistive divider D/A converter consists of a resistive divider network, so before discussing the complete circuit diagram of a resistive divider D/A converter, it is better to understand the working of resistive divider network. The resistive divider network changes each of the *n*-bit digital level into its equivalent analog

output. The discussion will now be made for the method of converting the *n*-bit digital input to its equivalent analog signal. A weight is assigned to each bit of *n*-bit digital input in such a way that the sum of weight must be equal to 1. In general, the binary weight assigned to LSB in an *n*-bit digital input is $\frac{1}{2^n - 1}$. The weights assigned to 2nd LSB, 3rd LSB, 4th LSB and so on are obtained by multiplying the weights of LSB to 2^1(=2), 2^2 (=4), 2^3 (=8)…. respectively. For instance, weights assigned to different bits of 4-bit binary input $b_3\ b_2\ b_1\ b_0$ are:

Weight assigned to LSB (b_0 bit) is $\frac{2^0}{2^4 - 1} = \frac{1}{15}$

Weight assigned to 2nd LSB (b_1 bit) is $\frac{2^1}{2^4 - 1} = \frac{2}{15}$

Weight assigned to 3rd LSB (b_2 bit) is $\frac{2^2}{2^4 - 1} = \frac{4}{15}$

Weight assigned to MSB (b_3 bit) is $\frac{2^3}{2^4 - 1} = \frac{8}{15}$

The sum of weights assigned to each bit of 4-bit digital input is 1 as $\frac{1}{15} + \frac{2}{15} + \frac{4}{15} + \frac{8}{15} = 1$.

In a four bit binary system there will be 16 different possible input combinations, corresponding to which the analog signal will be obtained if it is assumed that a certain reference voltage (V_{REF}) is applied whenever there is a 1 in binary bit. In a 4 bit digital system if V_{REF} =15 volts, the analog voltage available for each combination of binary input should be as given in table 13.1.

Table 13.1

b_3	b_2	b_1	b_0	Weight	Analog Voltage
0	0	0	0	0/15	(0/15)V_{REF} = 0 Volt
0	0	0	1	1/15	(1/15) V_{REF} = 1 Volt
0	0	1	0	2/15	(2/15) V_{REF} = 2 Volt
0	0	1	1	3/15	(3/15) V_{REF} = 3 Volt
0	1	0	0	4/15	(4/15) V_{REF} = 4 Volt
0	1	0	1	5/15	(5/15) V_{REF} = 5 Volt
0	1	1	0	6/15	(6/15) V_{REF} = 6 Volt
0	1	1	1	7/15	(7/15) V_{REF} = 7 Volt
1	0	0	0	8/15	(8/15) V_{REF} = 8 Volt
1	0	0	1	9/15	(9/15) V_{REF} = 9 Volt
1	0	1	0	10/15	(10/15) V_{REF} = 10 Volt
1	0	1	1	11/15	(11/15) V_{REF} = 11 Volt
1	1	0	0	12/15	(12/15) V_{REF} = 12 Volt
1	1	0	1	13/15	(13/15) V_{REF} = 13 Volt
1	1	1	0	14/15	(14/15) V_{REF} = 14 Volt
1	1	1	1	15/15	(15/15) V_{REF} = 15 Volt

So the analog voltage for binary word = (weight of the binary word) x V_{REF}

It may be noted from this table 13.1 that the analog voltage corresponding to binary equivalent is discrete step value as given in figure 13.1. The discrete step is of 1 volt if V_{REF} is assumed to be 15 volts in a four bit digital input. The step voltage (analog) will be dependent on the reference voltage. There will, however, be 2^n steps in *n*-bit digital system.

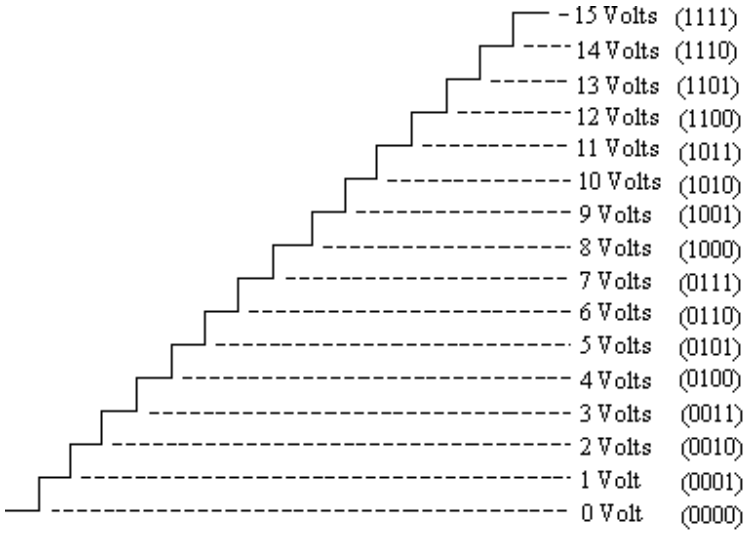

Fig. 13.1

Resistive divider network is used for converting digital inputs to analog outputs. The network for 6 bit binary system shown in figure 13.2 is known as the weighted network, as the resistors are weighted inversely with their current values. The input binary bits are b_5 b_4 b_3 b_2 b_1 b_0 where b_0 is the LSB and b_5 is MSB. These binary bits may be logic 0 or 1. Logic 0 may further be assumed as 0 volt and logic 1 as V_{REF}. So V_0, V_1, V_2, V_3, V_4 and V_5 are the input voltage levels which may be 0 volt or V_{REF} depending on the binary bits. The resistors R_0, R_1, R_2, R_3, R_4 and R_5 are connected to bits b_0, b_1, b_2 , b_3, b_4, b_5 respectively. It may be noted from this network that the resistor connected to the binary bit is half the value of resistor connected to the previous (lower) bit. Hence this network also called as the resistive divider network. Let R_L is the load resistance which is supposed to very high i.e. very much higher than the resistor R_0.

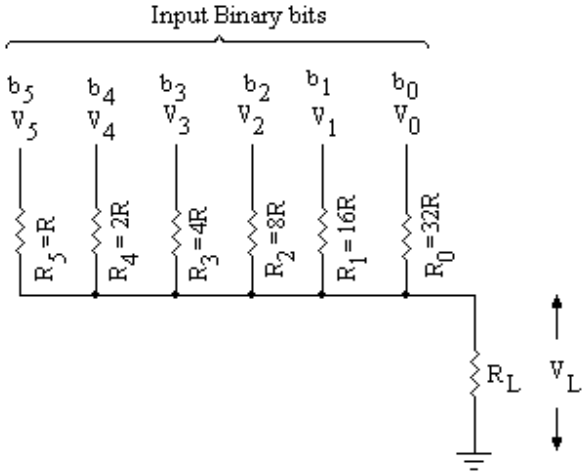

Fig. 13.2

Now the voltage V_L across the load resistance R_L can be obtained by using Millman's theorem. This theorem states that the voltage appearing at any node in a resistive network is equal to the sum of all the currents that would enter to the node divided by the sum of conductances connected to that node.

Thus

$$V_L = \frac{\frac{V_5}{R_5}+\frac{V_4}{R_4}+\frac{V_3}{R_3}+\frac{V_2}{R_2}+\frac{V_1}{R_1}+\frac{V_0}{R_0}}{\frac{1}{R_5}+\frac{1}{R_4}+\frac{1}{R_3}+\frac{1}{R_2}+\frac{1}{R_1}+\frac{1}{R_0}}$$

$$= \frac{\frac{V_5}{R}+\frac{V_4}{2R}+\frac{V_3}{4R}+\frac{V_2}{8R}+\frac{V_1}{16R}+\frac{V_0}{32R}}{\frac{1}{R}+\frac{1}{2R}+\frac{1}{4R}+\frac{1}{8R}+\frac{1}{16R}+\frac{1}{32R}}$$

$$= \frac{\frac{[32V_5+16V_4+8V_3+4V_2+2V_1+V_0]}{32}}{\frac{[32+16+8+4+2+1]}{32}}$$

$$= \frac{V_0+2V_1+4V_2+8V_3+16V_4+32V_5}{63}$$

$$= \frac{1}{(2^6-1)}(2^0V_0+2^1V_1+2^2V_2+2^3V_3+2^4V_4+2^5V_5) \quad \ldots(13.1)$$

In this equation (13.1), the load resistance R_L is not considered as it is assumed to be large enough offering low (almost zero) conductance. From this equation it is clear that if the input binary bits are all 1 (in a six bit system) and reference voltage V_{REF} = 6.4 volts (say), the V_L is given by:

$$V_L = \frac{1}{63} x 63 V_{REF} = 6.4 volts$$

In general, the equation (13.1) for output voltage of *n*-bit binary digits is given as:

$$V_L = \frac{1}{(2^n - 1)}(2^0 V_0 + 2^1 V_1 + 2^2 V_2 + 2^3 V_3 + 2^4 V_4 ..... + 2^{n-1} V_{n-1})$$

…(13.2)

The output of this network is as per our requirement, and is proportional to the input binary data.

Using the network discussed above, a D/A converter (called binary weighted D/A converter or Resistive divider D/A converter) can be designed as given below. The schematic diagram of 6-bit D/A converter is shown in figure 13.3. It consists of the following major parts:

(i) n switches, one for each bit applied to the input,

(ii) A binary weighted resistive network which changes each of the digital level into equivalent binary weighted voltage or current.

(iii) A reference voltage source V_{REF}.

(iv) A summing amplifier that adds the currents flowing in the resistors of the network to develop a signal that is proportional to the digital input.

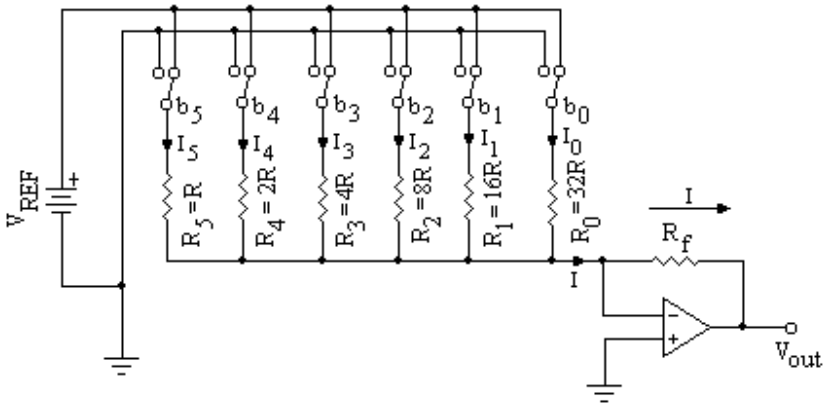

Fig. 13.3

In this circuit, one switch is connected to each binary bit. In fact these switches are such that when the binary bit is 0, the corresponding resistor of the network gets connected to the ground potential and when the binary bit is 1, the corresponding resistor of the network gets connected to the V_{REF} volt. The current flowing through any branch of the network will be the logical voltage (0volt or V_{REF} volts) divided by the corresponding resistor.

So the total current I will be given by (ref. fig. 11.3):

$$I = \frac{V_5}{R_5} + \frac{V_4}{R_4} + \frac{V_3}{R_3} + \frac{V_2}{R_2} + \frac{V_1}{R_1} + \frac{V_0}{R_0}$$

$$= \frac{V_5}{R} + \frac{V_4}{2R} + \frac{V_3}{4R} + \frac{V_2}{8R} + \frac{V_1}{16R} + \frac{V_0}{32R}$$

Since the voltages V_5 through V_0 are either 0 or V_{REF} volts depending upon the bit value, so it is customary to take common voltage V_{REF} and bits are kept in place of voltages. So V_5 is replaced by $V_{REF}.b_5$, V_4 by $V_{REF}.b_4$ and so on; the bits b_5, b4, b3 etc will be 0 or 1. The current I may, therefore, be represented as follows:

$$I = \frac{V_{REF}}{32R}\left[32b_5 + 16b_4 + 8b_3 + 4b_2 + 2b_1 + b_0\right]$$

$$= \frac{V_{REF}}{2^5.R}\left[2^0 b_0 + 2^1 b_1 + 2^2 b_2 + 2^3 b_3 + 2^4 b_4 + 2^5 b_5\right]$$

This is the equation of current I for 6 input bits. The general equation of current I for n input bits is given by:

$$I = \frac{V_{REF}}{2^{n-1}.R}\left[2^0 b_0 + 2^1 b_1 + 2^2 b_2 + 2^3 b_3 + 2^4 b_4 ..... + 2^{n-1} b_{n-1}\right] \quad \ldots(13.3)$$

The voltage at the output of operational amplifier will be given by:

$$V_{out} = -R_f.I$$

The resistor R_f is the feed back resistance in the operational amplifier. The output voltage of the operational amplifier is proportional to input binary data.

The switches connected in figure 13.3 can be replaced by the electronic switches (transistorized) as shown in figure 13.4. When the bit is at logic 1, the corresponding transistor conducts and the current flows through the collector resistor as required; and when the bit is at logic 0 the transistor goes into cutoff and no collector current flows.

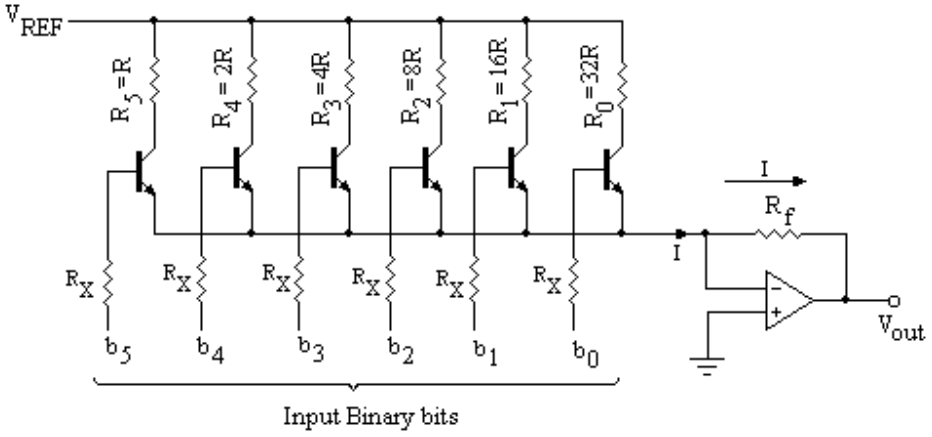

Fig. 13.4

This D/A converter is economical and simple method to design but suffers the following serious drawbacks:

1. The network in this D/A converter is constructed using the precession resistors and resistors have different values. So it is difficult in practice to choose the resistors with accuracy and stability.
2. When the number of bits in the network is large, then the current from the source will be large enough. The current in the MSB branch (resistor) will be much larger than LSB branch. In a 10 bit D/A converter, the current in MSB branch will be 512 times larger than the MSB branch.

13.1.2 Binary Ladder D/A Converter

A more commonly used D/A converter is a binary ladder D/A converter, which removes the drawbacks discussed in resistive divider D/A converter. This type of D/A converter contains an R-2R ladder network. The R-2R resistive ladder network will now be discussed, which gives the output a weighted sum of digital inputs. Such a ladder

network for 4-bit input is shown in figure 13.5. This network is constructed having only two resistor values i.e. R and 2R. In this network b_0, b_1, b_2 and b_3 are the input binary bits and b_0 is the LSB and b_3 is MSB. Any of these bits will be at the ground potential when the corresponding bit is at logic 0 or at the reference potential (V_{REF}) when the input bit is at logic 1.

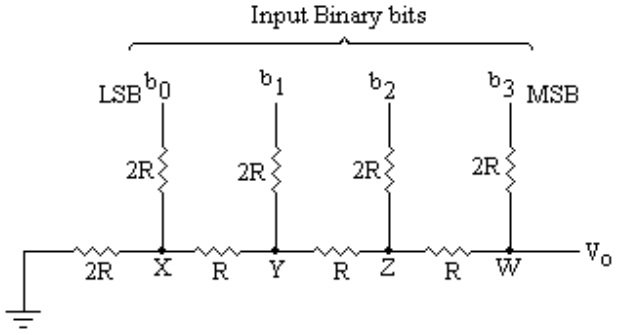

Fig. 13.5

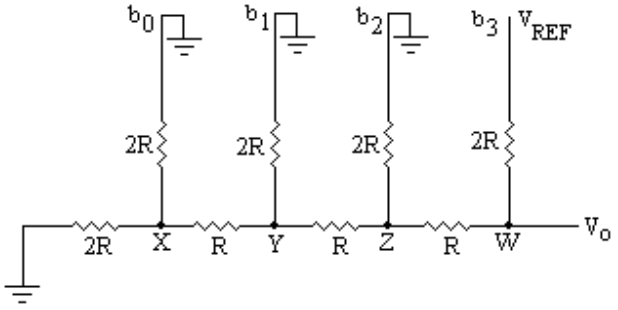
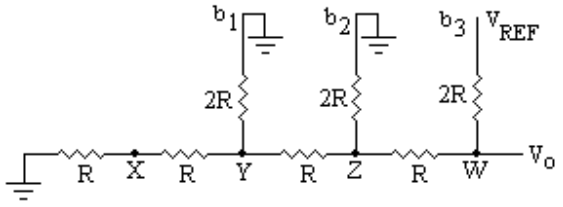
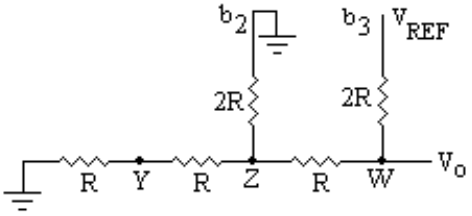
To examine the behaviour of this network, it is assumed that the bit b_3 is at logic 1 (or V_{REF} potential) as shown in figure 13.6(a). The output voltage corresponding to MSB may be calculated as follows. The equivalent resistance at the point X is the parallel combination of two resistances each having the value of 2R. So the equivalent resistance looking at point X and ground is R as shown in figure 13.6(b). At the point Y again there is a parallel combination of two 2R resistances; the equivalent resistance looking at the point Y and ground is R as shown in figure 13.6(c). Similarly, one can find the equivalent resistance looking at the point Z and ground is R as shown in figure 13.6(d).



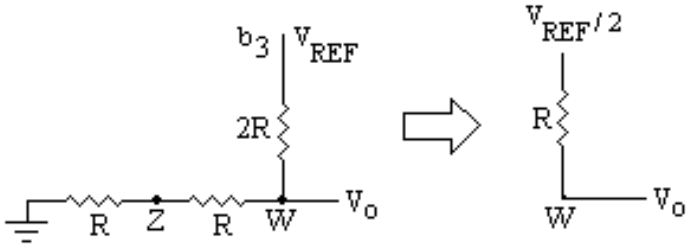
(a)



(b)



(c)



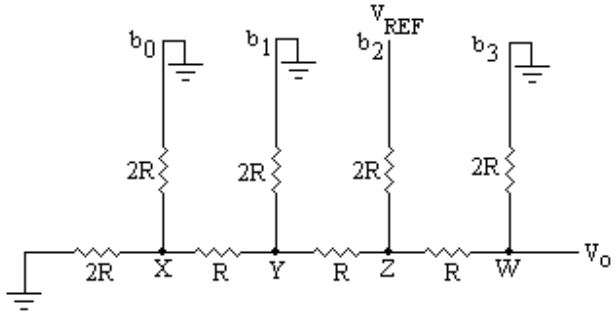
(d)

Fig. 13.6

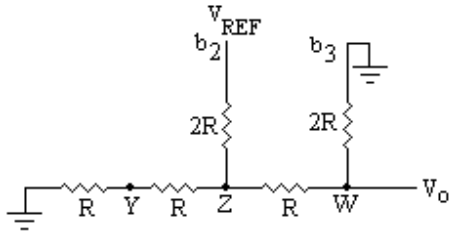
From figure 13.6(d) it is clear that the resistance looking at the point W and ground is 2R, and the resistance looking towards the bit b_3 is also 2R. Thus the output voltage at the point W due to bit b_3 (MSB) assumed at V_{REF} potential is given by:

$$V_0 = \frac{V_{REF} x 2R}{(2R + 2R)} = \frac{V_{REF}}{2}$$

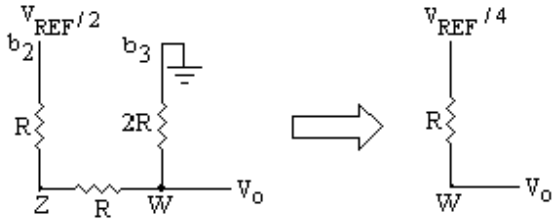
The output voltage V_0 due to the binary input 1000 (only MSB is high) is half of the reference voltage having Thevenis's resistance R in series with it. Similarly one can calculate the output voltage due to the binary input 0100 (i.e. second MSB); the network for this case is shown in figure 13.7(a). The resistance looking at the point Y and ground is R as shown in figure 13.7(b). The resistance between the point Z and ground is 2R. The voltage at point Z and ground is (V_{REF}/ 2) have a Thevenin's resistance R, as shown in figure 13.7(c).



(a)



(b)



(c)

Fig. 13.7

From this figure the output voltage V_0 at the point W is given by:

$$V_0 = \frac{(V_{REF}/2)x2R}{(2R+2R)} = \frac{V_{REF}}{4}$$

So the output voltage due to second MSB (or for binary input 0100) is $\frac{V_{REF}}{4}$ with Thevenin's resistance R in series with it.

It can further be shown that the output due to third MSB (for binary input 0010) is $\frac{V_{REF}}{8}$. And for LSB (0001 binary input) the output is $\frac{V_{REF}}{16}$. Each voltage source will have Thevenin's resistance R in series with the source. The total output voltage in analog form, due to all the inputs as 1 (for 1111) can easily be found by adding the outputs obtained for each bit as given below:

$$V_0 = \frac{V_{REF}}{2} + \frac{V_{REF}}{4} + \frac{V_{REF}}{8} + \frac{V_{REF}}{16}$$

It may be noted that $\frac{V_{REF}}{2}$ is the voltage due to MSB, $\frac{V_{REF}}{4}$ due to second MSB, $\frac{V_{REF}}{8}$ for third MSB and $\frac{V_{REF}}{16}$ for LSB. So to distinguish these voltages it is useful to write the bit positions along with V_{REF} as given below. So if the bit is 0 the voltage corresponding to that bit will be zero otherwise the voltage as discussed above.

$$V_0 = \frac{V_{REF}xb_3}{2} + \frac{V_{REF}xb_2}{4} + \frac{V_{REF}xb_1}{8} + \frac{V_{REF}xb_0}{16}$$

$$= \frac{V_{REF}}{16}\left[8xb_3 + 4xb_2 + 2xb_1 + 1xb_0\right]$$

$$= \frac{V_{REF}}{2^4}\left[2^0 xb_0 + 2^1 xb_1 + 2^2 xb_2 + 2^3 xb_3\right] \quad \ldots(13.4)$$

The equation (13.4) is the equation for voltage at the output of 4 bit binary ladder network. A general equation for the output of *n*-bit binary data can be given as follows:

$$V_0 = \frac{V_{REF}}{2^n}\left[2^0 xb_0 + 2^1 xb_1 + 2^2 xb_2 + 2^3 xb_3 + ... + 2^{n-1} xb_{n-1}\right] \quad \ldots(13.5)$$

The output of this network is proportional to the input binary data. So using this R-2R ladder network, a D/A converter (called binary ladder D/A converter) can be designed as given below. The schematic diagram of 4-bit D/A converter is shown in figure 13.8. It consists of the following major parts.

(i) n switches, one for each bit applied to the input,
(ii) A binary ladder network which changes each of the digital level into equivalent binary weighted voltage or current.
(iii) A reference voltage source V_{REF}.
(iv) A summing amplifier that adds the currents flowing in the resistors of the network to develop a signal that is proportional to the digital input.

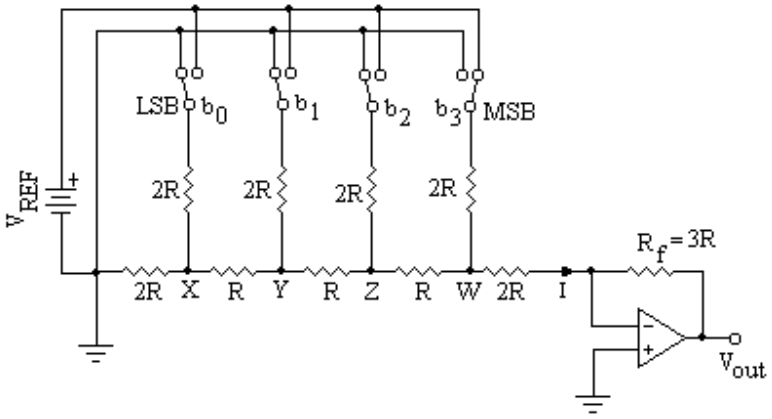


Fig. 13.8

The output voltage V_{out} of this D/A converter due to MSB (1000 binary input) will be calculated as given below:

The voltage at the point W due to MSB is V_{REF} / 2 having a Thevenin's resistance R in series with it as discussed above and is shown in figure 13.9

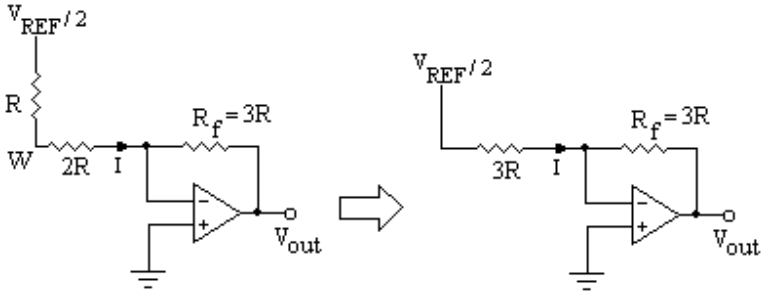

Fig. 13.9

From this figure, the current I is given by:

$$I = \frac{V_{REF}}{2}(\frac{1}{3R})$$

and the output voltage V_{out} is given by:

$$Vout = -I.R_f$$

$$= -\frac{V_{REF}}{2}(\frac{1}{3R}).3R = -\frac{V_{REF}}{2}$$

The output voltage is the same as calculated in equation 13.5, with the difference that it has a negative value because the operational amplifier is used in inverting configuration.

Note that the resistors in the ladder network are either R or 2R. It is the ratio of resistances matters rather than the absolute value of resistances. Further the resistors do not cover a wide range of magnitude; it is, therefore, practically possible to get the precision in the ratio of their magnitudes. The temperature coefficients of these resistances can easily match. Because of these advantages, the ladder network is widely used in D/A converters.

13.2 PERFORMANCE CRITERIA FOR D/A CONVERTER

The D/A converters are available in the form of ICs with different specifications for their performances. So before discussing D/A converter ICs it will be better to discuss first the characteristics of the converters specified by the manufacturers. These specifications include:

1. Resolution
2. Accuracy
3. Monotonicity
4. Settling time

1. **Resolution:** As discussed above, the analog output of D/A converter is proportional to the digital input (binary data), so a perfect staircase is obtained if there is an LSB increment. The resolution is, therefore, a measure of quality of D/A converter, which is defined as the ratio of the LSB increment to the maximum output. For an *n*-bit D/A converter the resolution is given by:

The change in output due to LSB increment for n-bit digital input (Step size)

= Full scale output / No. of steps

$$= \frac{\text{Full scale output}}{2^n - 1}$$

where $(2^n - 1)$ is the number of steps for n-bit D/A converter.

$$\text{Percentage Resolution} = \frac{\text{Full scale output} / (2^n - 1)}{\text{Full scale output}} \times 100\%$$

$$= \frac{1}{2^n - 1} \times 100\%$$

The step size for a 10 bit D/A converter, having full scale output voltage as 10 volts, is given by $= \frac{10}{2^{10} - 1} = \frac{10}{1023} = 9.8mV$

And % Resolution = 0.0978%

2. Accuracy: Accuracy of a D/A converter is the closeness of the output analog voltage to the expected theoretical output. In a linear variation of analog output with digital input, the relative accuracy is the maximum deviation of the D/A output compared with the linear behaviour. It is expressed as a percent of a full-scale or maximum output voltage. For example, if a converter has a full scale output of 10 V and the accuracy is $\pm 0.1\%$, then the maximum error for any output voltage is (10V)(0.001) = 10 mV. Ideally, the accuracy should be at most ± ½ of an LSB.

For an 8 bit D/A converter, one LSB is $\frac{1}{256} = 0.0039 = 0.39\%$ of full scale. The accuracy should be approximately $\pm 0.2\%$.

3. Monotonicity: A D/A converter is said to be monotonic if it gives an analog output voltage which increases regularly and linearly with increase in input digital signal. Such a quality of the converter is called as monotonicity. In order to demonstrate monotonicity of a D/A converter, a counter output is given as digital input to a D/A converter and the analog output is displayed on the CRO. Monotonicity then requires that the output waveform should be a perfect staircase waveform with steps equally spaced and of same magnitude. If the steps are missing or have varying magnitude, the D/A converter is defective.

4. Settling Time: After the application of digital input to a D/A converter, it takes about few nanoseconds to microseconds to produce the correct output. So the settling time is defined as the time the converter takes to give an output to settle within ± ½ LSB of its final value. For example, if a D/A converter has a resolution of 10mV, the settling time is the measure of the time the converter takes to settle with in ± 5mV of its final value. Figure 13.10 illustrates the settling time in a D/A converter. The settling time is important because it places a limit on how fast one can change the digital input. The settling time depends on the stray capacitance, saturation delay time, and other factors.

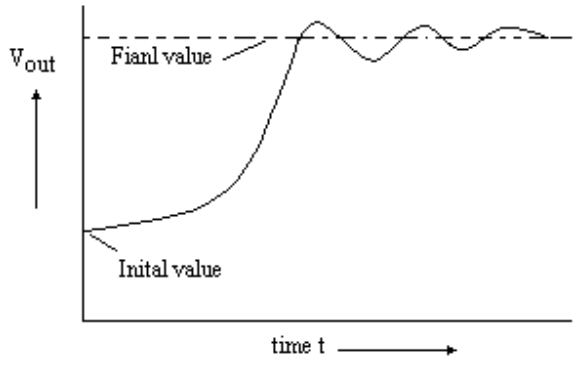

Fig. 13.10

13.3 D/A CONVERTER IC 0808

There are many commercially available D/A converter ICs. The IC 0808 is the most popular, inexpensive and widely used 8 bit D/A converter. It contains a reference current source, an R-2R binary ladder network and 8 transistor switches to steer the binary currents to the network. Figure 13.11 shows the pin configuration of this D/A converter IC 0808.

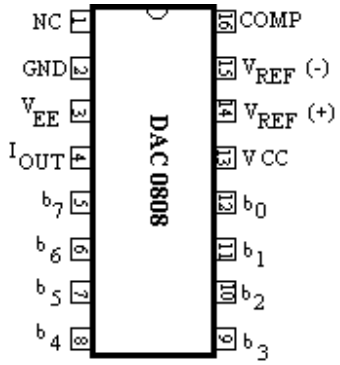

Fig. 13.11

In this IC, pins 5 through 12 are the 8 bit input data, so should be connected to input data bits. Pin 15 is to be connected to ground through a resistance. Pin 13 is to be connected to +5 volt supply. Pin 3 (V_{EE}) is to be connected to – 15 volts. Pin 4 is the output current of the ladder network should be connected to the operational amplifier. Pin 2 is the ground pin. The pin 16 is the frequency compensation pin, a capacitor between pin 16 and 3 is to be connected for this purpose.

A circuit diagram to get the analog output voltage corresponding to 8 bit digital input is shown in figure 13.12. A +5 V supply sets up a reference current of 2mA for the ladder. The output current I_{out} drives the operational amplifier to give final output between 0 and 2 volts (approximately) for the 8 bit digital input.

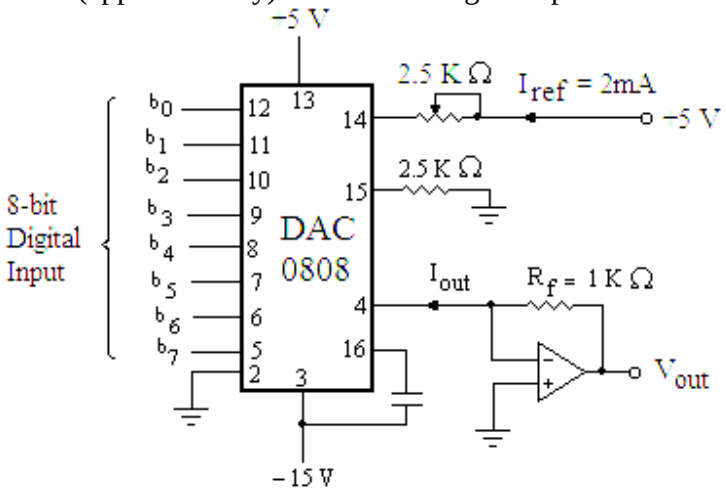

Fig. 13.12

There are many other commercially available D/A converter as given below:

DAC 0800 – A monolithic 8-bit high speed current output DAC.

DAC 0806 and DAC 0807 – 8 bit monolithic D/A converters.

DAC 1000 and DAC 1008 – 10 bit microprocessor compatible advanced CMOS D/A converters.

DAC 1202 and DAC 1203 – Three-digit (BCD) D/A converter.

13.4 INTERFACING OF D/A CONVERTER

For the interfacing of 0808 D/A converter with the microprocessor 8085A, the circuit shown in figure 13.12 may be connected to the system through the 8255 PPI (Programmable Peripheral Interface as shown in figure 13.13.

Fig. 13.13

In this circuit feedback resistor R_f is considered as 5 KΩ and the reference voltage is taken as V_{REF} = 10 V, so that we get the output current I_{Out} as:

$$I_{Out} = \frac{I_{REF}}{2^n}\left[2^0 xb_0 + 2^1 xb_1 + 2^2 xb_2 + 2^3 xb_3 + ... + 2^{n-1} xb_{n-1}\right]$$

Here the value of n = 8 as it is 8 bit D/A converter.

So $$I_{Out} = \frac{I_{REF}}{256}\left[2^0 xb_0 + 2^1 xb_1 + 2^2 xb_2 + 2^3 xb_3 + ... + 2^{n-1} xb_{n-1}\right]$$

and $$I_{REF} = \frac{V_{REF}}{R_{REF}} = \frac{10V}{5K\Omega} = 2mA$$

and $$V_{OUT} = \frac{2mA}{256}\left[2^0 xb_0 + 2^1 xb_1 + 2^2 xb_2 + 2^3 xb_3 + ... + 2^{n-1} xb_{n-1}\right]xR_f$$

$$= \frac{10}{256}\left[2^0 xb_0 + 2^1 xb_1 + 2^2 xb_2 + 2^3 xb_3 + ... + 2^{n-1} xb_{n-1}\right]$$

If all the input bits (b_0 – b_7) are 1 (FF H), then the output voltage (known as full scale output voltage) is given by:

$$V_{OUT} = \frac{255}{256} x10 \approx 10V$$

The output voltage corresponding to the input 1000 0000 (80 H) is given by:

$$V_{OUT} = \frac{128}{256} x10 = 5V$$

So we have the linear output corresponding to the binary inputs i.e.

Digital Input	Output Voltage
00 H	0 V
80 H	5 V
FF H	10 V

These input output levels may be verified, if the following three programs are executed and the voltages at the outputs in the three cases are measured.

Program 1:

```
MVI A, 80 H     ; 8255 is initialized with all the ports as
                  output port.
OUT  03 H       ; Control word is written in control word
                  register.
MVI A, 00 H     ; Get A = 00 H, so that 00 H is applied to the
                  input of D/A converter.
OUT 00 H        ; 00 H is available at the Port A of 8255 so
                  that it is applied to the input of D/A
                  converter.
HLT             ; Stop processing.
```

After execution of this program, if the voltage at the output of the circuit of D/A converter is measured we get 0 V. It verifies that 00 H is applied at the input of the converter, we get 0 V.

Program 2:

```
MVI A, 80 H     ; 8255 is initialized with all the ports as
                  output port.
```

```
OUT  03 H        ; Control word is written in control word
                   register.
MVI A, 80 H      ; Get A = 80 H, so that 80 H is applied to the
                   input of D/A converter.
OUT 00 H         ; 80 H is available at the Port A of 8255 so
                   that it is applied to the input of D/A
                   converter.
HLT              ; Stop processing.
```

After execution of this program, if the voltage at the output of the circuit of D/A converter is measured we get 5 V. It verifies that 80 H is applied at the input of the converter, we get 5 V.

Program 3:

```
MVI A, 80 H      ; 8255 is initialized with all the ports as
                   output port.
OUT  03 H        ; Control word is written in control word
                   register.
MVI A, FF H      ; Get A = FF H, so that FF H is applied to
                   the input of D/A converter.
OUT 00 H         ; FF H is available at the Port A of 8255 so
                   that it is applied to the input of D/A
                   converter.
HLT              ; Stop processing.
```

After execution of this program, if the voltage at the output of the circuit of D/A converter is measured we get 10 V. It verifies that FF H is applied at the input of the converter, we get 10 V.

Example 13.1. *The input bits of the D/A converter is connected to the output pins of Port A of 8255, which is already connected with the microprocessor (ref. fig.13.13). Write a program to generate stair case voltage with ten steps. It should have the constant pulse duration.*

Solution. There should be 10 steps for the stair case voltage to be generated with the D/A converter. So the height of the stair case should be approximately 1 volt. Since FF H gives 10 volts, so 19 H should be decreased each time in 10 go.

When 19 H is subtracted from FF H in the first go we get E6 H. The output voltage corresponding to E6 H is given by:

$$V_{Out} = \frac{230}{256} x10 = 8.984 \text{ volts}$$

Therefore, the subtraction of 19 H from FF H gives a decrement of 1 volt at the output. The program for the generation of stair voltage is given as:

PROGRAM

Label	**Mnemonics**	**Operand**	**Comments**
	MVI A,	80 H	; Initialize 8255-I to work all the ports as output ports.
	OUT	03 H	; Write the control word (80 H) in the control word register of 8255-I.
START	MVI A,	FF H	; Load FF H to accumulator.

```
                OUT         00 H        ; Send FF H (10 V) to PA0.
                CALL        DELAY       ; Jump to delay subroutine to
                                          introduce a delay of constant pulse
                                          width.
                MVI B,      00 H        ; Use B-register as counter for 10
                                          steps.
REPEAT          SBI         19 H        ; Subtract 19 H to calculate next
                                          weight for the output of D/A
                                          converter.
                OUT         00 H        ; Send the data to the output.
                INR B                   ; Increment B-register.
                CPI         0A H        ; If 10 steps complete then
                JZ          END         ; Jump to repeat the process.
                PUSH PSW                ; Save PSW
                PUSH B                  ; Save B-C register pair.
                CALL        DELAY       ; Jump to delay subroutine to
                                          introduce a delay of constant pulse
                                          width.
                POP B                   ; Restore the contents of B-C pair.
                POP PSW                 ; Restore the PSW.
                JUMP        REPEAT      ; Jump to repeat to output for the
                                          next weight.
END             MVI A,      00 H        ; Store 00 H to the accumulator.
                OUT         00 H        ; Outputs for 00 H.
                CALL        DELAY       ; Jump to delay subroutine to
                                          introduce a delay of constant pulse
                                          width.
                JMP         START       ; Repeat for next cycle.
```

SUBROUTINE PROGRAM:

```
    Label     Mnemonics     Operand     Comments
    DELAY     LXI D,        0020 H      ; Loads DE register pair with a 16-
                                          bit number.
    LOOP1     DCX D                     ; Decrements DE register pair by 1.
              MOV A,        E           ; Moves the contents of E register to
                                          accumulator.
              ORA D                     ; ORing of the contents of D and E
                                          registers are performed to set the
                                          zero flag.
              JNZ           LOOP1       ; If result is not zero than jump to
                                          LOOP1.
              RET                       ; Go back to main program.
```

In the subroutine program, DE register pair may be loaded with any other 16-bit number to change the pulse width. The exact time of the pulse width may be calculated as discussed in the delay programs. After the execution of this program, the output may be seen on the CRO. The output will be stair case wave.

Example 13.2. *Write a program to generate square wave of 1 KHz frequency with a peak voltage of 2.5 volts. Use D/A converter (ref. fig. 13.13) for this purpose. The square wave should be available at the output of the converter.*

Solution. It is required to generate square wave of 1 KHz frequency, the time period of such wave should be 1msec. During 1 msec the output should be high for 0.5 msec and low for the same time. Time delay can be introduced by using the following subroutine program:

SUBROUTINE PROGRAM:

Label	Mnemonics	Operand	Comments
DELAY	LXI D,	0040 H	;Loads DE register pair with a 16-bit number.
LOOP	DCX D		;Decrements DE register pair by one.
	MOV A,	E	;Moves the contents of E register to accumulator.
	ORA D		;ORing of the contents of D and E registers are performed to set the zero flag.
	JNZ	LOOP	;If result $\neq 0$ jump to loop
	RET		;Go back to main program.

Total T-states used for the above sub routine program are given as:

Mnemonics	T-states
LXI	10
DCX	5
MOV	5
ORA	4
JNZ LOOP	10/7
RET	10

24 T-states are used for the inner loop and 10+7+10 = 27 T-states are used for outer loop.

In this program the execution of loop is for 64 times (as 0040 H = 64_{10}). The condition for the check of zero flag can not be applied just after DCX instruction, since no flag gets affected with this instruction. So to check the zero flag ORA instruction affect the zero flag. The zero flag will be set if the contents of both D and E registers are zero.

The time delay introduced by the inner loop is:

$$T_{LOOP} = 64 \times 24 \times \text{Time of one T-state.}$$

If the system clock frequency is 3 MHz, then

$$T_{LOOP} = 64 \times 24 \times \frac{1}{3}\mu\text{sec}$$

$$= 512\ \mu\text{sec}$$

$$= 0.5\ \text{msec.}$$

Delay introduced for outside loop is:

$$T_{out} = 27x1x\frac{1}{3}\mu sec$$
$$= 9\ \mu sec$$

So the total time delay introduced by the above subroutine program is given by:

$$T_{Delay} = 0.5\ msec + 9\ \mu sec$$
$$\approx 0.5\ msec$$

Further, it is required that the voltage level of the output should be 2.5 volts, for which the digital input should be 40 H as 80 H gives 5 volts. So the main program is given as:

MAIN PROGRAM

Label	**Mnemonics**	**Operand**	**Comments**
	MVI A,	80 H	; Initialize 8255-I to work all the ports as output ports.
	OUT	03 H	; Write the control word (80 H) in the control word register of 8255-I.
START	MVI A,	00 H	; Load 00 H to accumulator.
	OUT	00 H	; Send 00 H (00 V) to PA_0.
	PUSH PSW		; Save PSW
	CALL	DELAY	; Jump to delay subroutine to introduce a delay of 0.5msec.
	POP PSW		; Restore the PSW.
	MVI A,	40 H	; Store 40 H to the accumulator.
	OUT	00 H	; Outputs for 40 H.
	PUSH PSW		; Save PSW
	CALL	DELAY	; Jump to delay subroutine to introduce a delay of 0.5msec.
	POP PSW		; Restore the PSW.
	JMP	START	; Repeat the process for next cycle.

During the execution of this program the wave shape at output of the D/A converter can be checked. It will be a square wave of 1 KHz frequency.

Example 13.3. *Write a program to generate a triangular wave form using 8255 and DAC 0808 (ref. fig. 13.13).*

Solution. The program for the same is given below:

MAIN PROGRAM

Label	**Mnemonics**	**Operand**	**Comments**
	MVI A,	80 H	; Initialize 8255-I to work all the ports as output ports.
	OUT	03 H	; Write the control word (80 H) in the control word register of 8255-I.
LOOP	MVI A,	FF H	; Load FF H to accumulator.
	OUT	00 H	; Send FF H (10 V) to PA_0.
	INR A		; Increment accumulator.
	OUT	00 H	; Output corresponding to this weight is available (i.e. increasing

```
                                        voltage is available at the output of
                                        the converter).
          CPI       FF H          ; Compare if output has become 10
                                      Volts.
          JZ        LOOP 1        ; If yes go to LOOP 1.
          JMP       LOOP          ; If no go to LOOP.
LOOP 1    DCR  A                  ; Decrement accumulator.
          OUT       00 H          ; Outputs for decrement data.
          JZ        LOOP          ; If accumulator content becomes 0,
                                      go to LOOP.
          JMP       LOOP          ; Else to LOOP.
```

During the execution of this program the wave shape at output of the D/A converter can be checked. It will be triangular wave.

13.5 MICROPROCESSOR COMPATIBLE D/A CONVERTER

Now a days microprocessor compatible D/A converters are also available, which are designed for the purpose of directly interfacing with the microprocessor without the use of external latch. Among such converters, AD558 is very simple, inexpensive and commonly used D/A converter to be connected directly to the microprocessor.

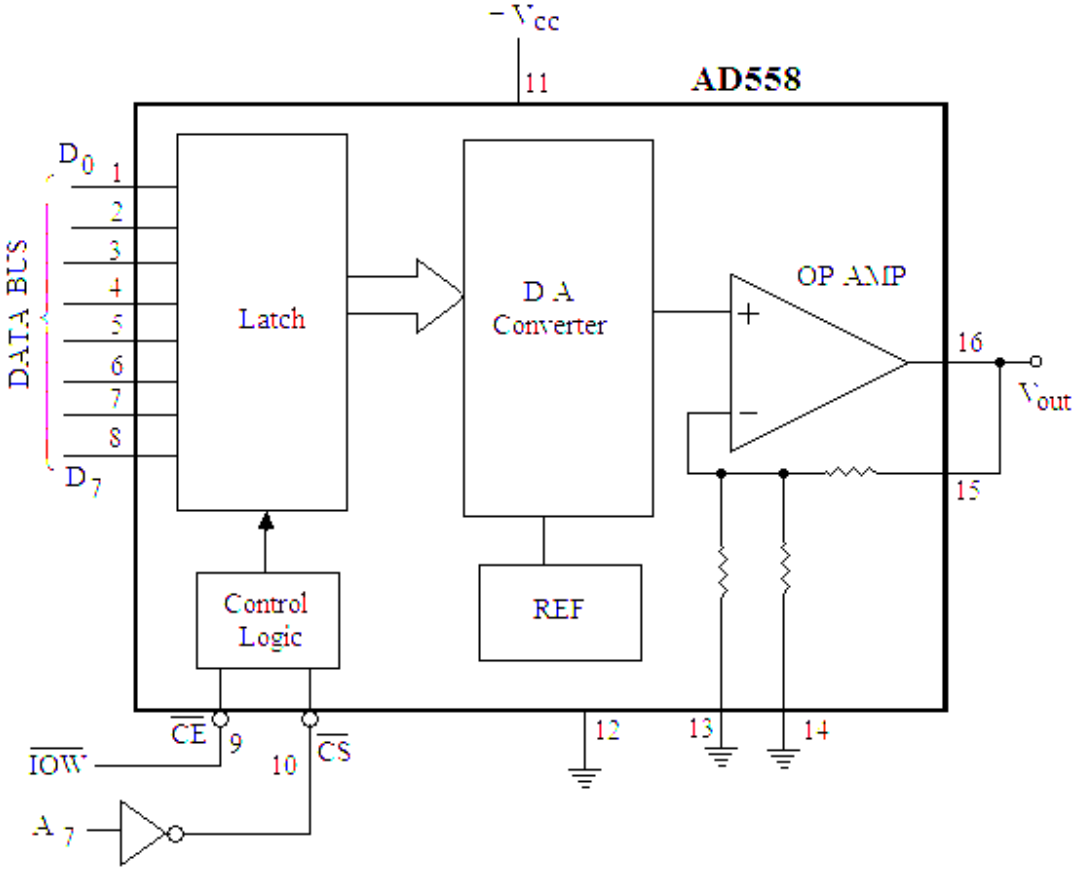

Fig. 13.14

Figure 13.14 shows the block diagram of this D/A converter, which includes internally a latch and output op amp. It can be operated with + 4.5 V to 16.5 V d.c. power

supply. Two pins $\overline{CS}$ (chip select) and $\overline{CE}$ (chip enable) are provided with the chip to interface with the microprocessor 8080 or 8085. For the interfacing with 8085 $\overline{CE}$ may be connected to $\overline{IOW}$ of the processor and $\overline{CS}$ may be connected to the A_7 bit of the address line. The other pins of the address lines may be assumed as 0, so that 80 H will be the port address of this converter. When both the signals $\overline{CS}$ and $\overline{CE}$ are at logic 0, the latch is transparent means the input is transferred to the D/A block of this converter. When either of $\overline{CS}$ or $\overline{CE}$ goes to logic 1, the input is latched in the register and held until both control signal go to logic 0.

The programs given in the above examples (solved) can be executed with this converter by using the proper port address.

13.6 ANALOG TO DIGITAL CONVERTER

Generally the information to be processed by the digital systems is in the analog form. So before applying such signals to the digital systems it is necessary to convert the signal into its equivalent digital form. The method with the help of which the analog signal is converted to digital form is known as analog to digital (A/D) converter. The A/D converter is more complex and difficult than the D/A converter. Followings are the different methods for A/D converter, which will be discussed in the next sections.

(i) Simultaneous A/D converter
(ii) Successive approximation D/A converter
(iii) Counter or Digital Ramp type A/ D converter
(iv) Single slope D/A converter
(v) Dual slope D/A converter

13.7 SIMULTANEOUS A/D CONVERTER

This is the fastest and simplest method of converting an analog signal to digital signal. It utilizes the parallel differential comparators; the input analog voltage is compared by these comparators with known voltages called as reference voltages. The comparators gives the low output (logic 0) when the input is less than the reference voltage and gives the high output (logic 1) when the input analog voltage exceeds the reference voltage. This method of conversion is also called as Flash or parallel type A/D converter.

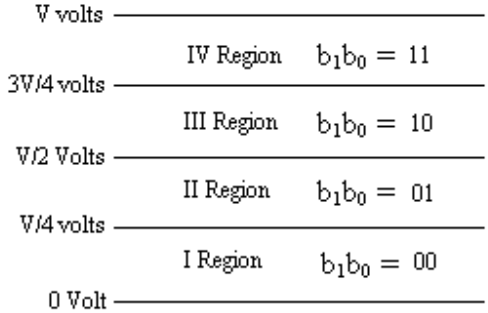

Fig. 13.15

For the conversion of analog voltage ranging between 0 to V volts into two bit digital output, three comparators (in general $2^n - 1$ comparators where n in the number of

bits) are required. The input analog voltage is converted to the 4 (in general 2^n) equal regions as shown in figure 13.15. If the analog voltage is lying in the first region, then the binary bits (b_1, b_0) are 00, similarly to second, third and forth regions the binary bits are 01, 10 and 11 respectively. The reference voltages to the three comparators C_0, C_1, C_2 should be V/4, V/2, 3V/4 respectively as shown in figure 13.16. The output of the three comparators should be connected to the logic gates to produce the desired binary output. The read gates and output registers are used to read the digital output.

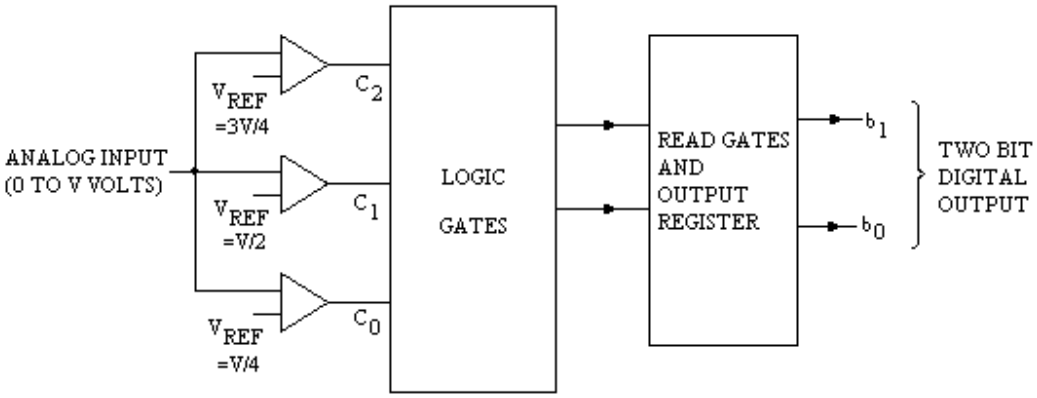

Fig. 13.16

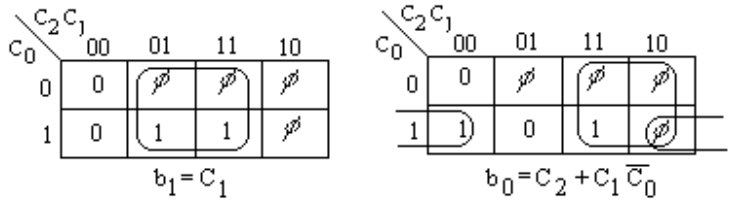
Referring to figures 13.15 and 13.16, if the input analog voltage exceeds the reference voltage to any comparator, the comparator gives high output (logic 1); if on the other hand if the input analog voltage is less than the reference voltage of the comparator, it gives low output (logic 0). In this way if all the comparators give low output, the analog input voltage must be between 0 and V/4 volts (I region) and digital binary output should be 00. If the C_0 is high and C_1 and C_2 are low, the input must be between V/4 and V/2 volts (II region) and digital binary output should be 01. If C_0 and C_1 are high and C_2 is low, the input must be between V/2 and 3V/4 volts (III region) and digital binary output should be 10. Finally if all the comparators give high outputs, the input must lies 3V/4 and V volts (IV region) and digital binary output should be 11. Table 13.2 summarizes outputs of the comparators.

Table 13.2

	Comparator output			Binary output	
Input voltage	C_2	C_1	C_0	b_1	b_0
0 to V/4	0	0	0	0	0
V/4 to V/2	0	0	1	0	1
V/2 to 3V/4	0	1	1	1	0
3V/4 to V	1	1	1	1	1

By drawing the K –maps (figure 13.17), the expressions for b_0 and b_1 are obtained as:

$$b_1 = C_1 \qquad \text{and} \qquad b_0 = C_1 \cdot \overline{C}_0$$



(a) **(b)**

Fig. 13.17

These expressions may be realized using the gates as shown in figure 13.18. The output may be reset by applying high signal to the reset line and to read the data a high signal is applied to the read line.

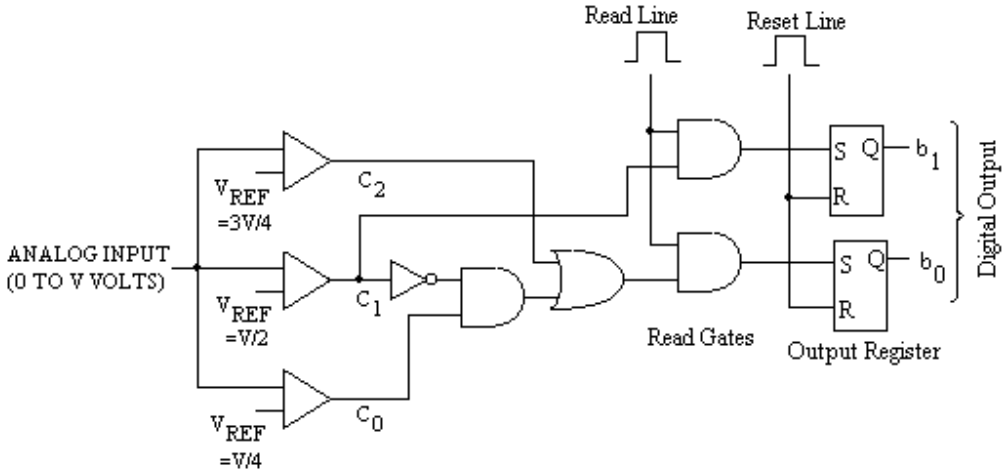


Fig. 13.18

For the conversion of analog input voltage (0 to V volts) into three bit binary output we proceed in the similar method as for the two bits output. For the three bits outputs the input voltages are divided into 8 (as $2^3 = 8$) equal regions and 7 (as $2^3-1 = 7$) comparators are to be used. So the logic circuit to be designed should have seven inputs (output of the seven comparators) and three outputs. The output of comparators and the corresponding binary output are shown in table 13.3.

Table 13.3

Input voltage	Comparator output							Binary output		
	C_6	C_5	C_4	C_3	C_2	C_1	C_0	b_2	b_1	b_0
0 to V/8	0	0	0	0	0	0	0	0	0	0
V/8 to V/4	0	0	0	0	0	0	1	0	0	1
V/4 to 3V/8	0	0	0	0	0	1	1	0	1	0
3V/8 to V/2	0	0	0	0	1	1	1	0	1	1
V/2 to 5V/8	0	0	0	1	1	1	1	1	0	0
5V/8 to 3V/4	0	0	1	1	1	1	1	1	0	1
3V/4 to 7V/8	0	1	1	1	1	1	1	1	1	0
7V/8 to V	1	1	1	1	1	1	1	1	1	1

The expressions of the output bits can easily be obtained by examining the table 13.3.

The bit b_2 gives the high output whenever the output of the comparator C_3 is high. So $b_2 = C_3$.

The bit b_1 is high whenever the output of comparator C_1 is high and output of C_3 is low, or whenever the output of comparator C_5 is high. So $b_1 = C_1 \cdot \overline{C}_3 + C_5$.

Similarly, the expression for bit b_0 can be obtained as:

$$b_0 = C_0 \cdot \overline{C}_1 + C_2 \cdot \overline{C}_3 + C_4 \cdot \overline{C}_5 + C_6$$

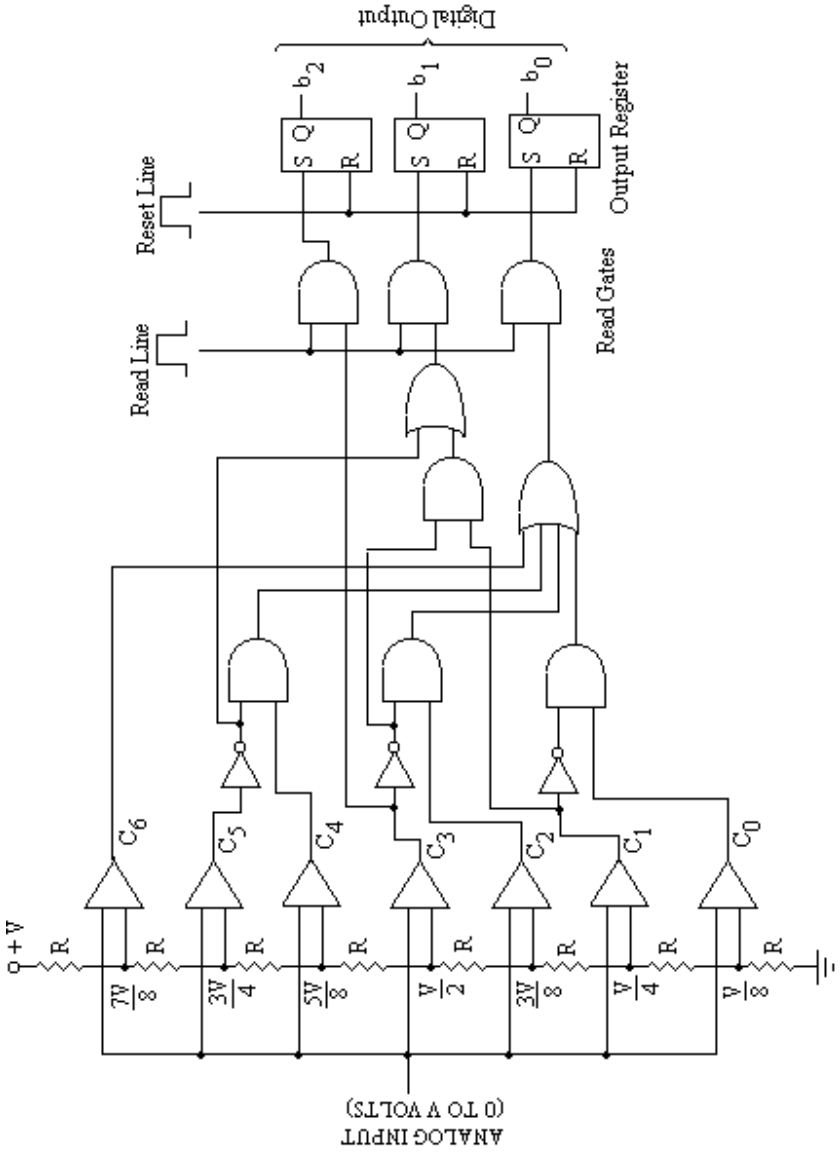

Fig. 13.19

These expressions may be realized using the gates as shown in figure 13.19. The output may be reset by applying high signal to the reset line and to read the data a high signal is applied to the read line.

The design of a simultaneous A/D converter is quite straight forward and relatively easy to understand. However, the design becomes complicated as the number

of bits is increased, since the number of comparators to be used increases drastically. This method has highest speed of conversion.

13.8 SUCCESSIVE APPROXIMATION A/D CONVERTER

Simultaneous A/D converter has the very fast conversion time but becomes unwieldy when the required digital bits are more. The successive approximation method is most useful and commonly used method. The block diagram four bit successive approximation A/D converter is shown in figure 13.20. It consists of a D/A converter, successive approximation register (SAR) and a comparator. The basic principle of this A/D converter is as follows:

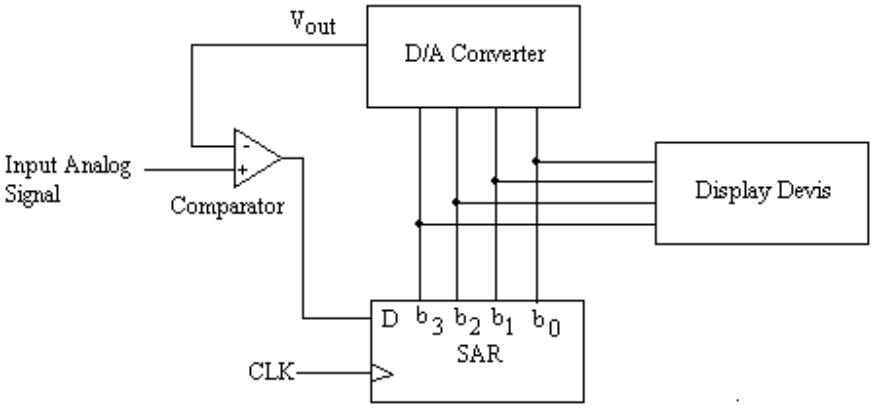

Fig. 13.20

In this type of converter, the bits of D/A converter are enabled one by one, starting with the most significant bit (MSB). The analog output of the D/A converter corresponding to the enabled bit is compared with the input analog voltage. The comparator gives the output low if the input analog voltage is less than the output of the D/A converter and it gives the high out if the input analog voltage is more than the output of the D/A converter. The low output of the comparator resets the corresponding bit of SAR, on the other hand if the comparator's output is high then that bit is retained in SAR. In this way the output of D/A converter are compared with the input voltage for all the bits starting with the most significant bit.

Thus the successive approximation method is the process of approximating the analog voltage bit by bit starting with MSB. This process is shown in figure 13.21.

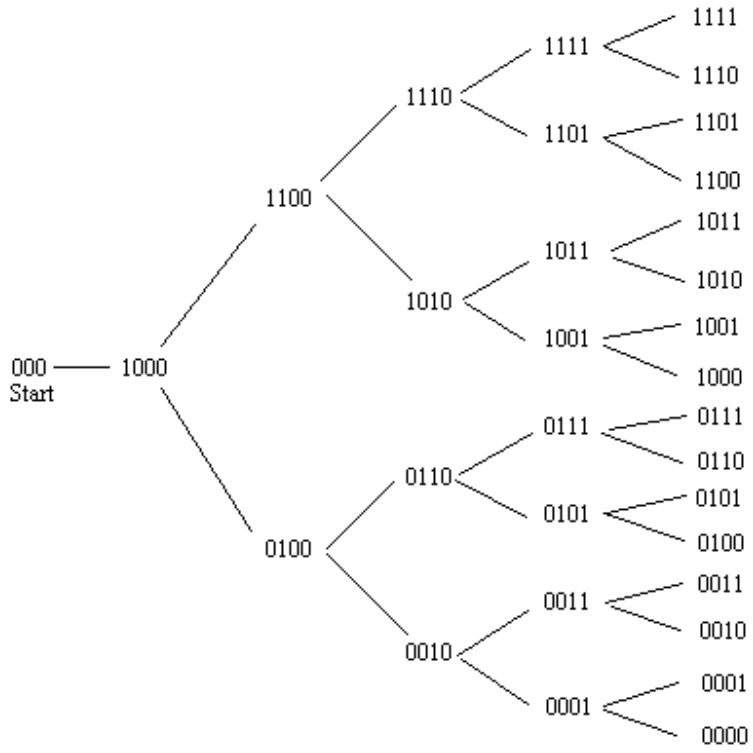

Fig. 13.21

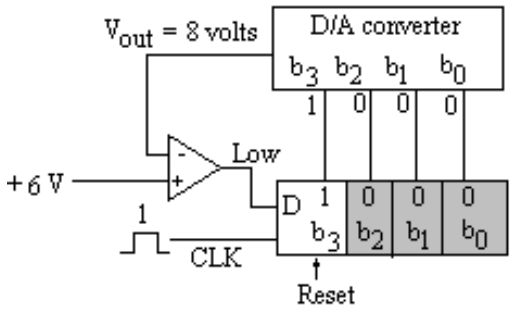
In order to understand the operation of this type of A/D converter, we will take a specific example of a four-bit conversion. Figure 13.22 (a through d) shows the step –by-step conversion of a given analog input voltage (say 6 volts). It is further assumed that D/A converter has the following output characteristics:

V_{out} = 8 volts for bit 3 (MSB or b_3)

V_{out}= 4 volts for bit 2 (2^{nd} MSB or b_2)

V_{out}= 2 volts for bit 1 (3^{rd} MSB or b_1)

V_{out}=1 volt for bit 0 (LSB or b_0)



(a)

(d)

Fig. 13.22

It is clear from these figures that after completing the conversion cycle. The binary code 0110 is retained in SAR, which is binary value of the input voltage (6Volts). It is finally displayed on the display devices.

13.9 COUNTER OR DIGITAL RAMP TYPE A/D CONVERTER

Another method of converting the analog signal to digital one is the counter or digital ramp type A/D converter which utilizes a binary counter to count a continuous pulse of standard width and height from a clock. The standard clock pulses are passed through a gate which is open for some time to allow these pulses to go to the input of counter. Normally the gate is closed and as soon as the start signal is applied a stair case voltage is initiated. This voltage is increased linearly with the increase of the binary counts in the counter. The gate remains open for the time the linear stair case voltage

becomes equal to the input analog voltage. The counter records the number of clock pulses which is proportional to the input analog voltage.

Figure 13.23 shows the schematic diagram of this type of A/D converter. The analog signal, to be converted to its equivalent digital output, is applied to one input of an operational amplifier being used as a comparator. When a start of conversion pulse is applied to the control unit it resets the binary counter and opens the gate. The counter

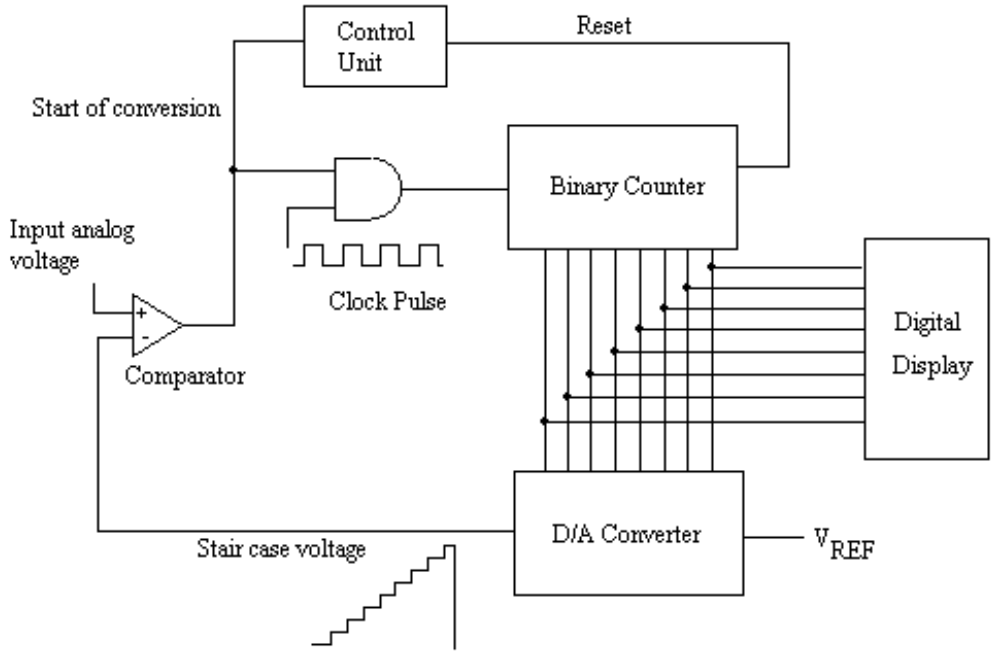

Fig. 13.23

starts counting the clock pulses which are of standard width and height. The output of the counter is fed to a D/A converter which produces an analog output (stair case voltage) in response to the digital signal (output of the counter) as its input. This analog output voltage is fed to the reference input of the comparator. So long as the input analog signal is greater than the stair case voltage the comparator provides the high output to the gate, the gate remains open and the clock pulses are allowed to reach to the input of the counter. These pulses are counted by the counter thus continuously increasing the digital output. The moment the analog output of D/A converter (stair case voltage) exceeds the input analog voltage, the comparator provides a low output disabling the gate and the counter stops counting. The binary number stored in the counter represents the digital output voltage corresponding to the input analog voltage. The digital output is displayed on the display devices.

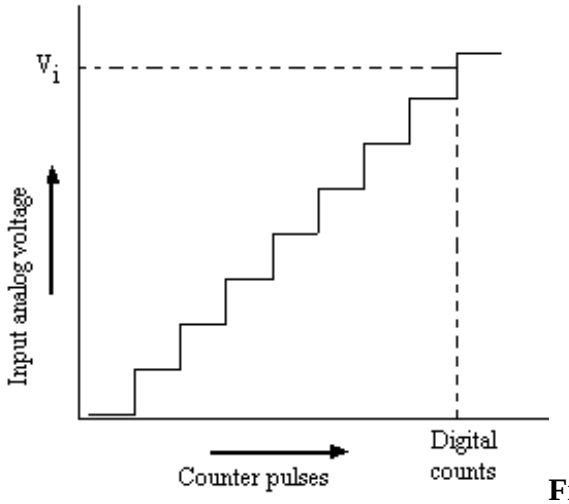

Fig. 13.24

For a steady input the digital output is as shown in figure 13.24. The output is represented by the number of clock pulses counted by the counter till the stair case voltage becomes equal to the input voltage. This method of conversion is slow; as for maximum input, the counter has to count from zero to maximum number of states for the comparison. For each conversion cycle the counter is to be reset and counting starts from beginning. The time of conversion is not important in d.c. or slow varying signals as the output waveform gives a good representation from which the input waveform can be constructed as shown in figure 13.25. But if the conversion time and the signal transient time are comparable the reconstructed digital output will not be correct. In this case it is necessary to reduce the conversion time by using faster D/A converter.

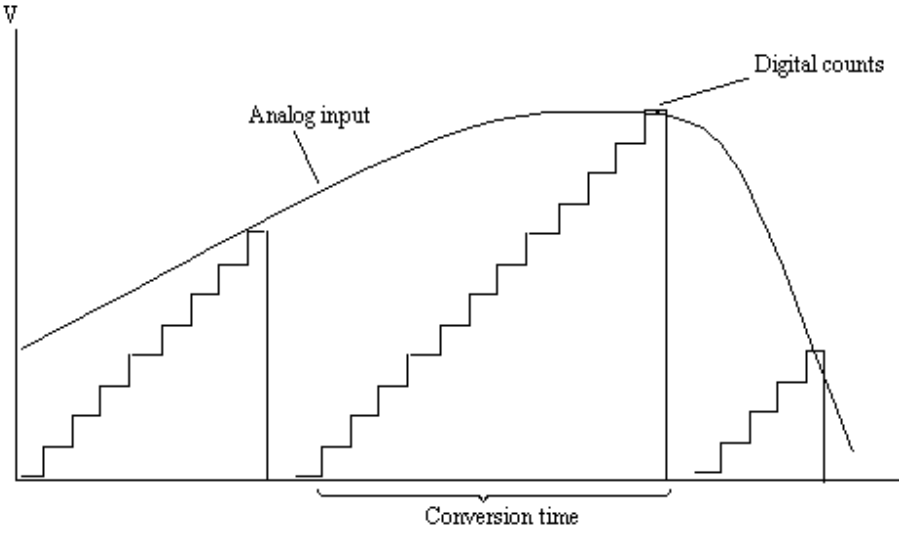

Fig. 13.25

A modification to this converter is possible if the resetting of the counter is avoided each time. For this purpose an up/down counter may be used in place of up

counter. The circuit shown in figure 13.26 illustrates this modification in which an

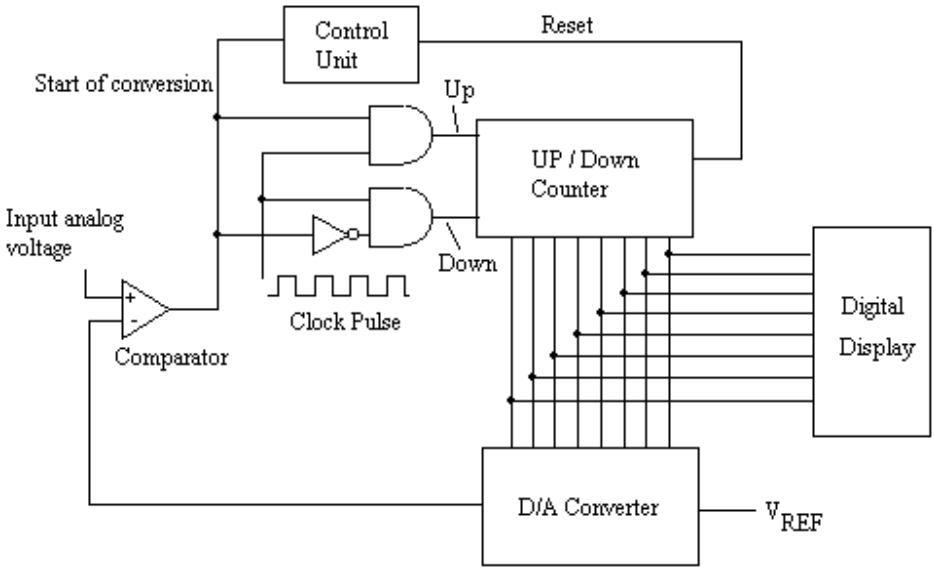

Fig. 13.26

up/down binary counter is used and the converter proceeds without resetting. The circuit is almost the same as the counter or digital ramp type A/D converter. The up/Down counter is operated by up or down signals from the control unit. The digital to analog converter output controls the output of the comparator. Till the D/A converter output is less than the analog input voltage, the up signal is enabled and the counter counts in forward direction. When the analog input falls, the down signal is enabled and the counter starts reverse counting giving an output corresponding to new analog input as shown in figure 13.27.

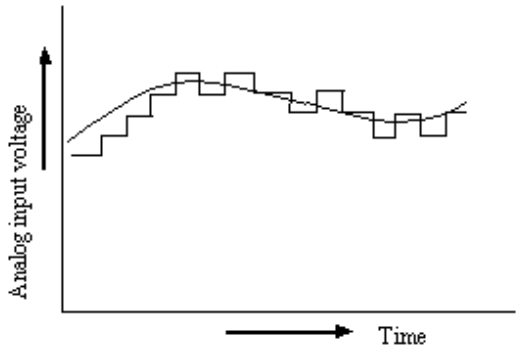

Fig. 13.27

13.10 SINGLE SLOPE A/D CONVERTER

This type of method is similar to counter or digital ramp type A/D converter. In this type of A/D converter also, a gate whose period is proportional to the amplitude of the analog sample is generated. For the generation of gate, the input analog voltage is compared with the output of an integrator. The output of integrator is a ramp voltage of constant slope. The standard clock pulses are passed through the gate and are counted by the counter. The gate remains open for the time proportional to the input analog signal. The recorded number of pulses is, therefore, the required digital output of the analog signal.

The schematic block diagram of such an analog to digital converter is shown in figure 13.28. Initially a reset pulse is applied which clears the counter and resets the integrator. The integrator produces a linearly rising ramp voltage, whose slope will depend on the values of the resistance R and capacitor C. The input analog voltage is compared by a comparator with the ramp voltage. As long as the integrator output is smaller than the input analog voltage, the comparator output is high. This high output enables the AND gate. The standard clock pulses are, therefore, allowed to pass through the gate which will be counted by the counter. When the ramp voltage becomes greater than the input analog voltage, the comparator changes the state thereby disabling the AND gate. The counter stops counting. It can easily be seen that the gate duration is linearly related to the magnitude of the input analog signal. Hence the count accumulated in the counter is a digital representation of the input analog voltage.

It may be mentioned here that the precision in the proportionality between the gate duration and the magnitude of the input analog signal depends upon the linearity of the ramp voltage obtained at the output of the operational amplifier. So the overall accuracy will depend upon the stability of reference source, the off-set of the operational amplifier, the frequency stability of the clock as well as the values of resistance R and capacitance C.

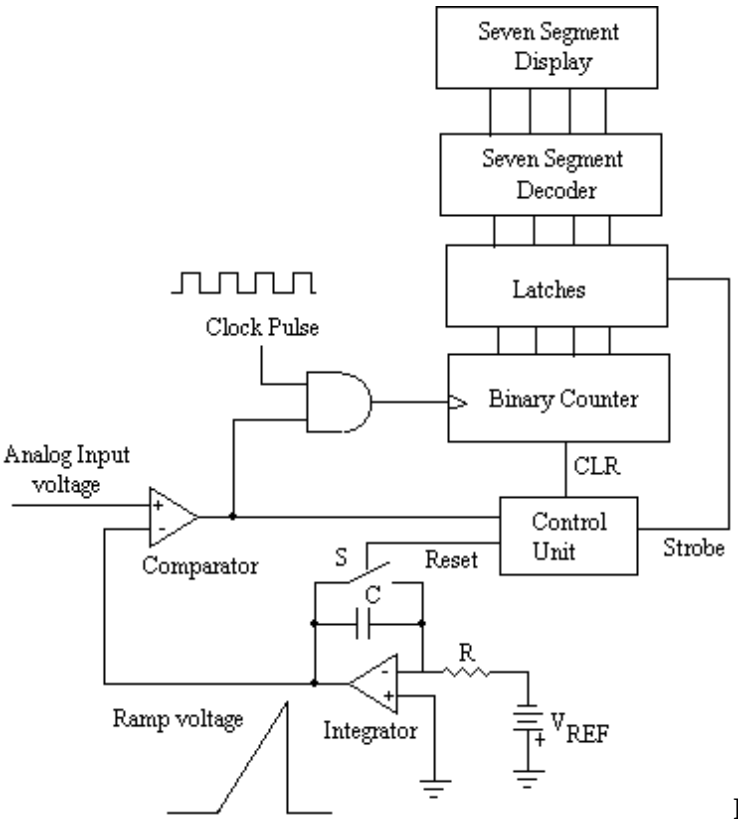

Fig. 13.28

13.11 DUAL SLOPE A/D CONVERTER

In single slope A/D converter, the accuracy of the converter depends on the linearity of the ramp voltage generated by the integrator. The linearity of ramp voltage, however, depends on the accuracy of the values of Resistance R and capacitance C of the integrator, whose values may vary with time and temperature. The dual slope analog to digital converter utilizes two different ramps, one for fixed time and other for fixed slope. It is very popular and widely used D/A converter because it has the slowest conversion time and relatively low cost. This method offers good accuracy, good linearity, and very good noise rejection characteristics.

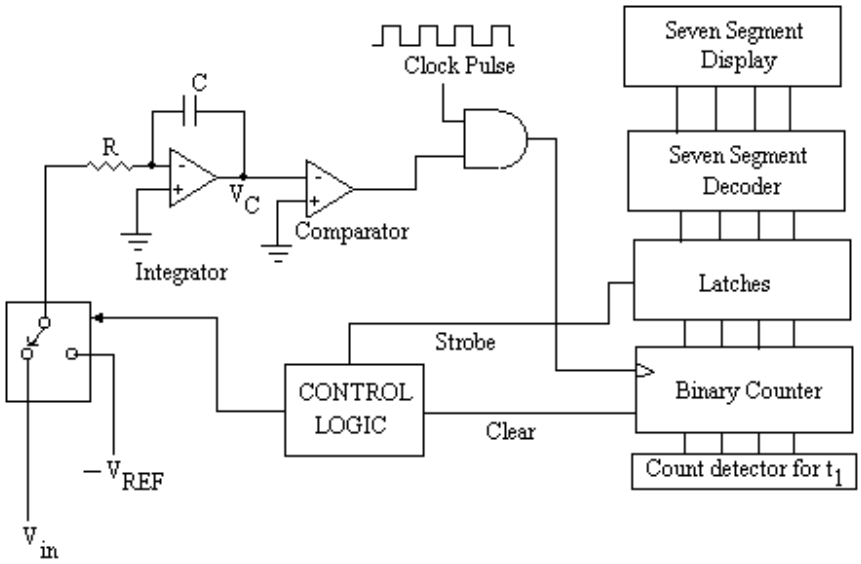

Fig. 13.29

The logic diagram of the dual slope A/D converter is given in figure 13.29. This converter is similar to that of the single slope A/D converter. In this converter, the integrator forms two different ramps, one for fixed time and other for fixed slope. The capacitor of the integrator is first charged with constant current obtained from input analog voltage for fixed time then the capacitor is discharged for fixed slope through other constant current obtained from a reference voltage source. The basic operation of this converter can be understood as follows:

This converter consists of standard clock pulses applied to the gate. The gate allows the pulses to the input of the counter which counts these pulses. Initially all the counters are reset to 0's and ramp too is reset to zero. Now the control logic allows switch S to connect the input analog voltage V_{in} to the integrator circuit. A constant current equal to $\frac{V_{in}}{R}$ flows through the capacitor C as the inverting input of the operational amplifier of the integrator is at virtual ground. The capacitor C will charge linearly with this constant current. This results a negative going ramp at the output of the integrator. The comparator's output will be positive which allows the clock pulse to pass through the AND gate to the input of the counter. This ramp is allowed for fixed time say t_1. The actual time t_1 is determined by the count detector. The voltage V_C at the output of the integrator is given by:

$$V_C = -\frac{1}{R.C}\int_0^{t_1} V_{in}.dt$$

$$= -\frac{1}{R.C}.V_{in}.t_1 \qquad \ldots (13.6)$$

The counter when reaches the fixed count at t_1, the control logic generate a pulse to clear the counter to zero and the switch S connects the integrator input to a negative reference voltage ($-V_{REF}$). The capacitor C of the integrator starts discharging linearly due to the constant current from $-V_{REF.}$ The integrator thus produces a positive going ramp beginning at $-V_C$ and increases steadily till it reaches to 0 volt as shown in figure 11.29. At this time the counter is counting. The conversion cycle ends when $V_C = 0$ volt; the comparator produces the low state, which disables the gate and counter stops counting.

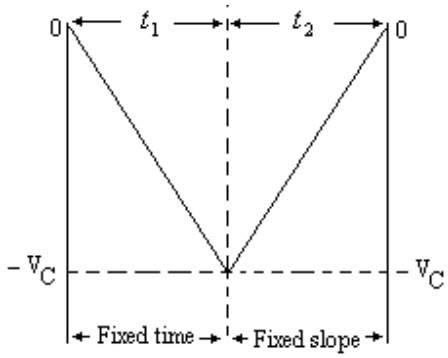

Fig. 13.30

Let t_2 is the time when the output of integrator becomes zero, so the output of the integrator is given by:

$$V_C = \frac{V_{REF}}{R.C}.t_2 \qquad \ldots (13.7)$$

Since the integrator's output beginning at 0 volt and integrates down to $-V_C$ and then integrate back to 0 volt, so the equations (13.6) and (13.7) may be equated as:

$$\frac{V_{in}}{R.C}.t_1 = \frac{V_{REF}}{R.C}.t_2$$

or
$$V_{in} = V_{REF}.\frac{t_2}{t_1} \qquad \ldots (13.8)$$

In this equation V_{REF} and time t_1 are constants, so

$$V_{in} \propto t_2 \qquad \ldots (11.9)$$

This equation is independent of the values of resistance R and capacitance C. Further at the end of conversion cycle, the counts measured by the counter are proportional to the input analog signal are latched to display on the display devices.

13.12 ADC 0808/0809

The ADC 0808/0809 is an 8-bit A/D converter with 8-channel multiplexer which can be interfaced with the microprocessor. It is the most popular, inexpensive and widely

used A/D converter. It is a monolithic CMOS device which uses the method of successive approximation A/D converter. It does not require external zero and full scale adjustment. The device operates with + 5 V d.c. supply. The conversion time is 100 μsec at clock frequency of 640 KHz. The 8-channel multiplexer can directly access any of the 8 single ended analog signals.

The ADC 0808 / 0809 offers following features:

- High speed
- High accuracy
- Minimal temperature dependence
- Excellent long term accuracy and repeatability
- Consume minimal power

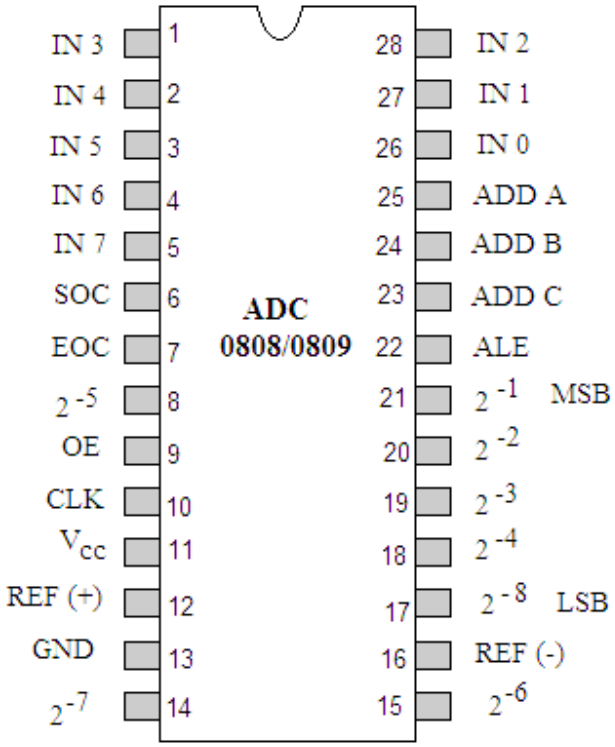

Fig. 13.31

The pin diagram and schematic block diagrams of this IC ADC 0808 / 0809 are shown in figures 13.31 and 13.32 respectively. The pin description of this IC is given as:

Pins 26-28 and 1-5 – are 8 input channels IN0 – IN7 (multiplexed), which are selected by the three (address) lines ADD A, ADD B and ADD C.

Pin 6 SOC – Start of conversion pin. A high to this pin starts the conversion.

Pin 7 EOC – End of conversion. This an output terminal and gives high signal when the conversion ends.

Pins 21-18, 8, 15-14 & 17 8-bit output (latch) pins to be connected to the port of 8255.

Pin 9 OE – Output enable pin which is connected to the positive supply.

Pin 10 CLK – Clock terminal. It is to be connected either to the external clock of frequency between 10 to 1280 KHz or the clock out frequency of the 8085A after dividing it by a factor of four may be connected to this pin.

Pin 11 V_{CC} – Supply pin (+5 V).

Pin 12 Ref (+) – Reference pin which is to be connected to the + supply.

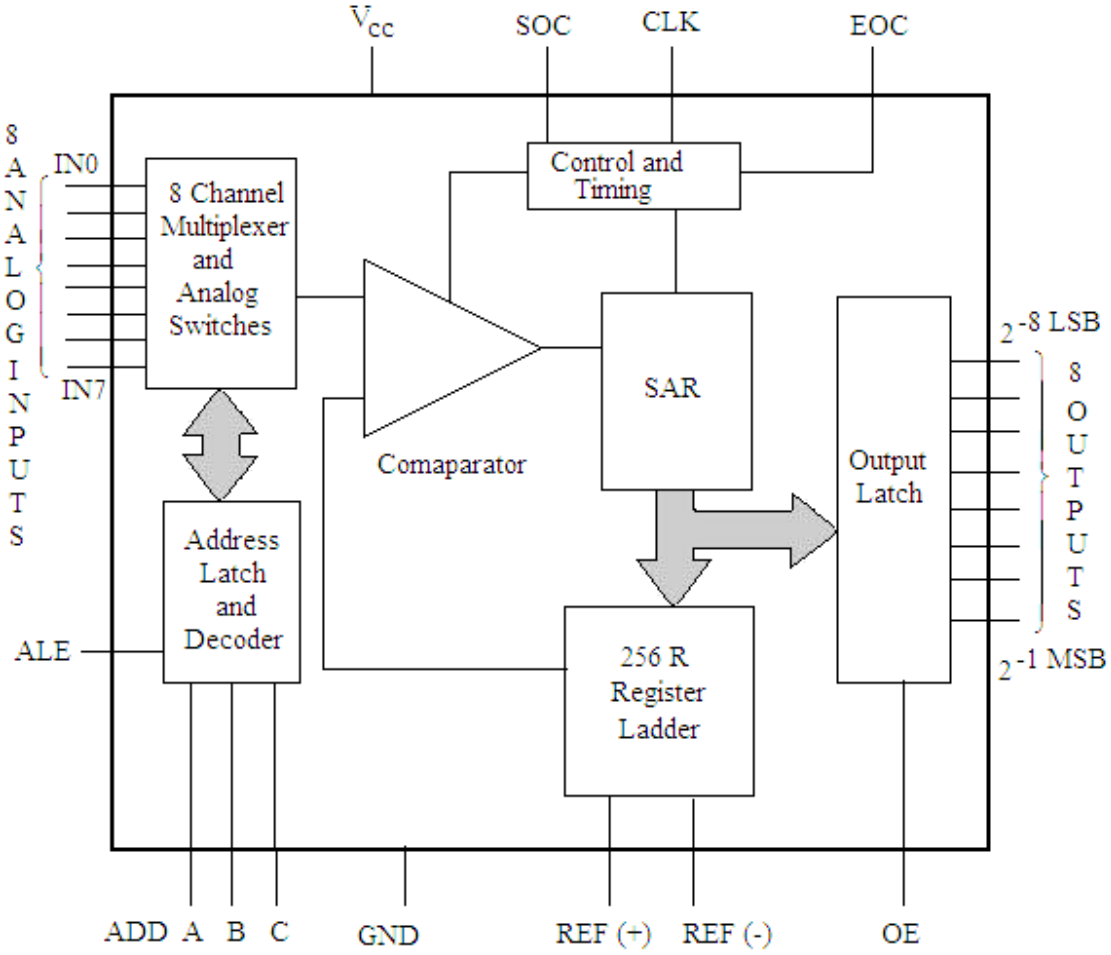

Fig. 13.32

Pin 13 GND – Ground terminal.

Pin 16 Ref (-) – Reference pin to be connected to the ground.

Pins 25-23 – Address pins (ADD A, ADD B and ADD C). These pins are used to select the channels as given below (Table 13.4):

Table 13.4

Channels Selected	Address lines		
	C	B	A
IN0	0	0	0

IN1	0	0	1
IN2	0	1	0
IN3	0	1	1
IN4	1	0	0
IN5	1	0	1
IN6	1	1	0
IN7	1	1	1

The timing diagram of this IC is shown in figure 13.33.

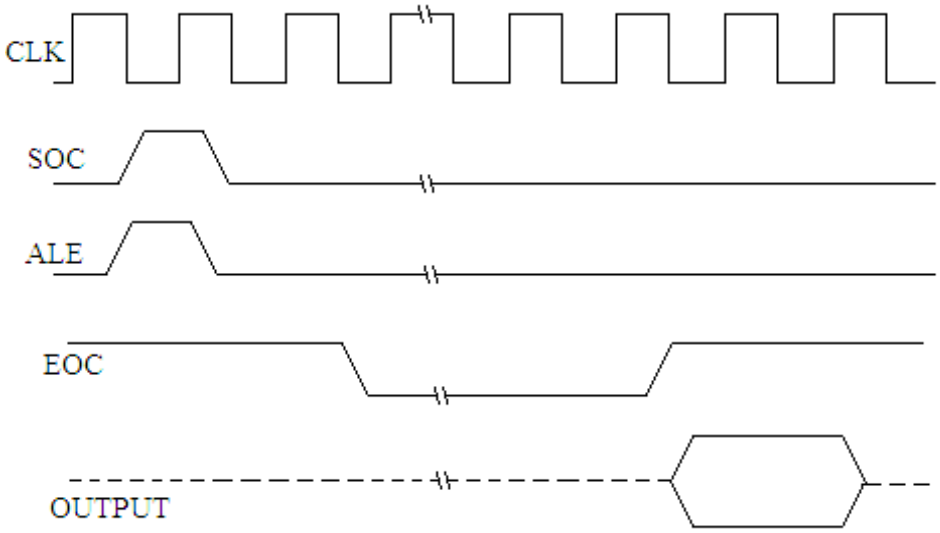

Fig. 13.33

The interfacing connection of ADC 0808 / 0809 with the microprocessor 8085A is shown in figure 13.34. In this circuit an analog voltage, whose equivalent digital value

is to be obtained, is applied to IN0. The output terminals of the ADC are connected to

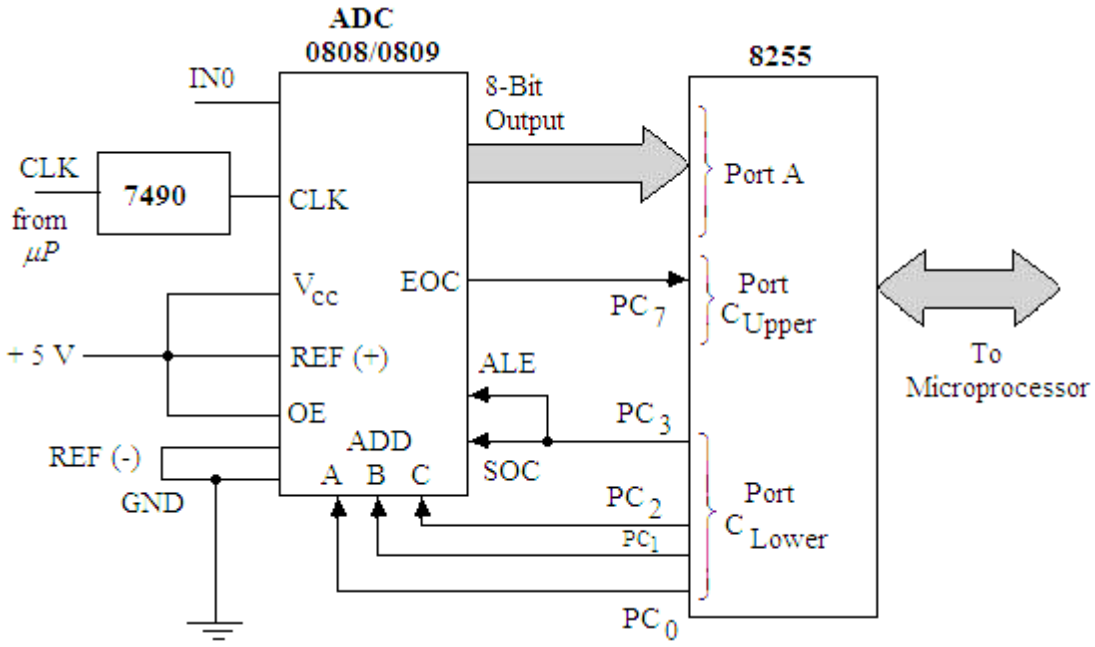

Fig. 13.34

Port A of 8255 PPI. This port is to be used as the input port. The PC_7 terminal of the Port C_{Upper} is connected to the End of Conversion terminal of the ADC. This port is also used as the input port. The port C_{Lower} is used as the output port. The three terminals PC_0 to PC_2 are connected to the three address pins of the ADC 0808 / 0809 for the selection of input channel. The PC3 terminal is connected to the SOC (Start of Conversion) and the ALE terminals of the converter. The OE and REF (+) terminals are connected to the + 5V supply. The assembly language program is given below:

In the above circuit diagram, the channel used is IN0, so for its selection we have:

C	B	A	
PC_2	PC_1	PC_0	
0	0	0	= 00 H

To enable the start of conversion first PC3 is made high and then low without changing the selection of channel, we proceed as follows:

PC_3	PC_2	PC_1	PC_0	
1	0	0	0	=08 H
PC_3	PC_2	PC_1	PC_0	
0	0	0	0	=00 H

PROGRAM

Label	**Mnemonics**	**Operand**	**Comments**
	MVI A,	98 H	; Initialize 8255-I to work Port A and Port C_{Upper} as input ports, and port C_{Lower} as output port.

```
        OUT     03 H    ; Write the control word in the
                          control word register of 8255-I.
        MVI  A, 00 H    ; Load accumulator with 00H.
        OUT     02 H    ; 00H is sent to Port C_Lower to select
                          IN0 channel.
        MVI  A, 08 H    ; Load 08 H to accumulator.
        OUT     02 H    ; ALE and SOC are enabled (high).
        MVI  A, 00 H    ; Load 00 H to accumulator.
        OUT     02 H    ; ALE and SOC will be low. A
                          pulse is applied from high to low
                          for the conversion through PC3
                          without affecting the channel
                          selected.
READ    IN      02 H    ; Read End of conversion (PC7).
        RAL             ; Rotate left to check if PC7 is one.
        JNC     READ    ; If not 1 READ again.
        IN      00 H    ; Read digital output of the A/D
                          converter.
        STA     2100 H  ; Store the result in 2100 H memory
                          location.
        HLT             ; Stop processing.
```

After the execution of this program, the values stored in the memory location 2100 may be checked.

Analog Voltage	Digital output
0 V	00 H
1 V	34 H
1.4 V	47 H
2 V	6D H
2.8 H	90 H
3 V	94 H
4 V	CE H
5 V	FF H

13.13 A/D CONVERTER USING D/A CONVERTER AND SOFTWARE

The A/D converter can also be realized using the D/A converter and the software. For this purpose the software is used to implement successive approximation A/D converter. Figure 13.35 shows the interfacing connection for this. The input analog voltage is applied to a comparator. This voltage is compared by the output of the D/A converter. The output of the comparator is sensed by the microprocessor through the PC_7 of the 8255. A digital input is applied to the D/A converter, through port A of 8255.

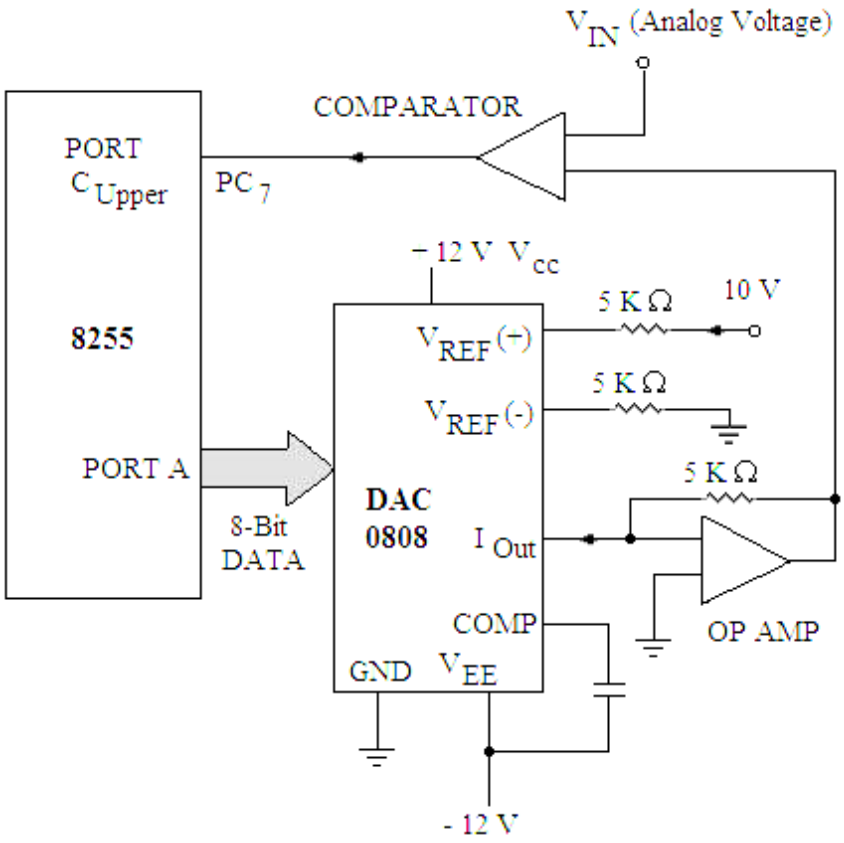

Fig. 13.35

The microprocessor first applies 00 H as the digital input to the DAC 0808 and checks through PC_7 for high signal. If a high pulse does not appear at the output terminal of the comparator, the microprocessor increments the digital input by 1 and the process is repeated till a high signal appears at the output of the comparator. As a high signal appears the microprocessor stops successive approximation and the corresponding digital input value is stored in the memory location. This digital value is equivalent to the analog signal applied at V_{IN} terminal of the comparator. The software for the same is given as:

PROGRAM

Label	**Mnemonics**	**operand**	**Comments**
	LXI SP,	XXXX H	; Initialize stack pointer.
	MVI A,	88 H	; Initialize 8255-I to work Port A, Port B and port C_{Lower} as output ports, and Port C_{Upper} as input ports.
	OUT	03 H	; Write the control word in the control word register of 8255-I.
	MVI A,	00 H	; Load accumulator with digital input to send it to D/A converter.
LOOP	OUT	00 H	; The digital input is sent to D/A converter through Port A.
	PUSH PSW		; Save PSW

```
        CALL    DELAY   ; Call delay subroutine program.
        IN      02 H    ; Check the output of the comparator through PC7, Read PC7 bit.
        RAL             ; Rotate left to check PC7, if it is high.
        JC      NXT     ; If is high go to NXT.
        POP  PSW        ; Else get the digital value from the stack.
        INR  A          ; Increment digital value.
        JMP     LOOP    ; Jump to LOOP.
NXT     POP  PSW        ; Get the digital value from the stack.
        STA     2100 H  ; Store the result in 2100 H memory location.
        HLT             ; Stop processing.
```

SUBROUTINE PROGRAM:

```
Label     Mnemonics   Operand   Comments
DELAY     LXI D,      0002 H  ; Loads DE register pair with a 16-bit number.
LOOP1     DCX  D              ; Decrements DE register pair by one.
          MOV  A,     E       ; Moves the contents of E register to accumulator.
          ORA  D              ; ORing of the contents of D and E registers are performed to set the zero flag.
          JNZ       LOOP1     ; If result ≠ 0 jump to loop1
          RET                 ; Go back to main program.
```

After the execution of this program, the values stored in the memory location may be checked for the input applied voltage.

Analog Input	Digital output
0 V	00 H
2.5 V	40 H
5 V	80 H
10 V	FF H

PROBLEMS

1. Discuss the resistive divider D/A converter. Find the general expression for the output voltage of a resistive divider network.
2. Using the resistive divider network draw the circuit of a 6 bit D/A converter and explain its operation. What are the drawbacks of this D/A converter?
3. Show that the outputs of a binary weighted resistor network are directly proportional to the binary inputs.
4. Draw the schematic diagram of a resistive divider D/A converter. Explain its operation. Mention the drawbacks of this converter.

5. A 5 bit resistive divider network has 0 volts full scale output, find the output voltage for a binary input 10101. (Ans. 6.774 V)
6. A 6 bit resistive divider D/A converter has resistance of 100 KΩ in MSB branch. The reference voltage is 15 V. The resistance in the feed back path of the operational amplifier is 39 KΩ. What is the output voltage for the binary input 101101? (Ans. – 8.22V)
7. For a 6 bit resistive divider network, the reference voltage is 10 V, find the following:
   (i) Full Scale output voltage.
   (ii) The analog output voltage for a digital input of 010011.
   (iii) The output voltage change due to least significant bit.
   (Ans.:10V, 3.02 V, 0.16 V)
8. Draw the schematic diagram of a binary ladder D/A converter. Explain its operation. Mention its merits and demerits.
9. Find the expressions for the output due to MSB and second MSB of a 4-bit binary ladder network.
10. Discuss the binary ladder D/A converter. Find the general expression for the output voltage of a binary ladder network.
11. What are the performance criteria for the D/A converter? Discuss their importance while selecting a D/A converter.
12. For a 6-bit binary ladder D/A converter the input levels are 0 = 0 V and 1 = 10 V, find
    (i) The output voltages caused by each bit.
    (ii) The output voltage corresponding to an input of 101101.
    (iii) The full scale output voltage of the ladder.
    (Ans. (i) -5V, -2.5 V, -1.25 V, -0.625 V, -0.3125 V, -0.15625 V (ii) – 7.03125 V (iii) – 9.84 V)
13. For a 5-bit binary ladder D/A converter the input levels are 0 = 0 V and 1 = 10 V, find the output voltage corresponding to binary input of (i) 10111 (ii) 01101.
    (Ans. – 7.1875 V, – 4.0625 V)
14. What is the step size (or resolution in volts) of a 10 bit D/A converter, if the full scale output is +10 volts? Find the percentage resolution also.
    (Ans. 9.78 mV, 0.0978%)
15. How many bits are required at the input of a D/A converter to achieve a resolution of 15mV, if the full scale output is 15 volts?
    (Ans. 10 bits)
16. Give the details of D/A converter IC 0808. Using this IC draw a circuit diagram to get the analog output voltage corresponding to 8 bit digital input.
17. Describe how the interfacing of the D/A converter is done with the microprocessor 8085A. Give its circuit diagram.
18. Discuss the simultaneous A/D converter to convert 0 to V volts analog voltage to 3 bit digital output. Draw the logic diagram also. What are the disadvantages of this type of A/D converter?
19. Give the details of the microprocessor compatible D/A converter IC AD558.
20. Draw a logic diagram to convert 0 to V volt analog voltage to its equivalent 2 bit digital output using simultaneous A/D converter.

21. Describe the successive approximation method for A/D conversion.
22. Draw a schematic diagram of counter or digital ramp type A/D converter. Explain its operation.
23. Describe the modified counter or digital ramp type A/D converter with neat diagram.
24. Draw a schematic diagram of a D/A converter. Explain its operation.
25. Describe single slope A/D converter with it logic diagram. Mention its merits and demerits.
26. Describe Dual slope A/D converter with it logic diagram.
27. Give the details of A/D converter IC 0801.
28. The input bits of the D/A converter is connected to the output pins of Port A of 8255, which is already connected with the microprocessor (ref. fig.13.13). Write a program to generate stair case voltage with ten steps. It should have the constant pulse duration.
29. Write a program to generate square wave of 2 KHz frequency with a peak voltage of 2.5 volts. Use D/A converter (ref. fig. 13.13) for this purpose. The square wave should be available at the output of the converter.
30. Give the details of A/D converter IC ADC0808/0809. Using this IC draw a circuit diagram to get the digital value of the input analog voltage.
31. Describe how the interfacing of the A/D converter is done with the microprocessor 8085A. Give its circuit diagram.
32. Write a program to get the digital output of an analog signal applied to ADC 0808/0809 interfaced with the 8085A. The input analog signal is applied to the channel 3 of this IC.
33. Explain how the A/D converter can be designed using D/A converter and the software. For this purpose the software is used to implement successive approximation A/D converter.

14

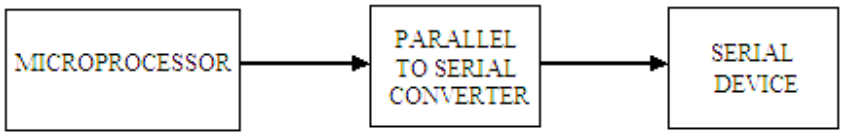
Serial Communication and Programmable Communication Interface

In continuation to the series of interfacing devices, the discussion will now be made on serial data communication and programmable communication interface, since the serial data transmission is always preferred for long distance transmission. Though the serial data transmission can be made through the SID (serial input data) and SOD (serial out data) lines of 8085A microprocessor, but it requires suitable software for the data transfer. Moreover, most of the microprocessors do not have the provision of SID and SOD lines. Apart from this, it can not offer high baud rate. Hence this chapter will deal the detailed discussion on serial communication and most powerful programmable communication interface IC 8251.

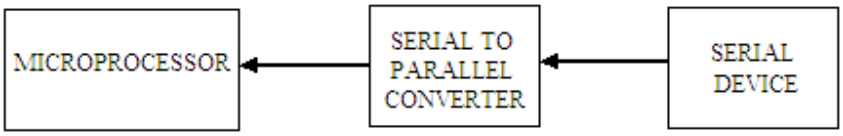
14.1 SERIAL DATA COMMUNICATION

There are two types of data communication, Parallel and Serial data communications. In parallel data communication each bit of a word is to be transmitted on a separate line along with a common ground line. In the 8085A microprocessor the data to be transmitted is of 8 bits. This parallel data transmission is not recommended for long distance communication as large number of data lines is needed. In serial data transmission, data is transmitted bit by bit either from the microprocessor to I/O devices or vice-versa. There are certain input/output devices in the microprocessor based systems, which only accept the serial data. The common I/O devices for such a data communication are CRT terminals, printers, cassette recorders etc. The microprocessors thus have the provision for transferring the data in the serial fashion. In such I/O devices, a parallel to serial conversion is required for the data transfer from the microprocessor to the peripheral device (figure 14.1a). Similarly, a serial to parallel conversion is required in transmitting the data from the peripheral device to the microprocessor (figure 14.1b).

As already discussed, the 8085A microprocessor has the provision of SID and SOD lines for the serial data transfer between the microprocessor and I/O devices. But it requires the software. Moreover, most of the microprocessors do not have the provision of these SID and SOD lines. Apart from this, it can not offer high baud rate. So, serial data communication is generally used for the long distance communication with high baud rate. Further, it requires less number of lines for the data transmission.



(a)



(b)

Fig. 14.1

The serial communication occurs either in the following two formats:

- Synchronous
- Asynchronous

In synchronous format, a receiver and a transmitter are synchronized. In this format the data is divided into fairly large blocks, typically 1000s of bytes. A block of characters is transmitted along with the synchronization information. The synchronizing signals are added once before each block. The synchronization characters mark the beginning of the transmission. This format is generally used for high baud rate (more than 20 K bits/second). The baud rate is defined as the number of bits transmitted or received per second. Figure 14.2 illustrates this format.

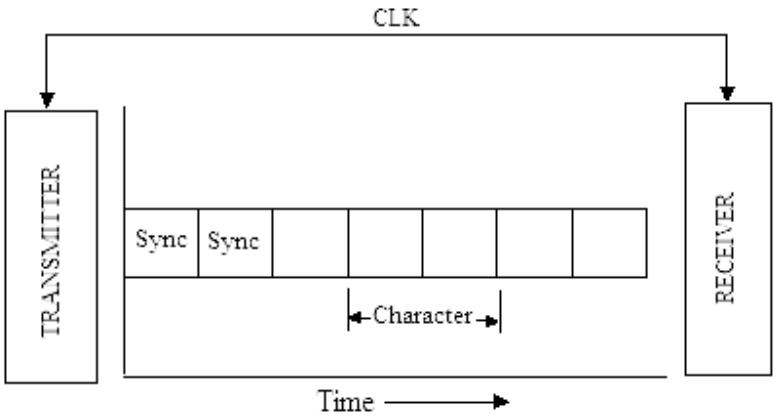


Fig. 14.2

In asynchronous format, timing signals are added to each character of data. A START bit is added at the beginning of each character. A STOP bit is added at the end of the character data. A low signal is used for the START bit and a high signal is used for STOP bit. When no data is being transmitted, a receiver stays high, called **MARK**. The process of adding start and stop bits to a character is known as **FRAMING**. The asynchronous format is generally used for low speed transmission. This format is illustrated in figure 14.3.

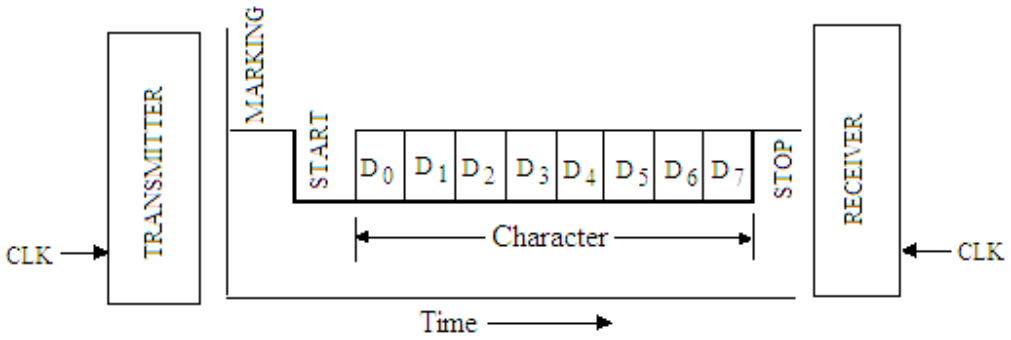

Fig. 14.3

The serial mode of data transfer can be divided into three groups namely:

Simplex Method

Duplex Method

Half Duplex Method

In simplex method data transfer takes place in unidirectional i.e. either from the system to the I/O devices or from I/O devices to the system, of course through the serial link. A typical example is the transmission from a system to a printer.

In the duplex method data transfer takes place in both the directions. However, if the transmission goes one way at a time, it is called half duplex; if it goes both ways simultaneously, it is called full duplex. The walkie talkie is an example of half duplex and the communication between the computers is an example of full duplex.

14.2 MODEM

One of the most common applications of the serial transmission would be data transmission between large computers. For such serial digital transmission the existing telephone lines are used. The telephone lines are designed to carry analog signals in the range of 40 Hz to 4 KHz. These lines will not readily support digital signals. Therefore, the digital data is to be converted into audio frequency format. A device that can convert the digital value in the form of the audio signal has to be used because the basic binary bits can not be placed directly on these lines. Such a device is known as MODEM (**MOD**ULATOR- **DEM**ODULATOR). The modem is be used at both the ends; at the

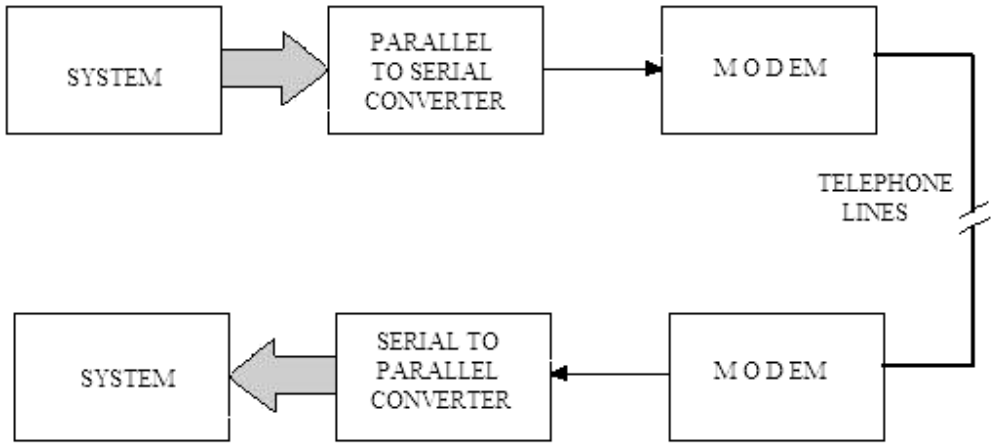

Fig. 14.4

receiving end as well as at the transmitting end. The modem at the transmitting end converts digital signal into analog signal format (audio frequency range) and at the receiving end the modem converts audio signal back to the digital data.

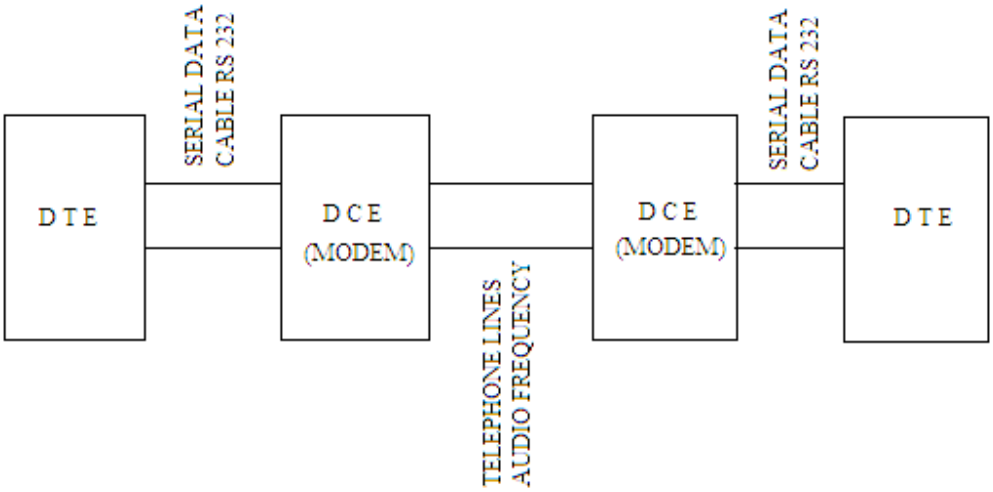

Fig. 14.5

Modems often use frequency shift keying technique for the conversion. It converts a 1 level signal into an audio signal of 1200 HZ and 0 level into audio signal of 2200 Hz. These converted audio signals are modulated on the carrier and then transmitted to the telephone lines. However at the receiving end another modem is used to convert the audio signal back to digital form. Figure 14.4 shows the block diagram of such transmission system. The originators and receptors of the digital data are called Data Terminal Equipments (DTE) and the modem units are called Data Communication Equipments (DCE). Figure 14.5 shows the modem connections using telephone lines.

14.3 SERIAL COMMUNICATION STANDARD

There are primarily two standards for transmitting the information in serial form. All the serial I/O devices work on either of these standards.

- Current Loop
- Voltage standard

In a current loop method, the current flows through the lines for the logic 1 and no current flow for the logic 0.

The two standards for the current loop are:

20 milliampere loop
60 milliampere loop.

A current loop reduces noise pickup and is suitable for long distance transmission.

The other standard is the voltage signal. When the data is transmitted as voltage, the commonly used standard is known as RS 232C. It is defined in reference to DTE (Data Terminal Equipment) and DCE (Data Communication Equipment) – terminal and Modem as shown in figure 14.6, which illustrates the connections of DTE to DCE. This standard was developed before the existence of TTL logics; its voltage levels are not compatible with TTL logic levels.

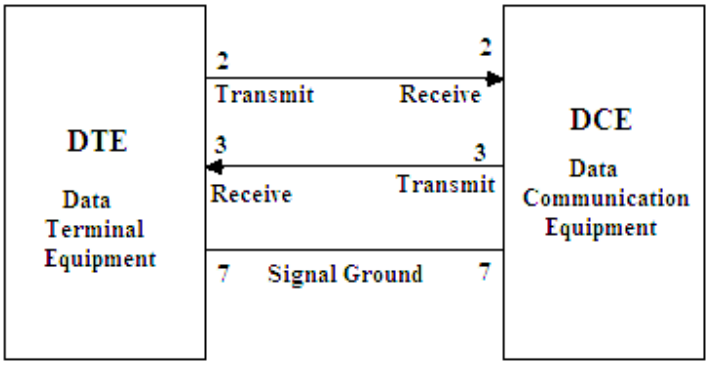

Fig. 14.6

RS 232C

Figure 14.7 shows the RS 232C 25-pin connector. The signals are divided into four groups namely:

- Data Signals
- Control Signals
- Timing Signals
- Ground

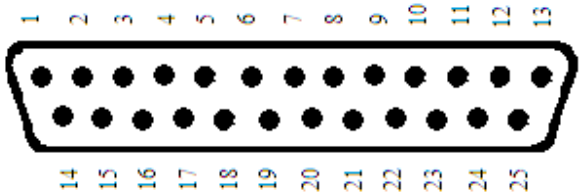

Fig. 14.7

The pin assignments are given below:

Pin 1: Protective Ground
Pin 2: Transmitted Data (T x D) → DCE
Pin 3: Received Data (R x D) → DTE
Pin 4: Request to Send (RTS) → DCE
Pin 5: Clear to Send (CTS) → DTE
Pin 6: Data Set Ready → DTE
Pin 7: Signal Ground
Pin 8: Received Line Signal Detector
Pin 9: Reserved for Data Set Testing
Pin 10: Reserved for Data Set Testing
Pin 11: Unused
Pin 12: Secondary Received Line Signal Detector
Pin 13: Secondary Clear to send
Pin 14: Secondary Transmitted Data
Pin15: Transmission Signal Element Timing (DCE Source)

Pin 16: Secondary Received Data
Pin 17: Receiver Signal Element Timing (DCE Source)
Pin 18: Unused
Pin 19: Secondary Request to Send
Pin 20: DCE ⟵ Data Terminal Ready (DTR)
Pin 21: Signal Quality Detector
Pin 22: Ring Indicator
Pin 23: Data Signal Rate Selector (DTE/DCE Source)
Pin 24: Transmit Signal Element Timing (DTE Source)
Pin 25: Unused

Technically the RS232C has -3V to -12V for logic '1' and +3V to +12V for logic '0'. This is negative logic. Because of incompatibility with TTL logic, voltage translator called line drivers and line receivers are required to interface TTL logic with RS232 signals. As shown in figure 14.6, the minimum interface requires three lines: pins 2, 3 and 7. These lines are defined in relation to the DTE; the terminal transmits on pin 2 and receives on pin 3. On the other hand, the DCE transmits on pin 3 and receives on pin 2.

The comparative study of synchronous and Asynchronous modes of data transfer to and from the serial I/O devices is given in table 14.1.

Table 14.1

Sr. No.	Format	Serial Transmission	
		Synchronous	**Asynchronous**
1.	Data format	Groups of characters	One character at a time.
2.	Framing	Synchronous characters are sent with each group.	START and STOP bit/bits are sent with each character.
3.	Speed	High speed, 20 K bits/sec or more.	Low, Less than 20 K bits/sec.
4.	Distance for communication.	Recommended for long distance communication.	Recommended for small distance communication.
5.	Implementation	Hardware.	Hardware or Software.
6.	Data direction	Simplex, half and full duplex.	Simplex, half and full duplex.

The computer communicates with the serial I/O devices either in Asynchronous or Synchronous modes. Here the discussion will be made on the Asynchronous mode of serial data transfer, as it is both hardware and software implemented.

14.4 ASYNCHRONOUS SOFTWARE APPROACH

In this case, the framing of each character is done by introducing START and STOP bits using the software. The data in parallel form is available with the microprocessor to be transmitted to serial I/O devices. The data is then converted to serial form using the software and sent to the serial I/O devices through an interfacing circuit. The interfacing circuit is to be designed for the microprocessor 8085A microprocessor is shown in figure 14.8. This circuit consists of D-type flip-flop (IC 7475) whose device address is chosen to be FF H. The address bus is decoded using an 8-inpout NAND gate (IC 7430), and combined with the control signal $\overline{IOW}$ to clock the latch. When the instruction OUT FF H is executed, the clock goes high and bit at the D_{IN} terminal is transferred to output Q of the flip-flop. The bit is latched as the clock goes low. If the Q is high 20 mA current flows through the TTY (Tele Type) circuit.

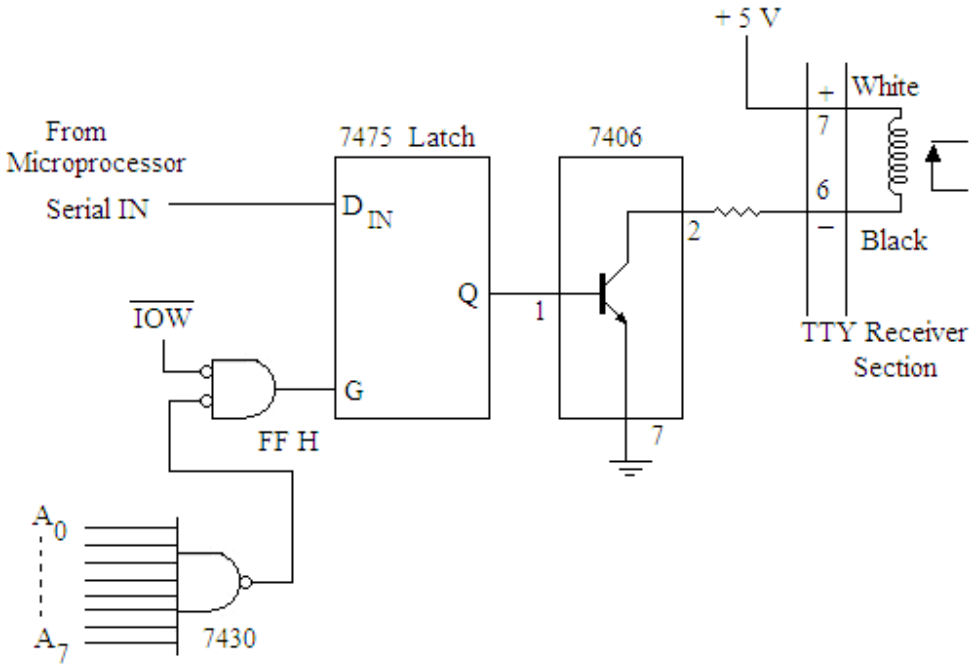

Fig. 14.8

Let us consider, a message is to be transmitted to teletype (TTY) using the 8085A microprocessor. The interfacing circuit, shown in figure 14.8, is used for this transmission. The characters of the message are stored in the memory locations starting at 2101 H. Each character includes framing information (START and STOP bits). Each character has 11 bits for the transmission; 8 bits for ASCII character, one START bit and two STOP bits. .Let the first character of the message is **W** (ASCII code for W is 57 H). Figure 14.9 shows a stream of eleven bits for this first ASCII character of the message. The character bits are transmitted beginning with the least significant bit (LSB) D_0. The

bit time, the delay between two successive bits, is determined by the transmission rate (baud rate).

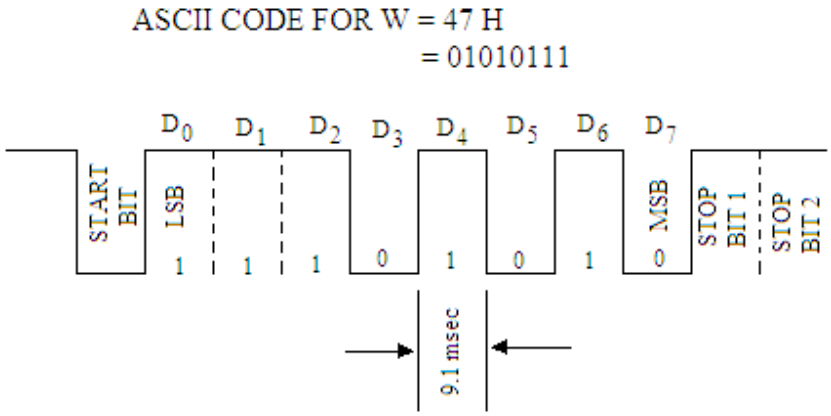

Fig. 14.9

A typical (TTY) sends (or receives) 10 ASCII characters per second. If each character has 11 bits, then TTY transmits 110 bits/second.

TTY transmission rate = 110 bits/second

Time for each bit $= \frac{1\text{sec}}{110}$

= 9.1 msec.

Therefore, microprocessor should send bit by bit information (including framing bits) to TTY to transmit the bit a time interval of 9.1 msec.

For the transmission the necessary software for 8085A is given as:

PROGRAM

Label	**Mnemonics**	**Operand**	**Comments**
	LXI SP,	XXXX H	; Initialize Stack pointer.
	LXI H,	2101 H	; Initialize H-L register pair for index pointer.
	MVI A,	01 H	; Set up MARK bit as 1.
	OUT	FF H	; Goes to the output of Flip-flop, whose address is FF H.
NXT	MOV A,	M	; Accumulator is loaded with the character of the message.
	CPI	0D H	; Compare if the character is Carriage return (0D H is the ASCII Code of carriage return).
	MOV B,	A	; Save the character in register B.
	JZ	END	; If the character is Carriage return, jump to END.

```
        CALL    SERIAL      ; Else Call subroutine for converting
                            into the serial form of the
                            character.
        INX H               ; Point to next character of the
                            message.
        JMP     NXT         ; Jump for next character.
END     CALL    SERIAL      ; Call subroutine for converting into
                            the serial form of the character
                            'Carriage return'.
        MVI B,  0A H        ; Load the character of Line feed
                            (0A H is the ASCII code for line
                            feed).
        CALL    SERIAL      ; Transmit line feed serially.
        HLT                 ; Stop Processing.
```

SUBROUTINE PROGRAM:

This is the subroutine for the conversion of bit of a character into serial form and then transmits to a TTY with a baud rate of 110.

```
Label   Mnemonics   Operand     Comments
SERIAL  MVI C,      08 H        ; Load register C with 08 H, which
                                is used as counter.
        MVI A,      00 H        ; Load START bit.
        OUT         FF H        ; Send the start bit at the output of
                                the flip-flop.
        CALL        DELAY       ; Call delay subroutine which
                                introduces a time delay of 9.1 msec
                                after START bit.
        MOV A,      B           ; Load the character into the

        MVI A,      01 H        ; Introduce STOP bit.
        OUT         FF H        ; STOP is sent to the output of the
                                flip-flop.
        CALL        DELAY       ; Call delay subroutine which
                                introduces a time delay of 9.1
                                msec.
```

```
        CALL    DELAY       ; Call delay subroutine which
                            introduces a time delay of 9.1
                            msec.
        RET                 ; Go back to main program.
```

Delay Program may be written for the time delay of 9.1 msec.

Similar, circuit and software may be used for the reception of the messages in the serial fashion.

The RIM and SIM instructions can also be used for the transmission and reception of data in serial fashion.

14.5 PROGRAMMABLE COMMUNICATION INTERFACE

Many types of UART (Universal Asynchronous Receiver Transmitter) and USART (Universal Synchronous/Asynchronous Receiver Transmitter) have been developed for data transfer between serial I/O device and the microcomputer in the form of the chips. The USART is most powerful and commonly used LSI chip. It provides a programmable serial communication interface between the microprocessor and serial I/O devices. The data transfer between the microprocessor and USART takes place in the parallel form. On the other hand the data transfer between the I/O devices and the USART is in the serial form. The USART has to be initialized before the data transfer takes place. The desired data format and synchronization method for the data transfer are specified during initialization by command byte written by the microprocessor for the USART. Thus an USART works as parallel to serial converter from microprocessor to I/O devices and vice-versa. Here we shall discuss the details of the popular USART chip 8251.

14.6 BLOCK DIAGRAM OF 8251A

The 8251A is a programmable communication interface available in the form of IC dual in line package. It consists of 28 pins and requires + 5 V d.c. supply for its operation. Figure 14.10 shows the pin diagram of 8251A. The pin details are as given below:

D_0-D_7	Data bus (8 bits)	$\overline{RxC}$	Receiver Clock
C/$\overline{D}$	Control or data to be written or read	RxD RxRDY	Receiver Data Receiver Ready
$\overline{RD}$	Read Data	TxRDY	Transmitter Ready
	Command	$\overline{DSR}$	Data Set Ready
$\overline{WR}$	Write Data or Control Command	$\overline{DTR}$ SYNDET/BD	Data Terminal Ready Sync/Break Detect
CLK	Clock Pulse (TTL)	$\overline{RTS}$	Request to Send Data
$\overline{CS}$	Chip Enable	$\overline{CTS}$	Clear to Send Data
RESET	RESET Input	TxE	Transmitter Empty
$\overline{TxC}$	Transmitter Clock	V_{CC}	+ 5 V
TxD	Transmitter Data	GND	Ground

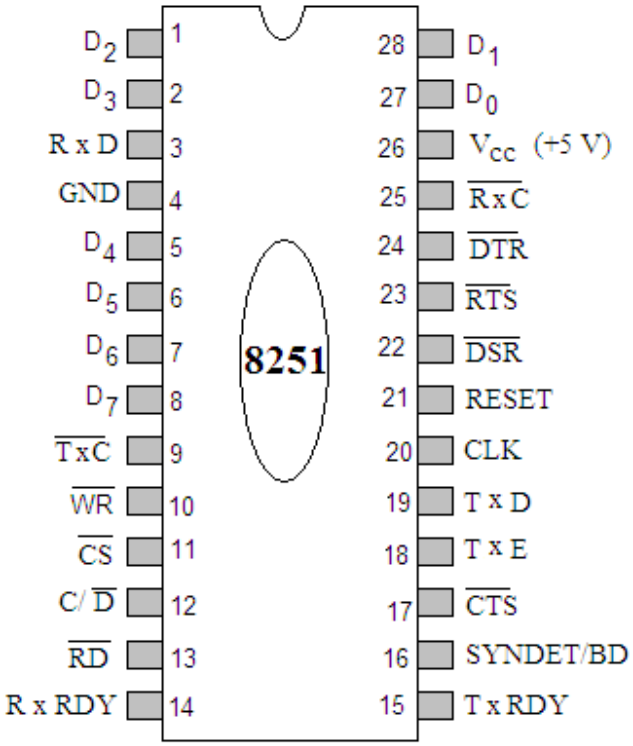

Fig. 14.10

The functional block diagram of 8251A is shown in figure 14.11. It includes the following four sections:

- **Read/Write Control Logic**
- **Transmitter Section**
- **Receiver Section**
- **Modem Control**

14.6.1 Read/Write Control Logic

This section includes 6-input signals: $\overline{CS}$, $C/\overline{D}$, $\overline{WR}$, *RESET* and *CLK*; and three buffer registers:

- **Control Register**
- **Status Register**
- **Data Bus Buffer Register**

$\overline{CS}$: It is a Chip Select terminal. A low to this terminal selects the 8251A for communication with the microprocessor. This is connected to a decoded address bus.

$C/\overline{D}$: It is a Control/Data pin. A high on this terminal addresses the control register or status register; whereas a low addresses the data bus buffer.

$\overline{WR}$: It is an active low Write signal. When a low signal is applied to this terminal, the microprocessor either writes in the control word register or

sends output to the data buffer. This pin is connected to either $\overline{IOW}$ or $\overline{MRMW}$.

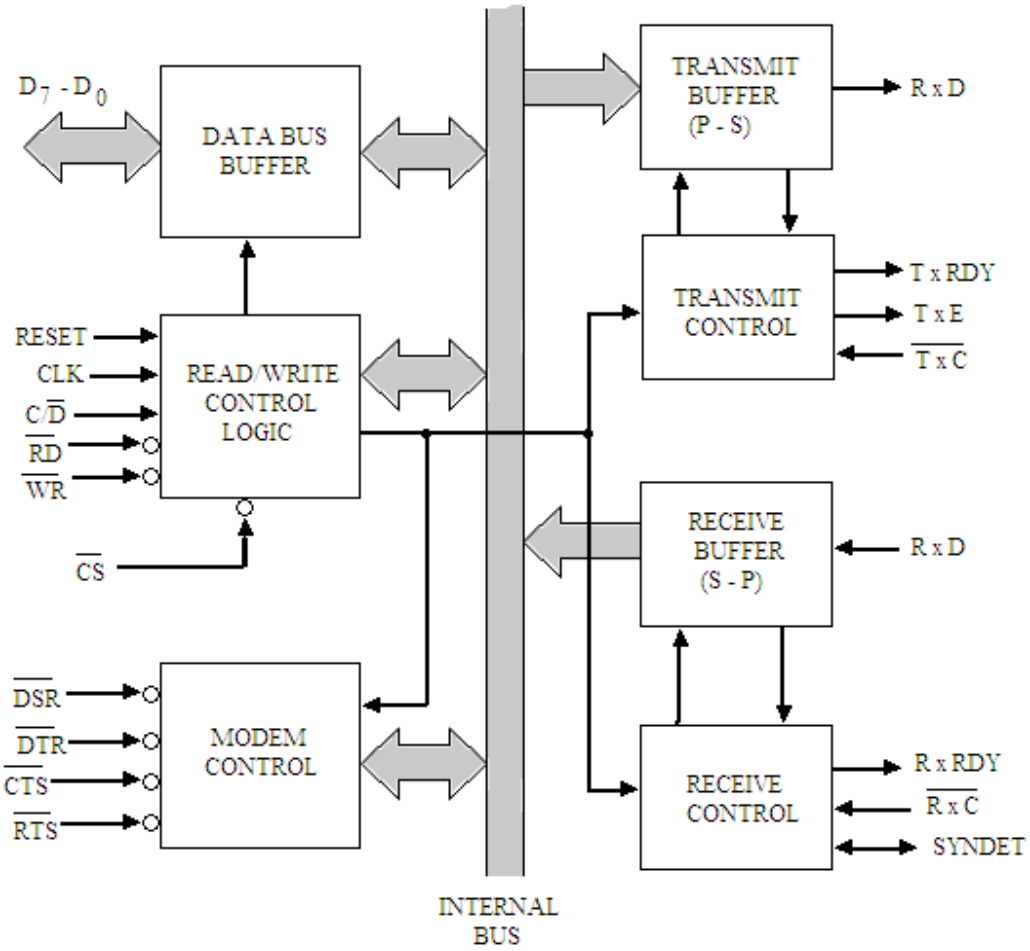

Fig. 14.11

$\overline{RD}$: It is an active low Read signal. When this terminal is low, the microprocessor either reads the status from the status register or accepts data from the data buffer. This is connected to either $\overline{IOR}$ or $\overline{MEMR}$.

RESET : It is a Reset input pin. When this terminal is high, it resets the 8251 and forces it in the idle mode.

CLK : This is the Clock input, usually connected with the system clock.

The details of the three registers are as:

Control Register:

This is a 16-bit register and contains the control word with two independent bytes.

The first byte is called the Mode Instruction Word, and

the second byte is called the Command Instruction Word.

This register can be accessed as an output port when $C / \overline{D}$ pin is high.

Status Register:

This input register checks the Ready status of a peripheral. This register is addressed as an input port when $C/\overline{D}$ terminal is high. It has the same port address as the control register.

Data Bus Buffer Register

This is a bidirectional register and can be addressed as an input port and an output port when $C/\overline{D}$ pin is low. Table 14.2 gives the summary of interfacing and control signals.

Table 14.2

$\overline{CS}$	$C/\overline{D}$	$\overline{RD}$	$\overline{WR}$	Functions
0	1	1	0	Microprocessor writes instruction in USART control register.
0	1	0	1	Microprocessor reads from USART status register.
0	0	0	1	Microprocessor outputs data to USART data buffer.
0	0	0	1	Microprocessor accepts data from USART data buffer.
1	X	X	X	USART not selected.

Figure 14.12 shows the expanded version of this section.

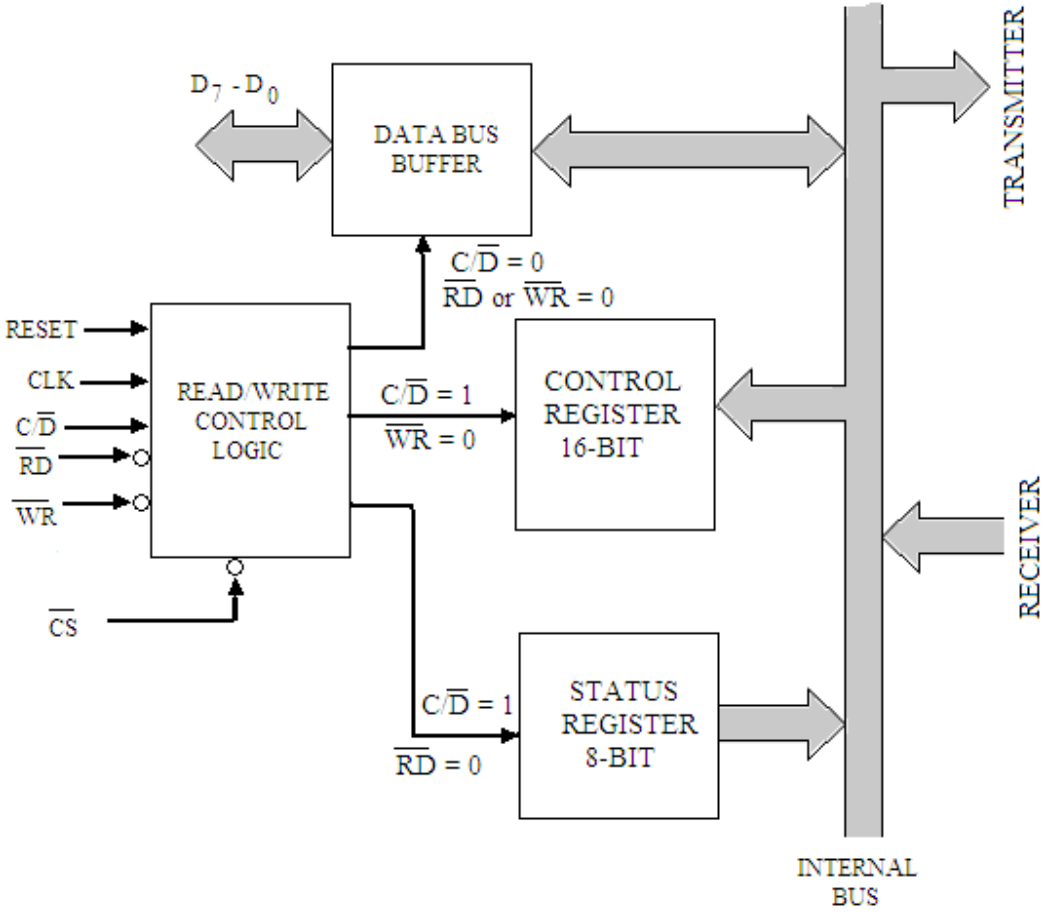

Fig. 14.12

14.6.2 Transmitter Section

The expanded block diagram of the transmitter section is shown in figure 14.13. It consists of the following registers:

- Transmitter Buffer Register – It holds 8-bit data.
- Serial Output Register – Converts 8-bits into a stream of serial bits.
- Transmitter Control Logic – It directs the output register to send the serial data at the output register through TxD terminal.

Three output signals and one input signal are also associated with the transmitter section. These signals are describes as:

TxD : It is **Transmit Data** terminal. The serial bits are transmitted on this line.

$\overline{TxC}$: This pin is **Transmitter Clock**. This controls the rate at which bits are to be transmitted by the 8251A. The clock frequency can be 1, 16 or 64 times of the baud.

TxRDY : This is **Transmitter Ready** pin. When this output terminal is high, it indicates that the buffer is empty and the 8251 is ready to accept a byte. It can be used either to interrupt the microprocessor or to indicate the status. This signal becomes reset when the data byte is loaded into the transmitter buffer register.

TxE : This is **Transmitter Empty** signal used as output terminal. A high on this terminal indicates that the output register is empty and becomes reset when a byte is transferred from the buffer register to the output register.

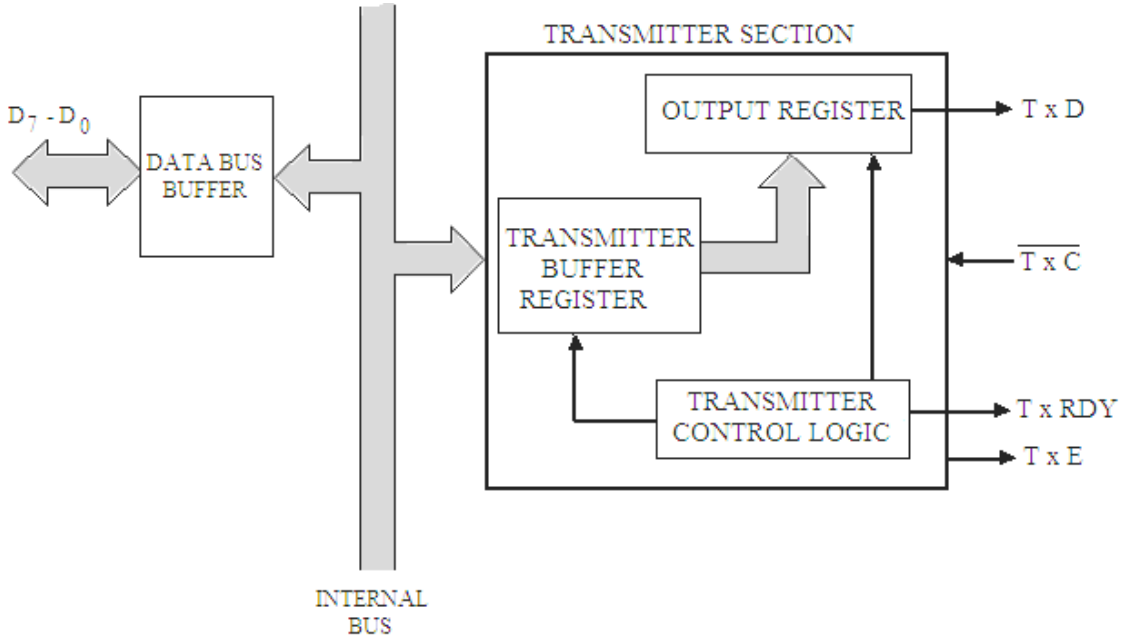

Fig. 14.13

14.6.3 Receiver Section

The expanded block diagram of the receiver section is shown in figure 14.14. It consists of the following registers:

- Receiver Buffer Register
- Serial Input Register
- Receiver Control Logic

The receiver section accepts serial data on the RxD terminal and converts it to parallel data. When the RxD line goes low, the control logic assumes that it is a START bit and waits for half a bit time, and samples the line again. It the line is still low, the input register accepts the next coming bits and forms a character. The character is then loaded to the buffer register. Subsequently, the parallel byte is transferred to the microprocessor when a request is made. Following signals are associated with the receiver section which are described below:

RxD : It is **Receive Data** terminal. The serial bits are received on this line and converted to a parallel byte in the receiver input register.

$\overline{RxC}$: This pin is **Receiver Clock**. This controls the rate at which bits are received by the 8251A. In the asynchronous mode, the clock can be set to 1, 16 or 64 times of the baud.

RxRDY : This is **Receiver Ready** pin. When this output terminal is high, the 8251A has a character in the buffer register and is ready to transfer it to the microprocessor. It can be used either to indicate the status or to interrupt the microprocessor.

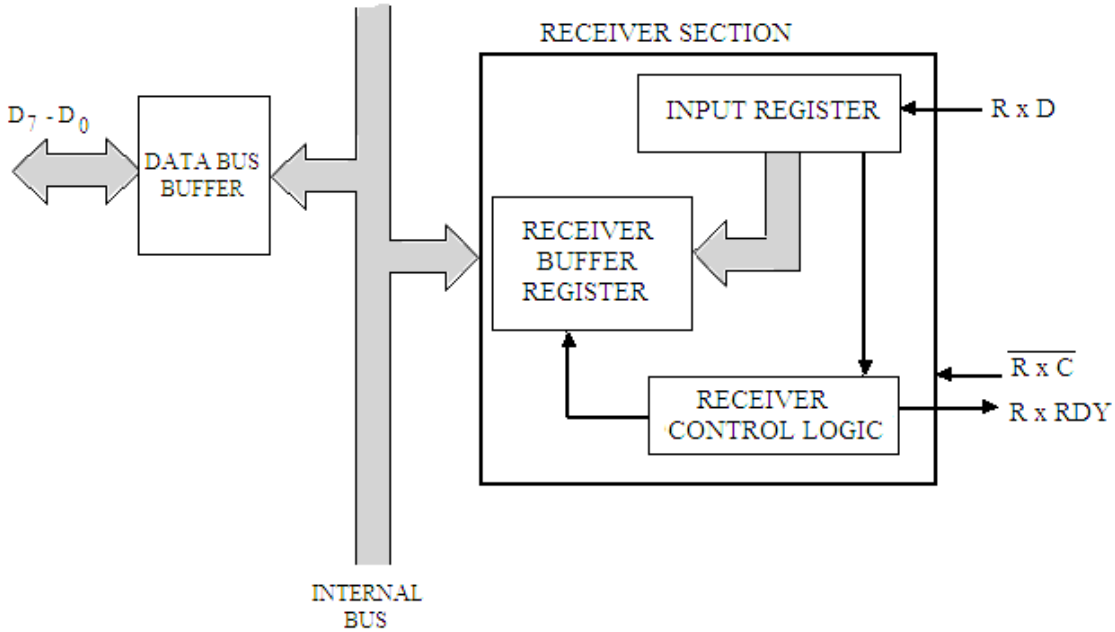

Fig. 14.14

14.6.4 Modem Control

The modem control section of the 8251A provides two input signals $\overline{DSR}$ (Data Set Ready) and $\overline{CTS}$ (Clear to Send); and two output control signals *DTR* (Data Terminal Ready) and *RTS* (Request to Send) to handle DTE and DCE. These signals are described as:

$\overline{\text{DSR}}$ (Data Set Ready): This is an active low input terminal used by the modem to indicate that it is ready for communication.

$\overline{\text{CTS}}$ (Clear to Send): This active low input terminal is used by the modem to signal the DTE that the communication channel is clear and it can send out the serial data.

DTR (Data Terminal Ready): This output signal is used by the 8251 to signal the modem to indicate that the terminal is ready to communicate.

RTS (Request to Send): This output signal is used by the 8251A to signal to modem that it has data to be transmitted.

14.7 INTERFACING OF 8251A

Figure 14.15 shows the interfacing connection of 8251A with the microprocessor. The eight data lines of 8251A are to be connected to the data bus of the microprocessor.

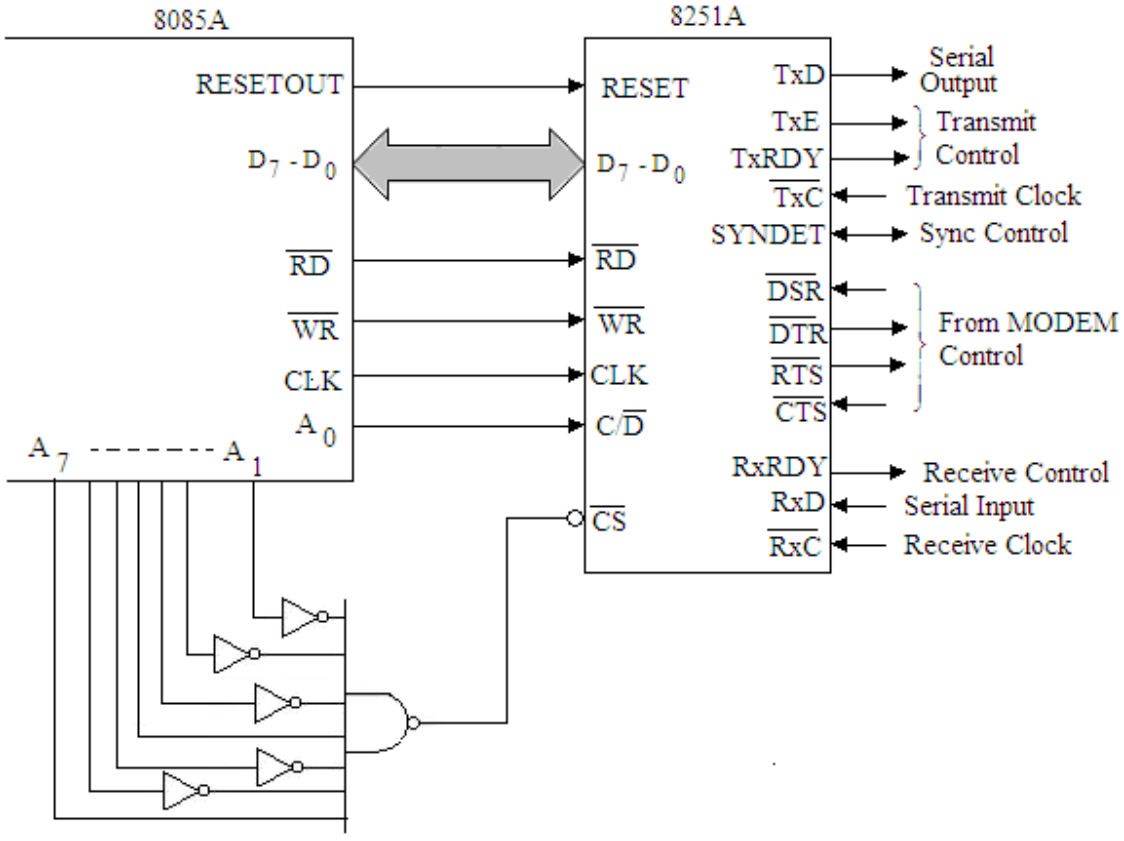

Fig. 14.15

The $\overline{RD}$ and $\overline{WR}$ lines of 8251A are to be connected to the $\overline{RD}$ and $\overline{WR}$ of the control lines of 8085A microprocessor respectively. The CLK pin of the 8251A is be connected to the CLK out terminal of the microprocessor. The RESET pin is connected to the RESETOUT of the microprocessor. The terminal $C/\overline{D}$ is used to select the internal registers either control register or data register. So it is connected to the A_0 address line of the microprocessor. The chip select terminal $\overline{CS}$ of the PCI 8251A is to be connected to the output of an address decoder circuit. The address decoder circuit uses the address lines A_1 to A_7 of the microprocessor. From the decoder circuit used in this figure, the chip select terminal of 8251A will be enabled when A_7 and A_4 are high and all other inputs are low. The port addresses for reading the data word, writing the data word, reading the status word and writing the control word will be as shown in table 14.3.

Table 14.3

A_0	$\overline{RD}$	$\overline{WR}$	Function	Port Address
0	0	1	Read Data Word	90 H
0	1	0	Write Data Word	90 H
1	0	1	Read Status Word	91 H
1	1	0	Write Control Word	91 H

14.8 PROGRAMMING OF 8251A

It has already been discussed that there is a 16 bit control register in a 8251A which contains two independent bytes (words). The first byte (word) is known as mode word which tells about the initialization parameters like mode (Asynchronous or Synchronous), baud, stop bits and parity bits etc. The second byte (word) is known as command word which tells about enabling the transmitter and receiver sections. The readiness of the peripherals can also be checked by reading the status word.

14.8.1 Initialization of 8251A in Asynchronous Mode

To initialize 8251A in asynchronous mode, a certain sequence of control words must be followed. After a reset operation (through system RESET or through instruction) a mode word must be written into the control register followed by a command word. Any control word written into the control register immediately after the mode word will be interpreted as a command word that means a command word can be changed anytime during the operation. However, the 8251A should be reset prior to writing a new mode word, and it can be reset using internal reset bit (D_6) in the command word.

Figure 14.16 shows the format of the mode word. The bits of this mode word are described below:

Bits D_1-D_0: These bits program the baud rate factor. These bits are set to 00 for synchronous operation. However, for asynchronous operation these bits specify the factor by which the transmit/receive clocks $\overline{TxC}$ and $\overline{RxC}$, exceeds the baud rate. The other clock inputs CLK to the 8251A is used to generate the internal device timing and must simply be greater than 30 times the transmitter/receiver baud rate.

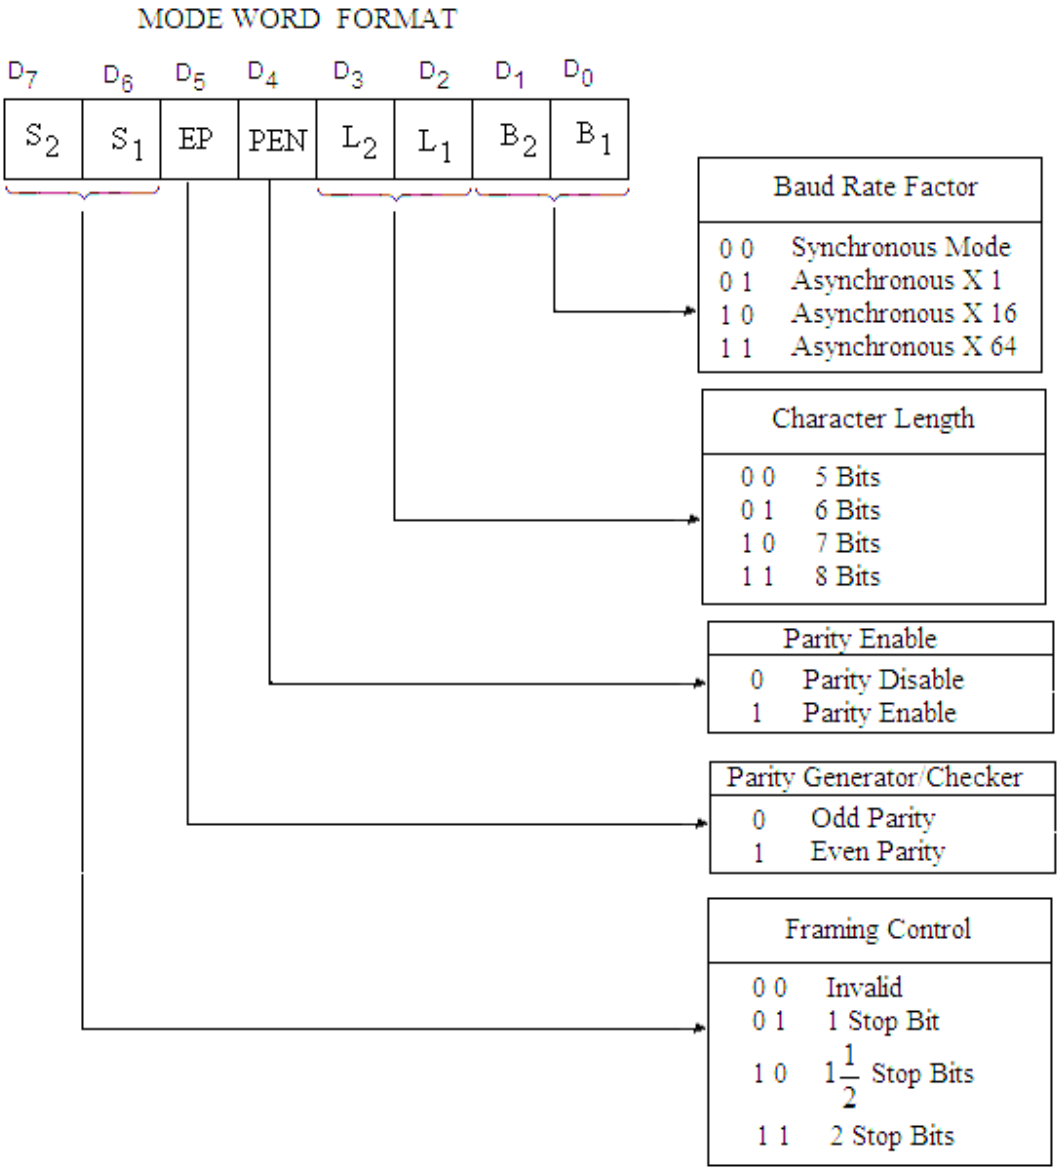

Fig. 14.16

Bits D_3-D_2: These bits specify the number of data bits in the character is to be sent or received.

Bit D_4: This bit enables the parity. If this bit is 0, the parity is disabled.

Bit D_5: This bit selects the even or odd parity. If this bit is 0, odd parity is selected. The even parity is selected if this bit is 1.

Bit D_6-D_7: These bits specify the number of stop bits.

Command Word

Once the function definition of the 8251A has been programmed by the mode word instruction, the device is ready for data communication. The command word

instruction controls the actual operation of the selected format. Functions such as Enable Transmit/ Receive, Error Reset and modem control are provided by the command word instruction. The format of the command word is shown in figure 14.17.

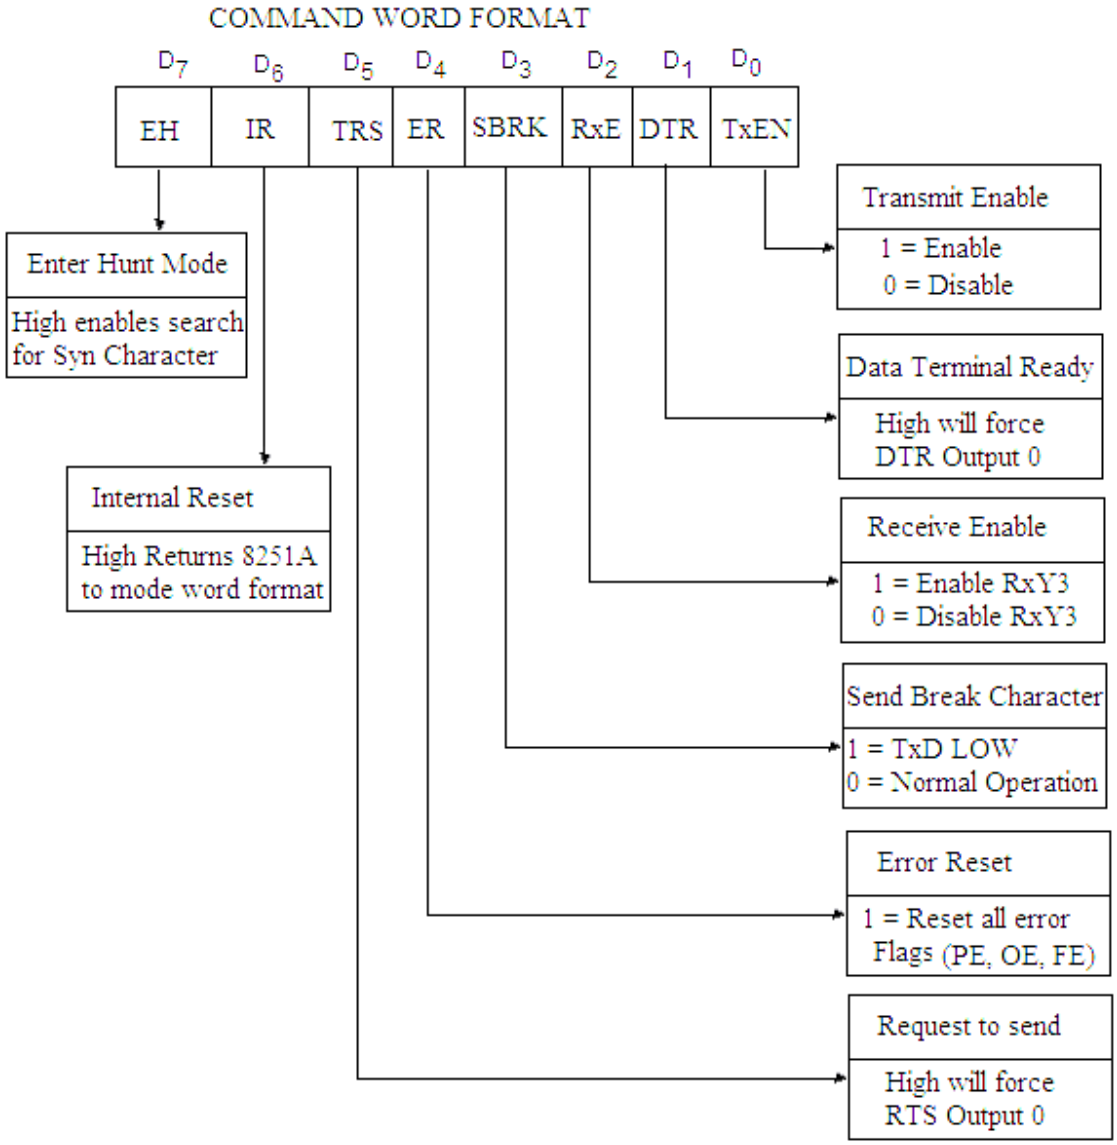

Fig. 14.17

The bits of the command word are described below:

Bit D_0: This bit enables the Transmitter.

Bit D_1: This bit controls the Data Terminal Ready.

Bit D_2: This bit enables the Receiver.

Bit D_3: This bit makes the transmitter to send continuous break characters.

Bit D_4: This resets the error flags. It resets Parity Error flag (PE), Over Run Error flag (OE) and Framing Error flag (FE).

Bit D_5: This bit controls the request to send to RTS pin of the device. A high at this bit makes the RTS pin to become active.

Bit D_6: It is used as an internal reset. A high to this bit resets the device, so that a new mode word can be entered.

Bit D_7: It is used in synchronous mode. It enables the receiver to look for the synchronous data.

Programming Sequence

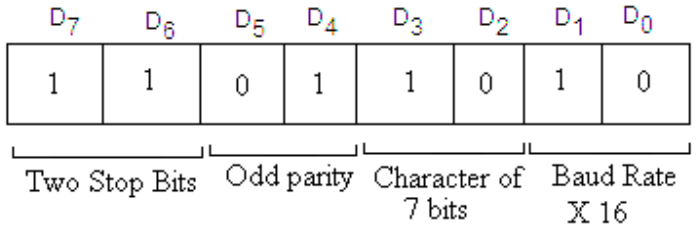
When programming the 8251A in asynchronous mode, following sequence must be followed:

1. Reset (either internal or external)
2. Mode Instruction (specify the asynchronous mode)
3. Command Instruction

The resetting of the 8251A can be done by loading the control register with a command word whose D_6 bit is high. This bit reset the device. The command word is, therefore, loaded as:

```
MVI A, 40 H     ; Command word whose D6 bit is high is loaded to accumulator.
OUT 91 H        ; Command word is loaded to control register whose port address is 91 H as discussed earlier.
```

Now the mode instruction word is loaded to the control register. The mode word is formed as per the required modes of transmission. For example, for asynchronous transmission with 7 data bits, 2 stop bit and odd parity; also a 16 X clock is used. For this the format is shown in figure 14.18 and mode word will be given as:



$= DA\ H$

Fig. 14.18

```
MVI A, DA H     ; Mode word is loaded to accumulator.
OUT 91 H        ; Mode word is loaded into control register.
```

The command word with RTS, error reset and DTR enable with be given as shown in figure 14.19.

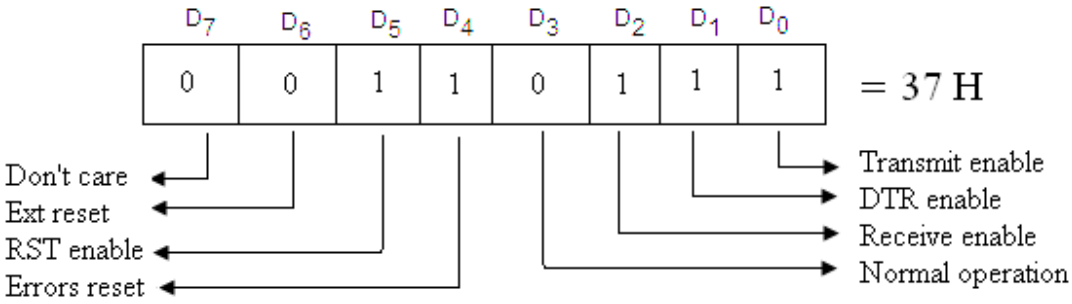


Fig. 14.19

The command word to be loaded in the control register is given below:

```
MVI A, 37 H          ; Command word is loaded to accumulator.
OUT 91 H             ; Command word is loaded into control
                       register.
```

For initializing the 8251A a dummy mode is sent before resetting it. The resetting is done using command word with D_6 bit as 1. The mode word followed by the command word is sent. With all these requirements the initialization program of 8251A is writhen as:

```
MVI A, 00 H
OUT 91 H             ; Dummy mode word.
MVIA, 40 H           ; Resetting of 8251A by using the command
                       word with D6 bit as high.
OUT 91 H
MVI A, DA H          ; Mode word is loaded to accumulator.
OUT 91 H             ; Mode word is loaded into control register.
MVI A, 37 H          ; Command word is loaded to accumulator.
OUT 91 H             ; Command word is loaded into control
                       register.
```

14.8.2 Initialization of 8251A in Synchronous Mode

When programming the 8251A in asynchronous mode, following sequence must be followed:

1. Reset (either internal or external)
2. Mode Instruction (specify the Synchronous Mode and number of synchronizing characters)

3. One or two synchronizing character
4. Command Instruction

For initializing of the 8251A in synchronous mode the mode instruction word is to be written only after resetting the PCI as in the case of asynchronous mode. Then with one or two sync characters, a command word is written in the control register. The mode word format in synchronous operation is shown in figure 14.20. As discussed earlier the D_1 and D_0 bits program the baud rate factor which are set 00 for synchronous operation.

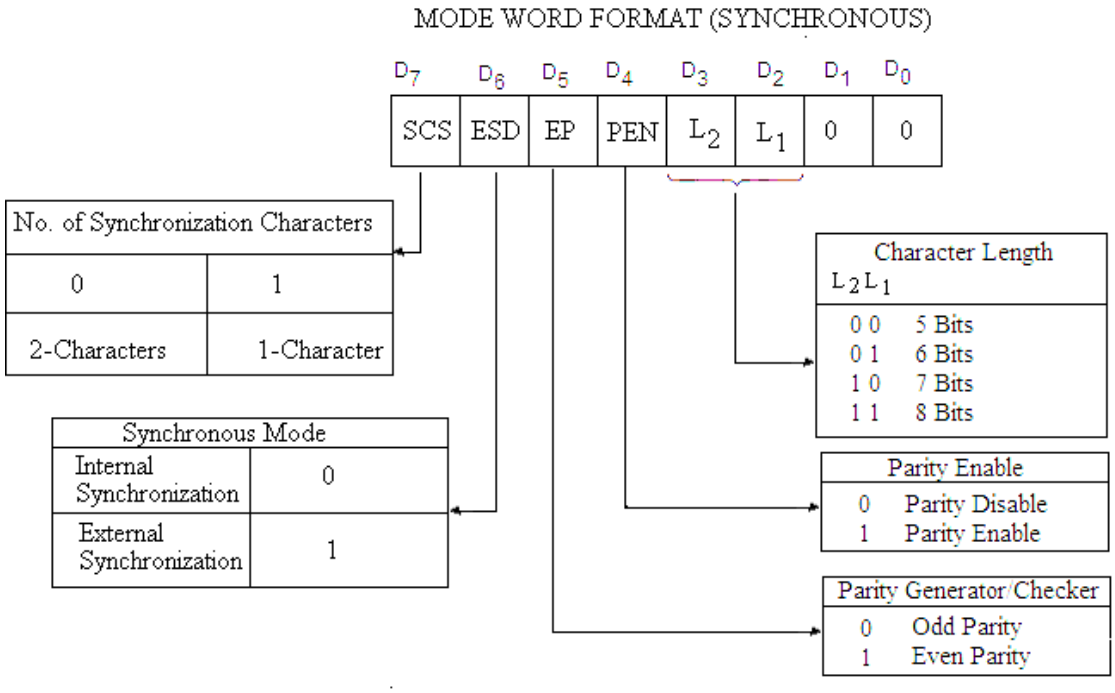

Fig. 14.20

The format to be used for command instruction format for the synchronous operation is the same as for the asynchronous operation which is shown in figure 14.21. Once the functional definition of the 8251A has been programmed by the mode instruction and the Sync characters are loaded (in synchronous mode) then the device is ready to be used for data communication. The command instruction controls the actual operation of the selected format. Functions such as Enable Transmit/ Receive, Error Reset etc are provided by the command instruction.

Once the mode instruction has been written into the 8251A and Sync characters inserted, then all further "control writes" ($C / \overline{D} = 1$) will load a command instruction. A reset operation (internal or external) will return the 8251A to the mode instruction format.

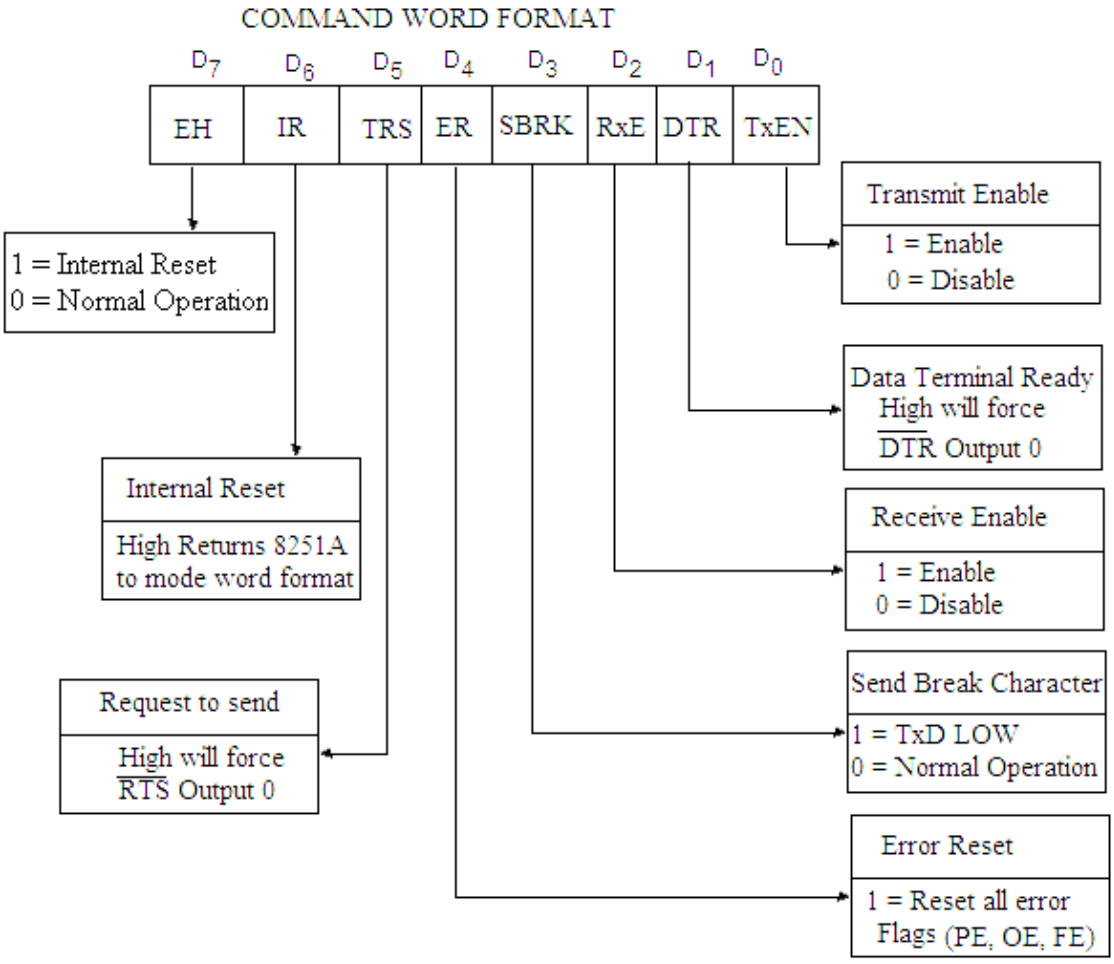

Fig. 14.21

In data communication system, it is necessary to examine the status of the active device to ascertain if errors have occurred or other conditions that require the processor's attention. The 8251A has facilities that allow the programmer to read the status of device at any time during functional operation. A normal read command is issued by the CPU with $C/\overline{D}=1$ to accomplish the function.

The microprocessor can output the data to be transmitted only after checking the status TxRDY (D_0) bit of status word as shown in figure 14.22. The sync characters will automatically be inserted if the buffer of the transmitter becomes empty at any time.

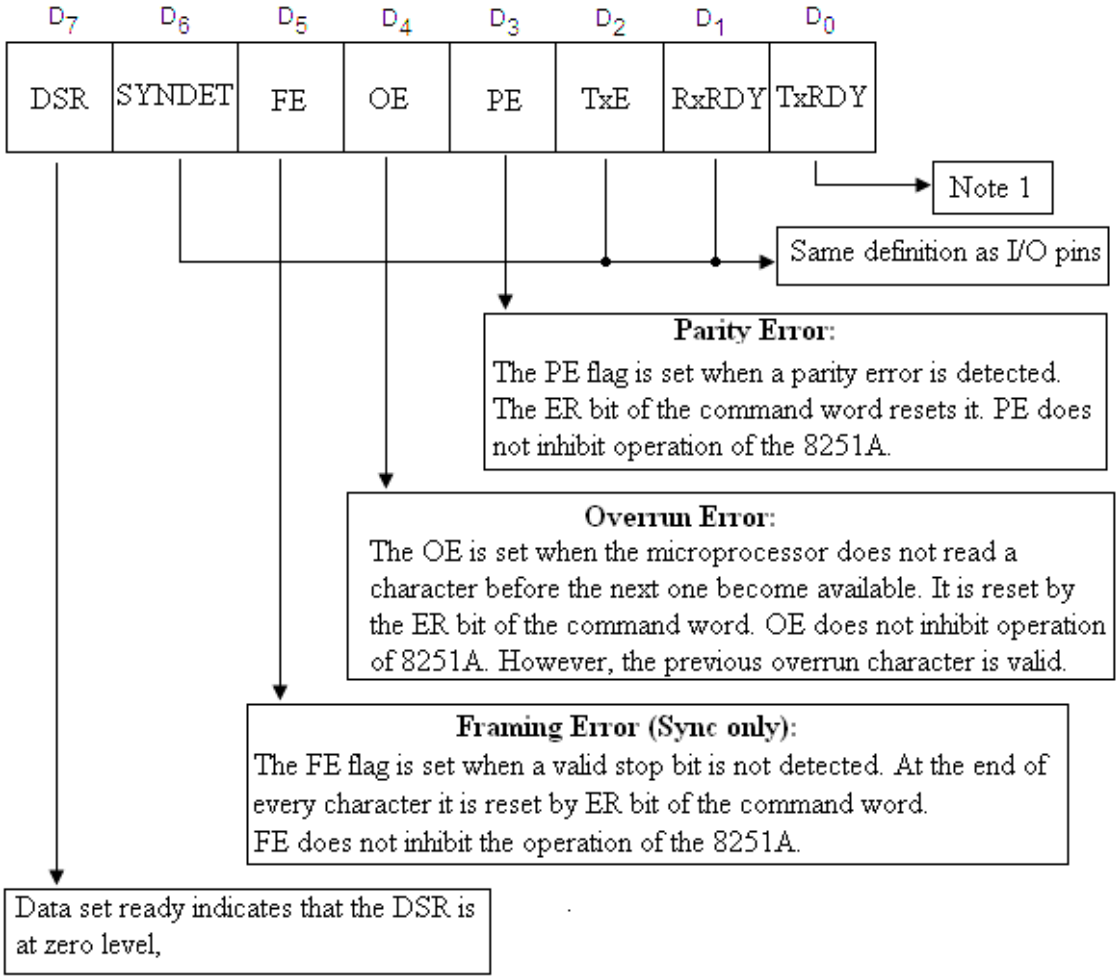

Fig. 14.22

Example 14.1 *Write a subroutine program to transmit serially 256 bytes of data stored in the memory locations starting at 3000 H. The bytes are to be transmitted in synchronous mode (without parity) with two sync characters using 8251A. Consider 90 H and 91 H are the port addresses for control/status register and data register respectively.*

Solution. The mode word format for the given problem is shown in figure 14.23.

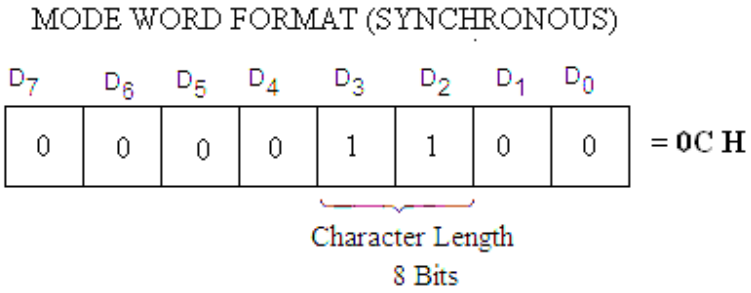

Fig. 14.23

The subroutine program may then be given as:

SUBROUTINE PROGRAM

Label	**Mnemonics**	**Operand**	**Comments**
	LXI H,	3000 H	; Initialize H-L register pair for index pointer.
	MVI C,	FF H	; Register C to be used as counter.
	MVI A,	00 H	; Dummy word
	OUT	91 H	
	MVI A,	40 H	; Command word for resetting 8251A.
	OUT	91 H	; Command word loaded to the control register.
	MVI A,	0C H	; Mode word 0C H is loaded to the accumulator.
	OUT	91 H	; The mode word for two sync character is loaded to the control register.
STATUS	IN	90 H	; Read the status word.
	ANI	01 H	; Mask all the bits except D_0 for checking the status.
	JZ	STATUS	; If D_0 bit is zero jump to STATUS to read again.
	MOV A,	M	; Loads the character to be transmitted to the accumulator.
	OUT	91 H	; Character is transmitted.
	DCR	C	; Decrements the data in C register for next byte for transmission.
	JNZ	STATUS	; If all bytes are not transmitted then jump to STATUS to read the next byte.
	RET		; Returns to main program.

PROBLEMS

1. What are the advantages and disadvantages of serial I/O data transfer over the parallel I/O data transfer?
2. Name three methods of serial mode of data transfer and explain them in brief.
3. Draw and explain the block diagram of Programmable Communication Interface 8251A.
4. Discuss the Transmission section of 8251A.
5. Discuss the Receiver section of 8251A.
6. Explain the working principle of RS 232 interface.
7. Explain how Programmable Communication Interface 8251A is interface with the CPU.
8. Draw the schematic diagram of interfacing 8251A with 8085 microprocessor. The connections should be such that the port address for control register and data registers are 71 H and 70 H respectively.
9. Explain the mode word format of 8251A.
10. Explain the command word format of 8251A.
11. Explain how the 8251A is initialized in Asynchronous mode.
12. Explain hoe the 8251A is initialized in synchronous mode.
13. Explain the following terms related to 8251A:
    $C/\overline{D}$, $\overline{RxC}$, RxD, $\overline{DSR}$, $\overline{TxC}$, TxD, $\overline{DTR}$, $\overline{CTS}$
14. Explain the following terms related to 8251A:
    $RxRDY$, $TxRDY$, $TxEMPTY$

15

Applications of Microprocessor

After the study of all the details of microprocessor 8085, including the assembly language programming and peripheral devices we are now in a position to design some microprocessor based systems. Real time clock with on/off timer, running light, washing machine control, water level control etc. are some designs will be discussed in this chapter. These designs are supposed to be very interesting and useful. The assembly language programming of these designs have been verified on M/S Vinytics Kit

15.1 REAL TIME CLOCK WITH ON/OFF TIMER

In the present section of this chapter, the details of the assembly language programming of the design of Real Time Clock with On/Off Timer will be discussed. In this microprocessor based design six FNDs of the microprocessor kit (four of address field and two of data field) have been used to display the current time. The four 7-segments of the address field would display hours and minutes of the current time and two 7- segments of data field would display the seconds of the current time. For example, current time is 10:25:30, the address and data field of the kit would display as shown in Fig. 15.1. It would then continuously update the current time after every second. In other words, it will work as the real time clock (digital clock).

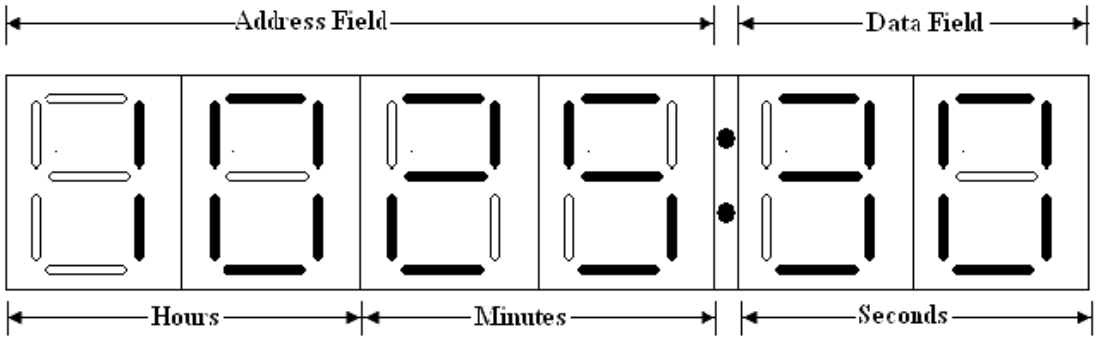

Fig. 15.1

For the working of real time clock, the software prepared was checked on the Vinytics kit (VMC-8506) and found to work satisfactorily. Two monitor programs (stored in Kit's ROM /EPROM) at the locations 0347 H (for clearing the display) and 05D0 H (displaying the contents of memory of memory locations 2050 H through 2055 H in the address and data fields respectively) have been used in the program. Please note that before calling the display routine, registers A and B are required to be initialized with either 00 or 01 to indicate to the monitor program as to where the contents of above mentioned memory locations are to be displayed (e.g. address field or data field) and whether a dot is to be displayed at the end of address field or not. The assembly language program was executed to switch ON an electrical appliance after a preset time period. This program was proved to be very useful microprocessor based system. This type of microprocessor based system has the useful requirement in research laboratories. An electronic circuit was also designed which was interfaced with the 8085A microprocessor through the programmable peripheral Interface (PPI) 8255A. The PPI-8255A was available with the microprocessor kit.

ASSEMBLY LANGUAGE PROGRAM

The assembly language program for the universal timer and for switching ON electrical device is given below:

PROGRAM

Main Program

Label	Mnemonics	Operand	Comments
	LXI SP,	27FF H	;Initialize Stack Pointer.
	MVI A,	80H	;Control word for 8255-I.
	OUT	03H	;Work all the ports of 8255-I as output port .
	CALL	0347 H	;Clears the display. It is the program stored in ROM of the kit.
AA	XRA	A	;Clears the accumulator
	MOV B,	A	;Clears the B register also.

```
        LXI H,      2050 H      ;Intialize H-L pair where the
                                 current time is stored.
        CALL        05D0 H      ;Displays the current time in
                                 address field. It is the
                                 program stored in ROM of
                                 the Kit.
        MVI A,      01 H        ;Stores 01 H in accumulator.
        MVI B,      00 H        ;Stores 00 H in B register.
        LXI H,      2054 H      ;Initialize H-L register pair
                                 with 2054 H.

        CALL        05D0 H      :Displays the current time in
                                 data field.
        CALL        ONOFF       ;Calls subroutine program to
                                 switch on the electrical
                                 appliance.
        LXI H,      2055 H      ;Initialize H-L register pair
                                 with 2055 H.
        MOV A,      M           ;Moves the least significant
                                 digit (LSD) of current
                                 seconds to the accumulator.
        ADI         01 H        ;Add 01 to the accumulator.
        CPI         0A H        ;Compares with 0A H.
        JZ          RR          ;If Acc.=0A H, then jump to
                                 RR, indicating that LSD of
                                 seconds has become 9. Else
                                 goes to next statement.
        MOV M,      A           ;Moves the accumulator
                                 contents to memory
                                 location addressed by H-L
                                 register pair i.e. current
                                 seconds are stored back in
                                 the memory locations.
DD      MVI B,      02 H        ;Stores 02 H in accumulator.
YY      LXI D,      FA00 H      ;Intialize D-E register pair
                                 with FA00H.
        CALL        DELAY       ;Calls the delay program.
        DCR         B           ;Decrement B- register.
        JNZ         YY          ;If B≠0 then jump to YY.
        JMP         AA          ;Jump to AA for the display
                                 of current time.

DATA

2050 H	-	MSD of hrs.	Current Time
2051 H	-	LSD of hrs.	
2052 H	-	MSD of Minutes	
2053 H	-	LSD of Minutes	
2054 H	-	MSD of Seconds	
2055 H	-	LSD of Seconds	

2056 H	-	01H (if wish to switch ON the electrical appliance)	
2057 H	-	MSD of Hrs.	
2058 H	-	LSD of Hrs.	
2059 H	-	MSD of Minutes	
205A H	-	LSD of Minutes	Time For On Electrical
205B H	-	MSD of Seconds	Appliance
205C H	-	LSD pf Seconds	

This program written in assembly language is self-explanatory. The comment column will help in understanding the operation of the project. The current time is stored in the beginning before the start of the program in the memory locations starting at 2050 H to 2055 H. In the memory location 2056 H, 01H is stored if we wish to switch on the electrical device connected with the PPI-8255 A; otherwise any number can be stored in this memory location. If 01H is stored in the memory location 2056H, then the time for switching ON the electrical appliance is stored in the memory location starting at 2057 H to 205C H. Suppose current time, when we wish to start the program is:

Hrs.	Min.	Sec.
02	25	30

And we wish to switch on the electrical appliance at:

Hrs.	Min.	Sec.
04	23	00

The data to be stored in the memory locations starting at 2050 to 205C is given below:

Memory Location	**Data**		
2050 H	00 H	02 Hrs.	
2051 H	02 H		
2052 H	02 H	25 Minutes	Current Time
2053 H	05 H		
2054 H	03 H	30 Seconds	
2055 H	00 H		
2056 H	01 H	01 for switch ON the appliance	
2057 H	00 H	04 Hrs.	
2058 H	04 H		Time when
2059 H	02 H	23 Minutes	electrical
205A H	03 H		appliance to
205B H	00 H	00 Seconds	ON
205C H	00 H		

A relay circuit to be connected to the Programmable Peripheral Interface IC 8255-I is shown in Fig. 15.2.

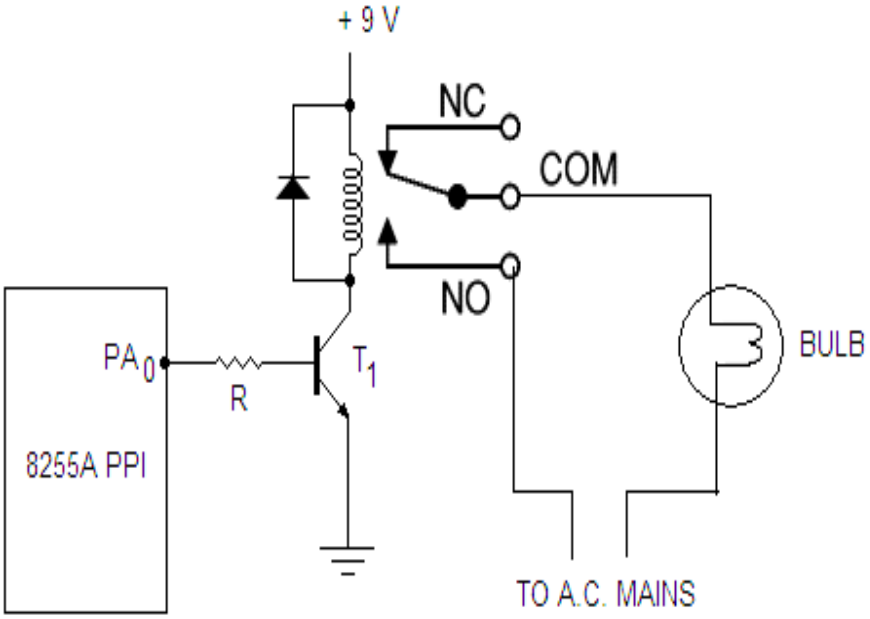

Fig.15.2

This circuit consists of a relay, a diode and transistor. The base of the transistor is connected to PA_0 of 8255 although a 10 k resistance. A diode IN4007 is connected in parallel with coil of 12V relay. The electrical appliance is connected to the a.c.mains through the N/O pins of the relay.

The working of this circuit may be explained as:

When a high signal is available through the software to a PA_0 (D_0 bit of port A) of 8255-I, the transistor goes into saturation. The relay is energized. The N/O terminals of the relay get connected and electrical appliance become ON.

When the program is executed, the current time is displayed in the address and data fields of the microprocessor kit. The current time is updated after every second by the programming. For this LSD (Least significant Digit) of the seconds is transferred to accumulator, which is added with 1. The contents after addition are compared with 0A H (decimal number 10). In other words LSD of the second is continuously increased (after every one second) by 1 to reach to 0A H. When it reaches to 0A H then program will jump to MSD (Most Significant Digit) of the seconds after storing 00H in the memory location 2050 H.

Now MSD of the second is moved into accumulator and then increased by 1 which then compared with 06H.

When MSD of the second reaches to 06H, it will make 00H to its corresponding location. The program will then jump to LSD of the minutes. The program will execute in such a way the minutes will be checked after every one minute and it will be updated in the address field so that it displays up to 59H. After that, it becomes 00 H.

In the similar fashion, Hrs. will be checked after every hour so that it displays the updated current time.

To switch ON the electrical appliance at the predetermined time the subroutine program was developed. The subroutine program is executed after every second to check if the current time is equal to the time when the electrical appliance is to switched ON. When the current time is equal to the ON time (required time), 8255A sends a high signal to PA_0 (D_0 bit of Port A). The high signal energies the relay and appliance becomes ON. After switching ON the appliance the program will, however, continue displaying the updated time.

The observations were made to check the ON time and found to work fine. The working of the real time clock was also very accurate. It was proved to be satisfactory assembly language programming of the 8085A.

Further, to change the real time clock to display the timing in address and data field in 24 Hrs., i.e. after 12:59:59 it should display 13:00:00 onwards, rather than 01:00:00 onwards. So certain changes in the main program should be incorporated. The instructions marked by stars (*****, ******, *******) be replaced as given below:

***** Replace the instruction CPI 03 H by CPI 05 H

****** Replace the instruction CPI 01 H by CPI 02 H

******* Replace the instruction MVI A, 01 H by MVI A, 00 H.

15.2 MICROPROCESSOR BASED LED DIAL CLOCK

Here the design of microprocessor based LED dial clock has been discussed which runs using microprocessor 8085. It works purely on the basis of the software; and some hardware has also been used. The software is prepared in the assembly language of 8085A microprocessor. This program was tested on Vinytics 8085 µp kit and found to work very fine.

In this dial clock 73 LEDs are used which are interfaced with the different ports of two 8255 PPI ICs available on µp kit. Out of 73 LEDs, 12 LEDs of Amber color are used to show hours, 60 LEDs of red color are used to show minutes and one green LED alternately glows for half second showing that the seconds are continuously being counted by the clock. All these LEDs are connected in a circle in the form of a dial of a wall clock. The beauty of this project is the software part; and the students of Electronics discipline would definitely like to design this project or this idea may be used in other

projects also. It is worthwhile to mention that no electronic circuit was used, except the LEDs are connected to the two PPI-8255 ICs available with the microprocessor kit.

Figures 15.3 and 15.4 show the circuit diagrams to be interfaced with the μp-Kit. The cathodes of all the 12 Amber colored Hours LEDs are connected to the ground. The Anodes of these LEDs are connected to the Port A and Port B of 8255 –II, the anodes of LEDs showing Hrs 1 to 8 are connected respectively to D0 –D7 Bits of Port A of 8255-II and the anodes of LEDs showing Hours 9 to 12 are connected respectively to D0 – D3 bits of Port B of 8255 – II. Look – up table 15.1 provides Logic 1 to Hours LEDs 1-8. However, logic 1 to Hours LEDs 9 – 12 are provided using the software. The bit D0 of Port C lower of 8255 – II is connected to the anode of Green LED (showing second) and cathode of this LED is also grounded.

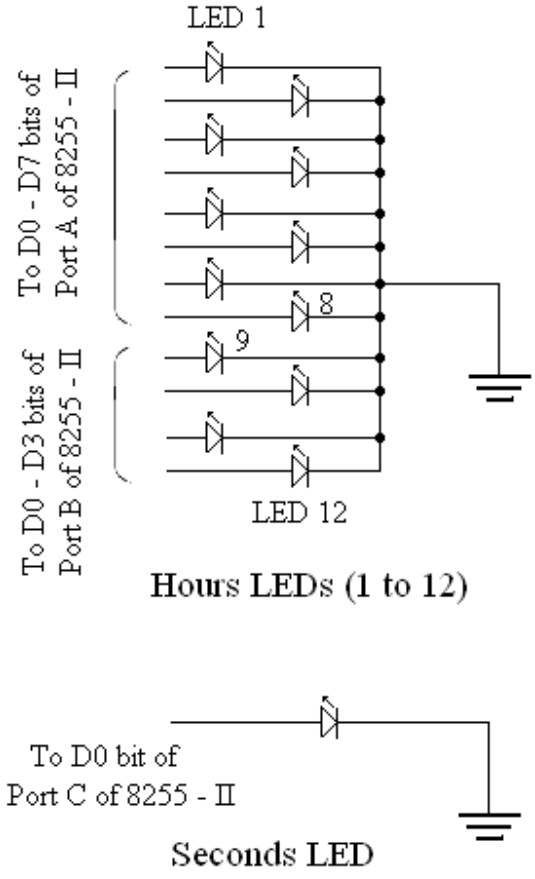

Fig. 15.3

The minutes red colored 60 LEDs are divided into 6 Groups (Group 0 to Group 5) and each group contains 10 LEDs. The cathodes of each group are connected together. The D0 – D5 bits of Port B of 8255 – I are connected to the cathodes (Common Points) of Group 0 to Group 5 LEDs respectively. The ground signal is provided to the cathode pin of each Group through the software using Look up table 15.2.

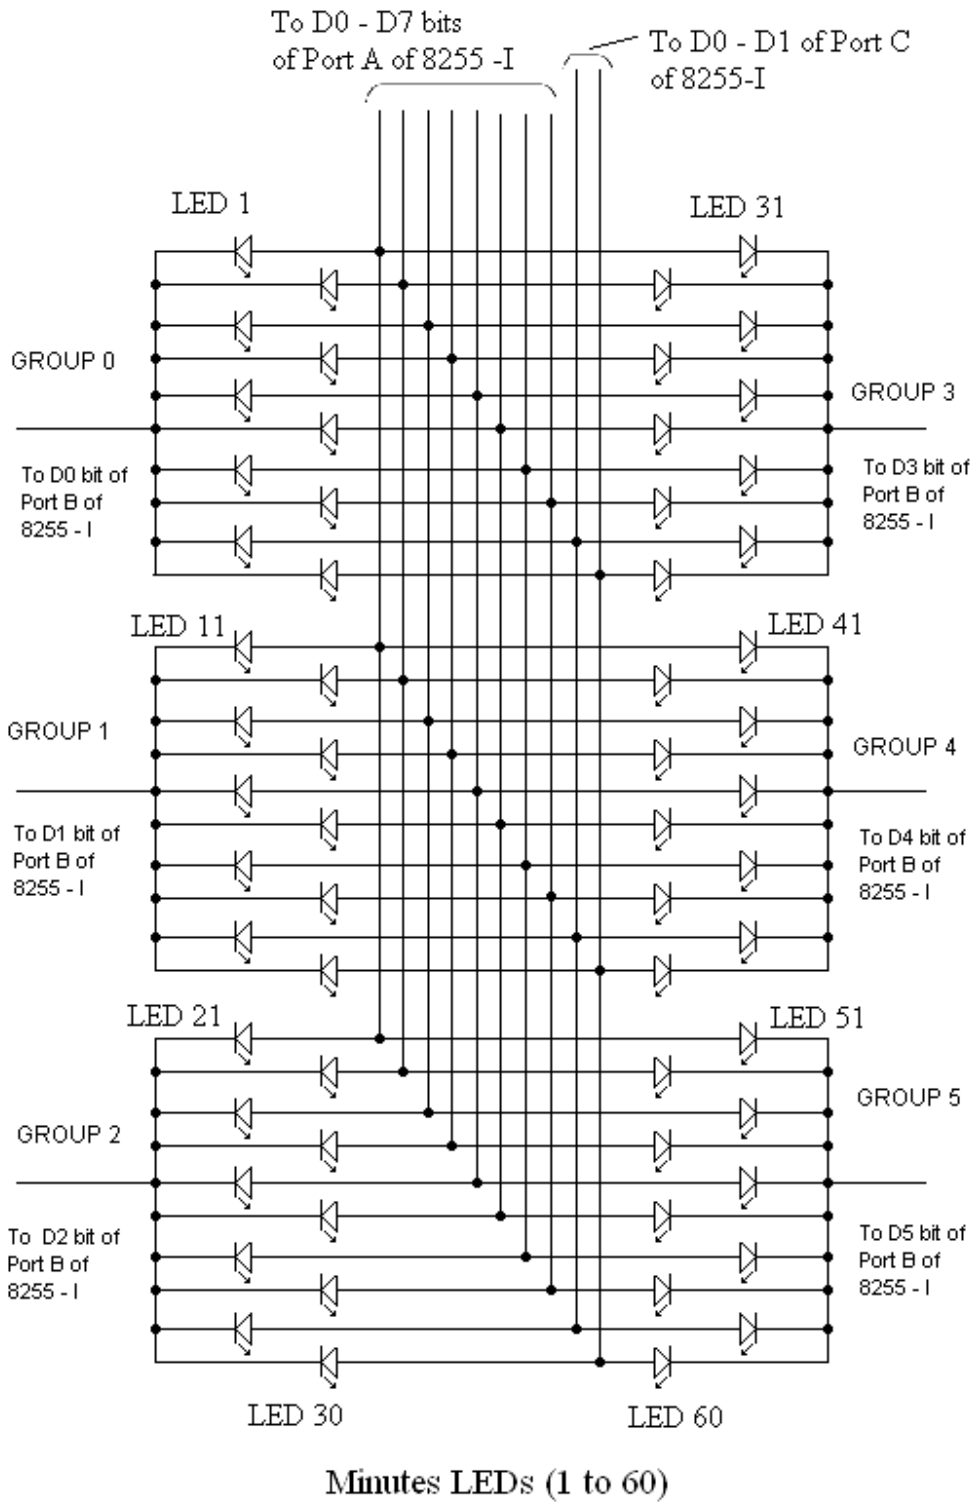

Fig. 15.4

The anodes of 10 LEDs (1 to 10) of each of 6 Groups are connected in parallel, i.e. LED No. 1 of each Group is connected together, and similarly LED No 2 of each

Group is connected together and so on. In this way 10 different Anode leads (1 to 10) are finally available to be connected to different pins of Port A and Port C of 8255 – I. D0 – D7 bits of Port A of 8255 – I are connected to 1 – 8 Anodes leads and 9 – 10 Anode leads are connected to D0 – D1 bits of Port C of 8255– I respectively. Look up table III provides Logic 1 to 1 – 8 Anode Leads; and to the 9 – 10 Anode leads the Logic 1, is provided by the software.

Table –15.1

Memory Location	Data Stores	Binary Equivalent	Comments (Port A of 8255-II)
2101 H	01H	0000 0001	Provides Logic 1 to D0 bit (Hrs.1)
2102 H	02H	0000 0010	Provides Logic 1 to D1 bit (Hrs.2)
2103 H	04H	0000 0100	Provides Logic 1 to D2 bit (Hrs.3)
2104 H	08H	0000 1000	Provides Logic 1 to D3 bit (Hrs.4)
2105 H	10H	0001 0000	Provides Logic 1 to D4 bit (Hrs.5)
2106 H	20H	0010 0000	Provides Logic 1 to D5 bit (Hrs.6)
2107 H	40H	0100 0000	Provides Logic 1 to D6 bit (Hrs.7)
2108 H	80H	1000 0000	Provides Logic 1 to D7 bit (Hrs.8)

Table – 15.2

Memory Location	Data Stores	Binary Equivalent	Comments (Port B of 8255 - I)
2200 H	FEH	1111 1110	Provides Logic 0 to D0 bit (Group 0)
2201 H	FDH	1111 1101	Provides Logic 0 to D1 bit (Group 1)
2202 H	FBH	1111 1011	Provides Logic 0 to D2 bit (Group 2)
2203 H	F7H	1111 0111	Provides Logic 0 to D3 bit (Group 3)
2204 H	EFH	1110 1111	Provides Logic 0 to D4 bit (Group 4)
2205 H	DFH	1101 1111	Provides Logic 0 to D5 bit (Group 5)

Table – 15.3

Memory Location	Data Stores	Binary Equivalent	Comments (Port A of 8255 – I)
2300 H	01H	00000001	Provides Logic 1 to D0 bit
2301 H	02H	00000010	Provides Logic 1 to D1 bit
2302 H	04H	00000100	Provides Logic 1 to D2 bit
2303 H	08H	00001000	Provides Logic 1 to D3 bit
2304 H	10H	00010000	Provides Logic 1 to D4 bit
2305 H	20H	00100000	Provides Logic 1 to D5 bit
2306 H	40H	01000000	Provides Logic 1 to D6 bit
2307 H	80H	10000000	Provides Logic 1 to D7 bit

The software provides a signal continuously to Green LED so that it remains ON and OFF alternately for half a second. The minutes 60 LEDs glow one by one after every one minute. Port B of 8255 – I provides a low voltage (0 volt) to the cathodes of one block for 10 minutes and to the anode of these LEDs (1 to 10) are provided positive voltage (logic 1) alternately for one minute through D0 – D7 bits of Port A and D0 – D2 bits of Port B of 8255 – I. However, Hours' 12 Amber colored LEDs glow one by one after every an Hour time, as positive voltage (logic 1) is provided to the anodes of these LEDs after every an Hour. As discussed earlier positive voltage to Hours LEDs (1 to 8) are provided by D0 – D7 bits of Port A of 8255 – II and to Hours LEDs (9 to 12) are provided by D0 –D3 bits of Port B of 8255 – II after every an hour time. All the LEDs glow in a sequence as the minutes and hours hands move in an analog clock.

The current time is stored in the beginning in some memory locations. Hours, minutes and seconds of the current time are stored in the memory locations say 2000 H to 2002 H respectively. Figures 15.5 show the flow chart of the program. The software in the assembly language of 8085A for providing appropriate signal to different LEDs is given below:

Main Program

MEMORY LOCATIONS WHERE CURRENT TIME IS STORED

2000H	-	CURRENT HRS
2001H	-	CURRENT MINUTES
2002H	-	CURRENT SECONDS

Label	Mnemonics	Operand	Comments
	LXI SP,	XXXX H	;Initialize Stack Pointer.

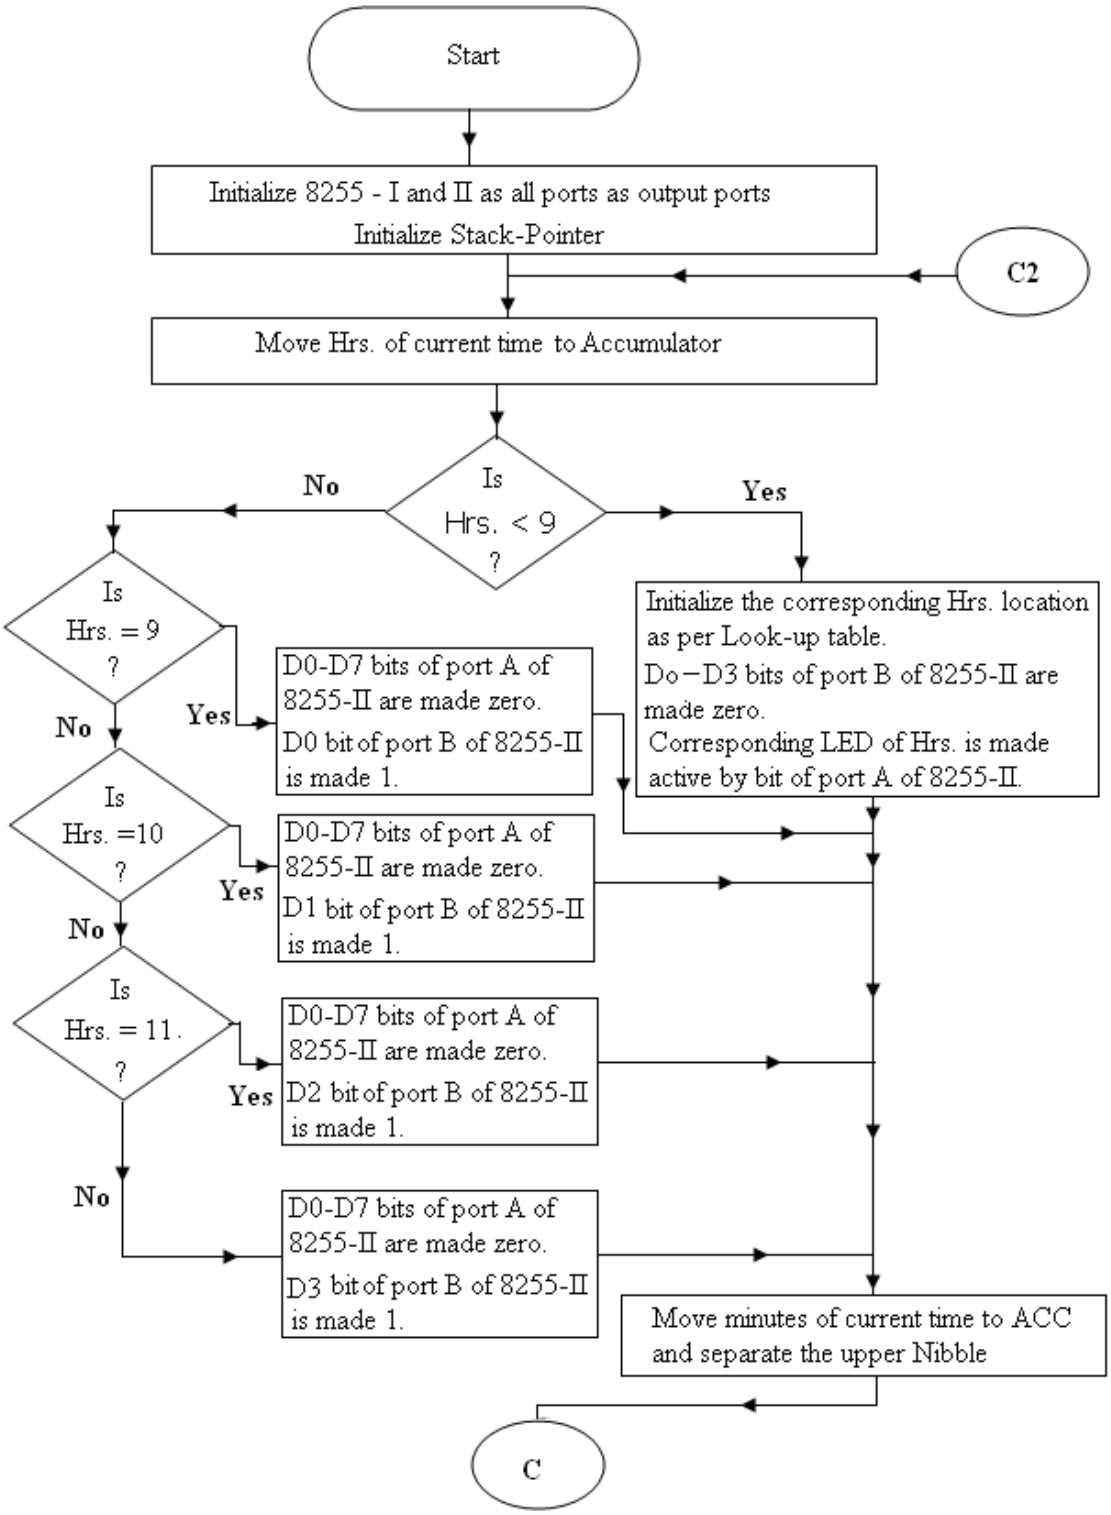
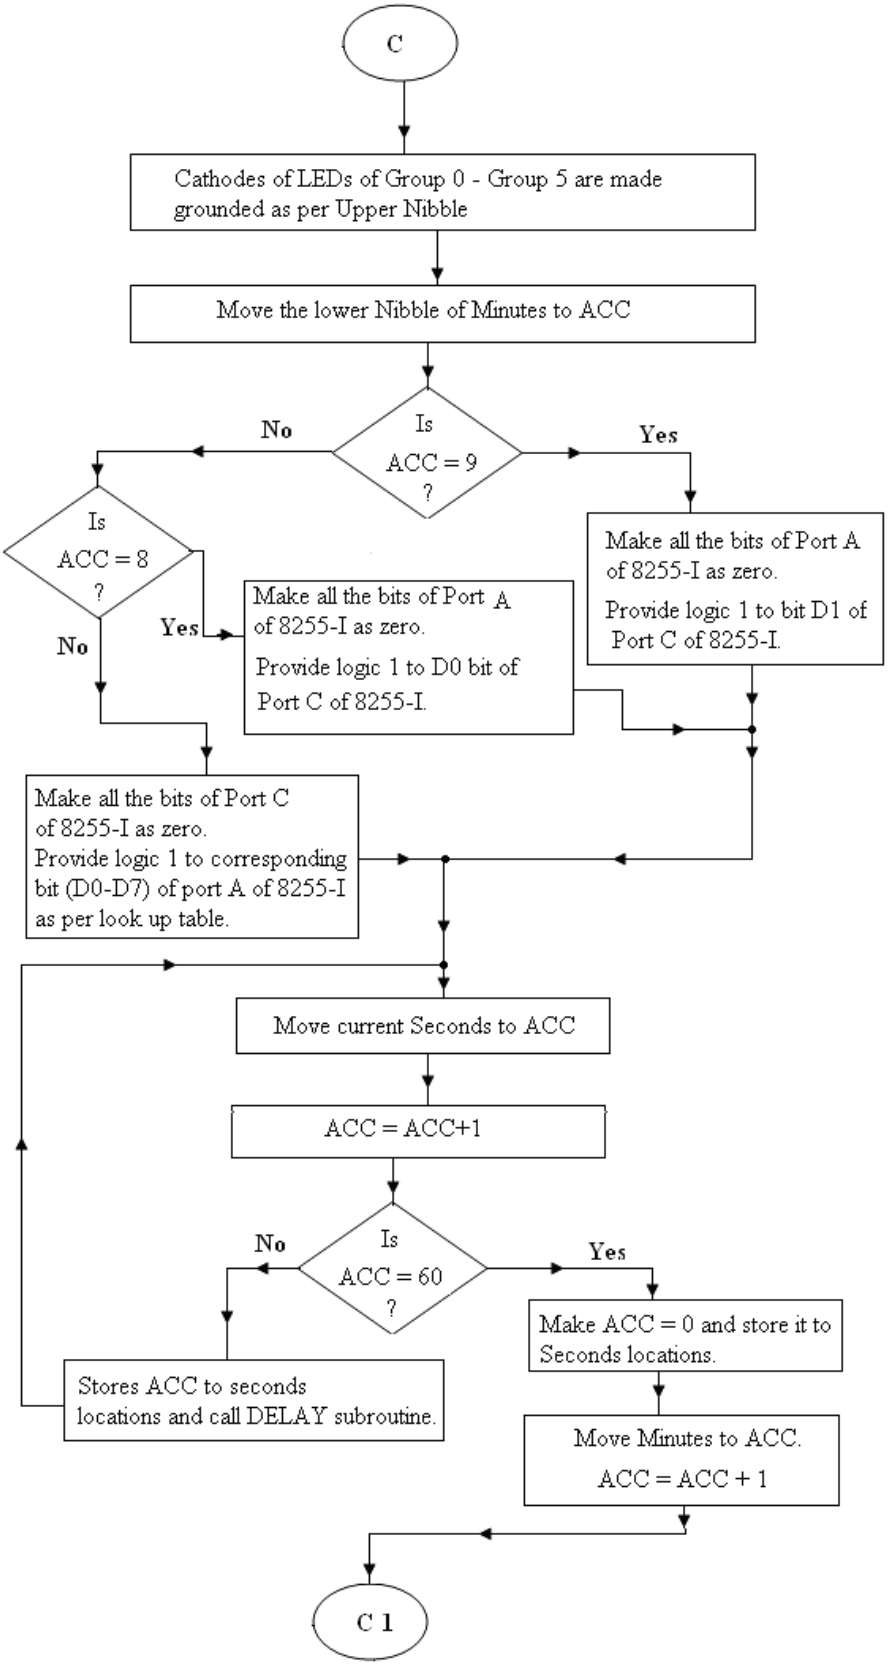
	OUT	03H	;Works all the ports of 8255-I as output port
	OUT	0B H	;Works all the ports of 8255-II as output port.
START	LXI H,	2000 H	;Loads the H-L register pair with the address of Hrs. of current time.
	MOV A,	M	;Moves the Hrs. of current time to accumulator.
	CPI	09 H	;It is compared with 09 H.



Start
Initialize 8255 - I and II as all ports as output ports
Initialize Stack-Pointer
C2
Move Hrs. of current time to Accumulator
Is Hrs. < 9 ?
No
Yes
Initialize the corresponding Hrs. location as per Look-up table.
Do−D3 bits of port B of 8255-II are made zero.
Corresponding LED of Hrs. is made active by bit of port A of 8255-II.
Is Hrs. = 9 ?
Yes
D0-D7 bits of port A of 8255-II are made zero.
D0 bit of port B of 8255-II is made 1.
No
Is Hrs. =10 ?
Yes
D0-D7 bits of port A of 8255-II are made zero.
D1 bit of port B of 8255-II is made 1.
No
Is Hrs. = 11. ?
Yes
D0-D7 bits of port A of 8255-II are made zero.
D2 bit of port B of 8255-II is made 1.
No
D0-D7 bits of port A of 8255-II are made zero.
D3 bit of port B of 8255-II is made 1.
Move minutes of current time to ACC and separate the upper Nibble
C



C
Cathodes of LEDs of Group 0 - Group 5 are made grounded as per Upper Nibble
Move the lower Nibble of Minutes to ACC
Is ACC = 9 ?
No
Yes
Is ACC = 8 ?
Yes
No
Make all the bits of Port A of 8255-I as zero.
Provide logic 1 to bit D1 of Port C of 8255-I.
Make all the bits of Port A of 8255-I as zero.
Provide logic 1 to D0 bit of Port C of 8255-I.
Make all the bits of Port C of 8255-I as zero.
Provide logic 1 to corresponding bit (D0-D7) of port A of 8255-I as per look up table.
Move current Seconds to ACC
ACC = ACC+1
Is ACC = 60 ?
No
Yes
Stores ACC to seconds locations and call DELAY subroutine.
Make ACC = 0 and store it to Seconds locations.
Move Minutes to ACC.
ACC = ACC + 1
C 1

15.3 DESIGN OF MICROPROCESSOR BASED RUNNING LIGHT

The details discussed in the foregoing section of this chapter, may also be used to design the running light. In this project it is expected that 60 lEDs should glow in a sequence one after another in a preset time say one second. The LEDs are connected as shown in figure 15.6. The logic used in this project is the same as in discussed in the microprocessor based dial clock. The assembly language program is self explanatory which is given below. The look-up table for the same is given in table 15.4 and 15.5.

```

15.4 MICROPROCESSOR BASED AUTOMATIC SCHOOL BELL SYSTEM

This is an effective and useful project for educational institutes. In most of educational institutes, the peon rings the bell after every period (usually a period is of 40 minutes duration). The peon has to depend on his wrist watch or clock and sometimes he would even forget to ring the bell in time. In the present system, the human error has been eliminated. Every morning, when the school starts, someone has just to switch on the system and it will thereafter work automatically.

The automatic microprocessor based school bell system presented here has been tested on a Vinytics' microprocessor -8085 kit (VMC-8506). The kit displays the period number on two most significant digits of address field and minutes of the period elapsed on the next two digits of the address field. The data field of the kit displays seconds continuously.

The idea used here is very simple. The programmable peripheral interfacing (PPI) IC INTEL 8255-I available with the kit has been used. The bit 0 of port A (PA0) is connected to the base of a transistor through a resistance as shown in figure 15.7. It is used to energize the relay when PA0 pin of 8255-I is high. The siren, hooter or any bell voice system with an audio amplifier of proper wattage (along with 2 to 3 loudspeakers)

may be installed in the school campus. The relay would get energized after every 40 minutes for a few seconds (say 6 Seconds).

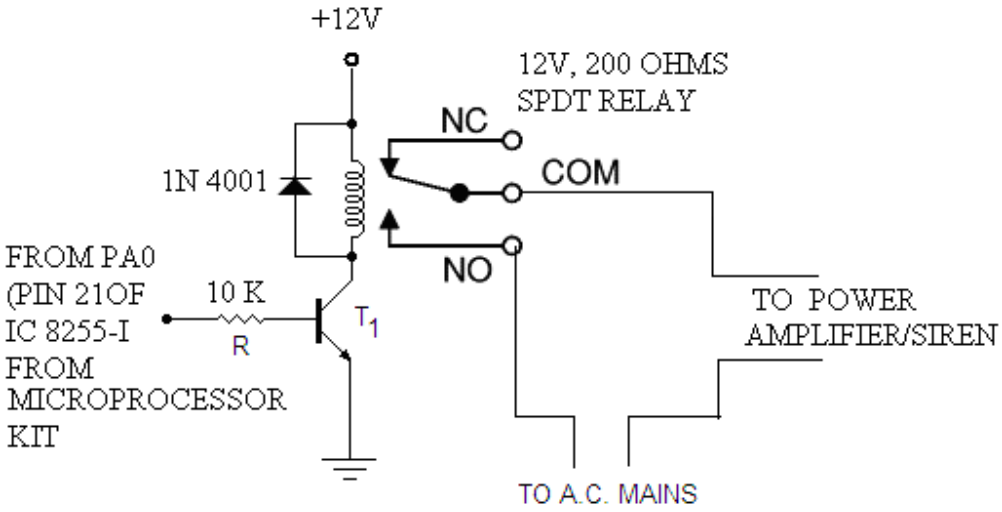

Fig. 15.7

The assembly language program and data used for the purpose are given below in the mnemonic and machine code. The program is self explanatory.

DATA TO BE FILLED BEFORE THE EXECUTION OF THE PROGRAM

2050 H	00	MSD OF PERIOD NO. IS STORED 00.
2051 H	00	LSD OF PERIOD NO. IS STORED 00.
2052 H	00	MSD OF MINUTES IS STORED 00.
2053 H	00	LSD OF MINUTES IS STORED 00.
2054 H	00	MSD OF SECONDS IS STORED 00.
2055 H	00	LSD OF SECONDS IS STORED 00.

First, the program and data are entered in the microprocessor kit. When the program is run a bell sound will be heard for few seconds (say 6 seconds). This will be repeated after every 40 minutes. The period number will be displayed in the two higher digits of the address field. The minutes and seconds of the time elapsed will be displayed in the rest two digits of lower digits of address field and two digits of the data field.

The address and data fields of the microprocessor kit would display the period number and elapsed minutes and seconds in the address and data fields as given below (fig. 15.8). This figure indicate that period No. is 1, minutes and seconds elapsed are 0, 0 respectively.

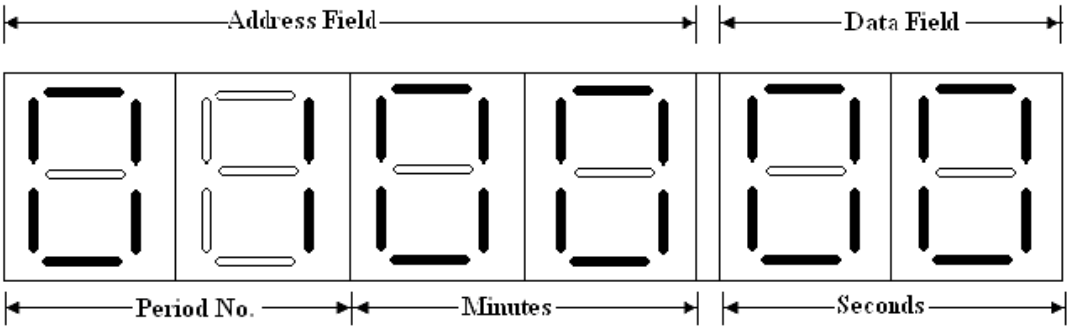

Fig. 15.8

15.5 MICROPROCESSOR BASED TRAFFIC LIGHT

The traffic light controller, which is generally seen at the crossing of the roads, may be designed using the assembly language programming of the microprocessor 8085A. The traffic light controller suggested in this section uses four sets of three LEDs (red, yellow and green) arranged at the four sides of the crossing as shown in figure 15.9. The microprocessor kit (M/S Vinytics) was used to design the traffic light controller.

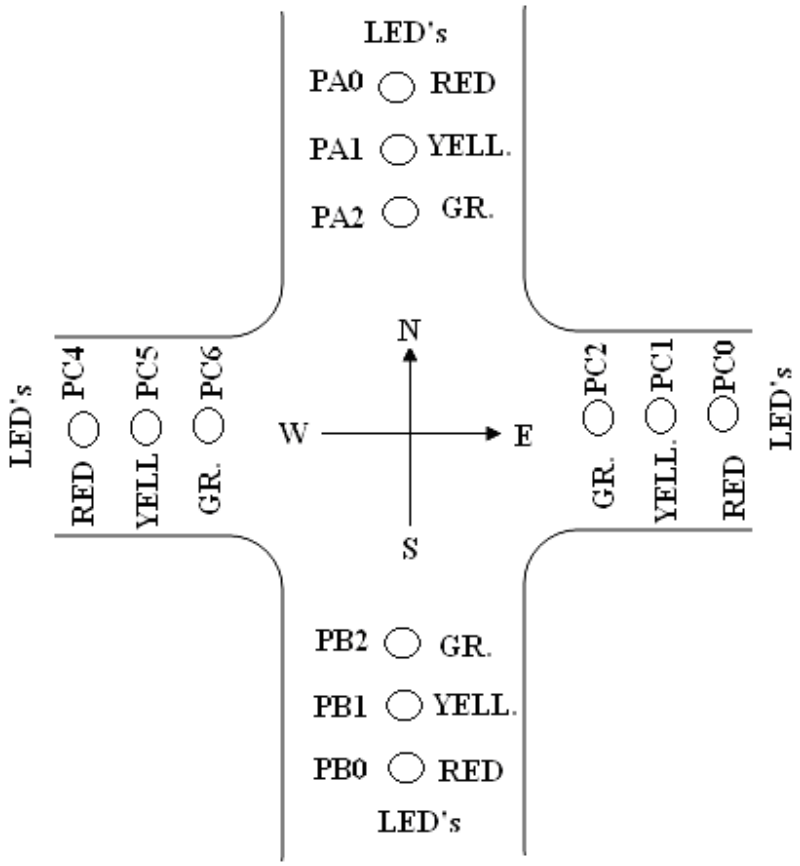

Fig. 15.9

The ports of PPI 8255-I (Port A, Port B, Port C_{Lower} and Port C_{Upper}) available with the kit were used as the output ports. The Red, Yellow and Green LEDs of North are connected to PA_0, PA_1 and PA_2 (bits 0, 1 and 2 of port A) pins of 8255-I respectively. The bits 0, 1, 2 of port B (PB_0, PB_1 and PB_2) were connected to the red, yellow and green LEDs of South respectively. Similarly, PC_0, PC_1 and PC_2 of port C_{Lower} and PC_4, PC_5 and PC_6 of port C_{Upper} were connected to the red, yellow and green LEDs of East and West sides.

Now the following four points occurs for the traffic to control:

(1) First traffic to east west direction is allowed for some time (delay time of 60 seconds say) and traffic to north and south side is not allowed for the sane delay time. This is possible if Red LEDs of north and south (PA_0 and PB_0 both are high) and Green LEDs of East and West (PC_2 and PC_6 are also high) glow.

(2) The yellow lights of east-west and north-south sides are allowed to glow to clear the traffic of these directions for some time (say 20 seconds). The green LEDs of east and west, and red LEDs of north and south are to be remained off for the same time. This condition will be satisfied if PC_1 and PC_5, and PA_1 and PB_1 are high; and PA_0 and PB_0, PC_2 and PC_6 are low.

(3) Now the traffic to north and south side is allowed for the delay time of 60 seconds and traffic to east west direction is not allowed for the sane delay time. This is possible if green LEDs of north and south (PA_2 and PB_2 both are high) and red LEDs of East and West (PC_0 and PC_4 are also high) glow.

(4) Again the yellow lights of east-west and north-south sides are allowed to glow to clear the traffic of these directions for some time (say 20 seconds). The green LEDs of north and south, and red LEDs of east and west are to be remained off for the same time. This condition will be satisfied if PC_1 and PC_5, and PA_1 and PB_1 are high.

The assembly language program for the above conditions is given below, which is self explanatory:

Label	**Mnemonics**	**Operand**	**Comments**
	LXI SP,	XXXX H	;Initialize the stack pointer.
	MVI A,	80H	;Control word for 8255-I.

                        south glows).
CALL        DELAY I   ; Delay program of 60
                        seconds.
MVI A,      22 H
OUT         02 H      ; PC1 and PC5 are high
                        (Yellow LEDs of east and
                        west glow).
MVI A,      02 H
OUT         00 H      ; PA1 is high (yellow LED
                        of north glows).
OUT         01 H      ; PB1 is high (yellow LED
                        of south glows).
CALL        DELAY II  ; Delay  program of 20
                        seconds.
JMP         AGAIN     ; Jump to repeat the program
                        from the beginning.
```

Subroutine programs to introduce delay for 6o seconds and 20 seconds are given below:

Subroutine Program for DELAY I

Label	Mnemonics	Operand	Comments
DELAY I	MVI B,	78 H	;78 H (120 decimal number) is loaded to B register for the loop.
YY	LXI D,	FA00 H	
NXT1	DCX	D	;Decrement D-E register pair.
	MOV A,	D	;Moves the contents stored in M_{D-E} to Acc.
	ORA	E	;The contents of A and E registers are ORed bit by bit.
	JNZ		NXT1;If the result is not zero then jump to nxt1 else next instruction.
	DCR	B	:Decrement B register
	JNZ	YY	
	RET		; Returns to main program.

Subroutine Program for DELAY II

Label	Mnemonics	Operand	Comments
DELAY II	MVI B,	28 H	;28 H (40 decimal number) is loaded to B register for the loop.
	JMP	YY	; Jump to YY of DELAY I program.

Figure 15.10 shows the LED connections to 8255-I available with the microprocessor kit.

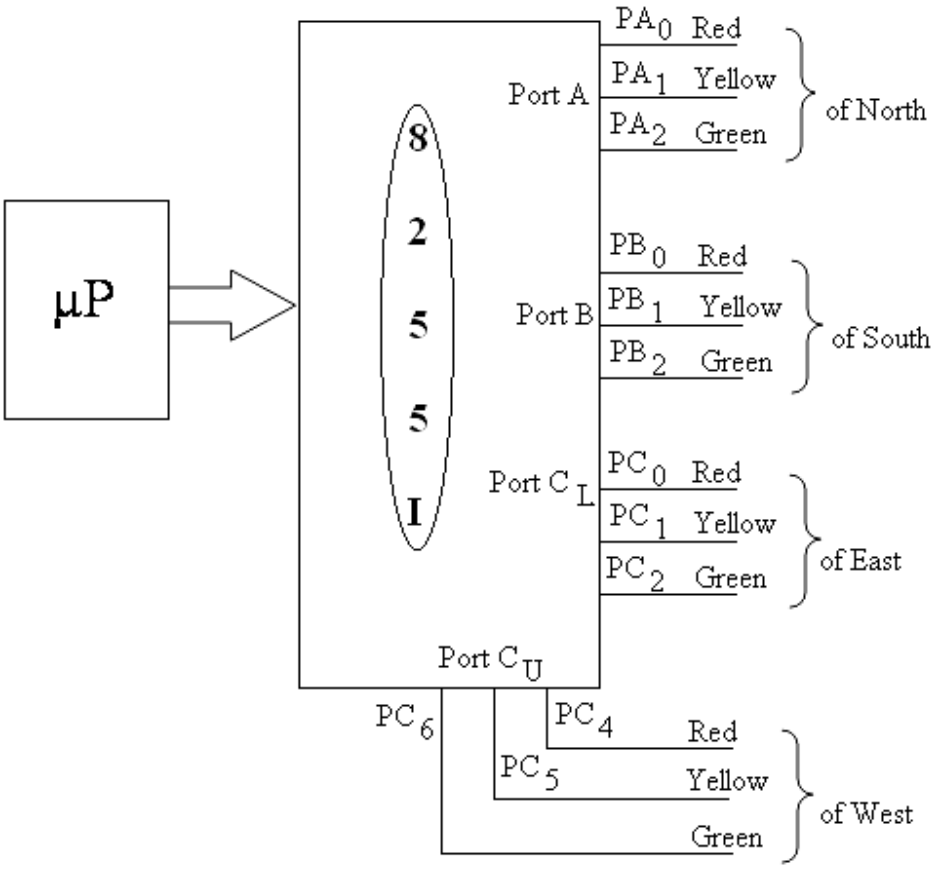

Fig. 15.10

15.5.1 Another Design of Microprocessor Based Traffic Light

Here another design of Traffic light controller is given in which there are more degree of freedom for the traffic. Further, the display of time delay (count down) on the microprocessor kit is also shown. In this design, the divider lines at the four path ways are shown (ref. figure 15.11). At each divider line of four path ways near the crossing, five LEDs (one red, one yellow and three green) are installed on four pillars. These LEDs are connected to the ports of PPI 8255-I available with the microprocessor kit. All the ports of 8255 are used as output ports. The status of LEDs will indicate the direction of the traffic at the crossing.

In this design the delay of 90 seconds are allowed for the normal traffic and say 10 seconds delay is introduced for yellow light to clear the traffic, before the next traffic direction. The delay will be displayed on the data field with down counting. The assembly language programming of the design is given below. The program is simple and self-explanatory.

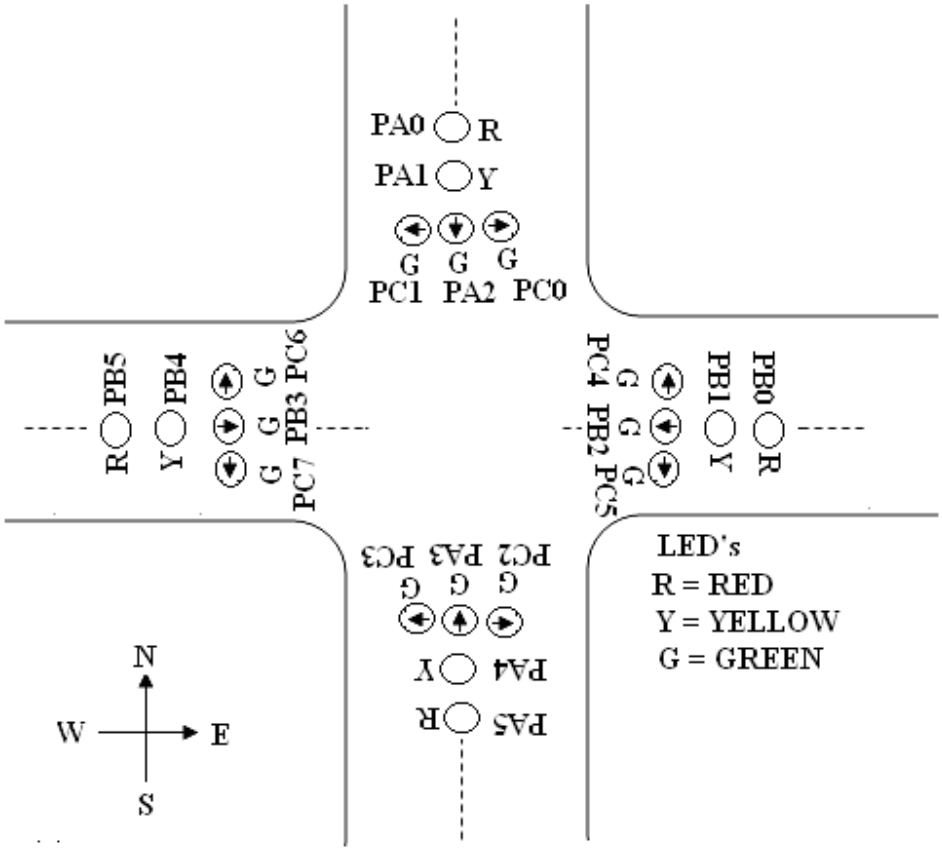

Fig. 15.11

```

15.6 MICROPROCESSOR BASED STEPPER MOTOR CONTROL

In this section the design of microprocessor based stepper motor control will be discussed. The stepper motor has four windings such that the motor rotates in precise steps from one fixed position to another. A stepper motor is an electromechanical device which converts electrical pulses into discrete mechanical movements. The shaft or spindle of a stepper motor rotates in discrete step increments when electrical command pulses are applied to it in the proper sequence. The motor's rotation has several direct relationships to these applied input pulses. The sequence of the applied pulses is directly related to the direction of motor shafts rotation. The speed of the motor shafts rotation is directly related to the frequency of the input pulses and the length of rotation is directly related to the number of input pulses applied. A stepper motor can be a good choice whenever controlled movement is required. They can be used where the control rotation angle, speed, position and synchronism are needed. Because of the inherent advantages

stepper motors have found their place in many different applications. Some of these include printers, plotters, high end office equipment, hard disk drives, medical equipments, fax machines, automotive and many more.

The stepper motor is to be interfaced with microprocessor by 8255A PPI and some buffers/ amplifiers. The four windings (coils) of the stepper motor are shown in figure 15.12. However, figure 15.13 shows the block diagram of the interfacing connections for the stepper motor. One set of coils of the stepper motor is energized using 12 V d. c. supply in the form of pulse. After energizing one set of coil windings some time delay is provided through software, then the supply is given to other set of windings. The speed of the motor will be governed by the delay introduced in the system.

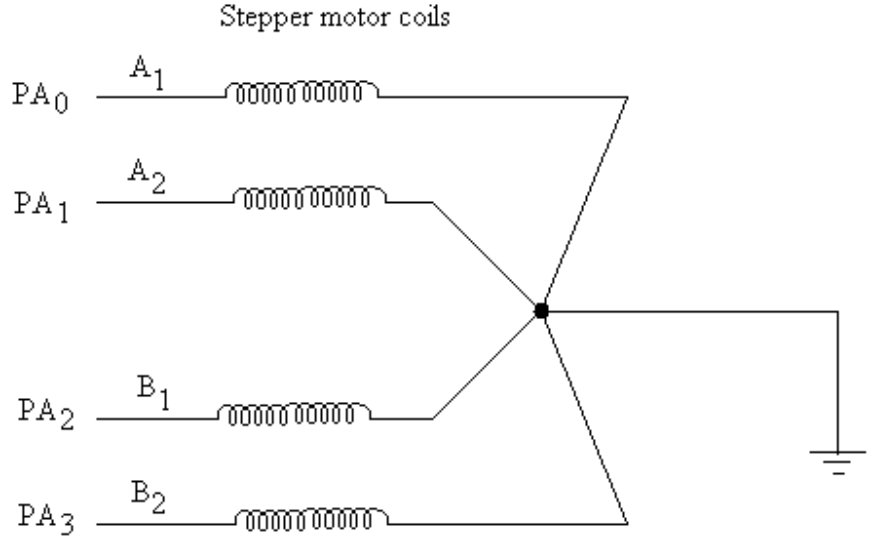

Fig. 15.12

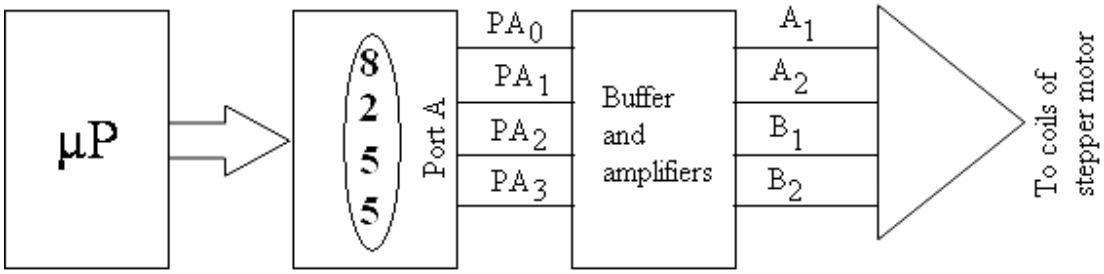

Fig. 15.13

For the clockwise movement of the stepper motor, it is energized in the sequence:

A_1 A_2, **A_2 B_1,** **B_1 B_2,** **B_2 A_1** and then repeats.

Similarly, in the anti-clock wise movement of the stepper motor, it is energized in the sequence:

A_1 A_2, **B_2 A_1,** **B_1 B_2,** **A_2 B_1** and then repeats.

Number of steps or movements, for the stepper motor to be moved, are loaded in the register C. For example the stepper motor to be moved for 20 steps then it equivalent hexadecimal number 14 H is to be loaded this register before the start of the run. Similarly, if the stepper motor is to be rotated in clock wise direction then load 00 in

register B or load 01 in register B if the motor is to be moved in anti-clock wise direction. The flow chart for the movement of the stepper motor is shown in figure 15.14.

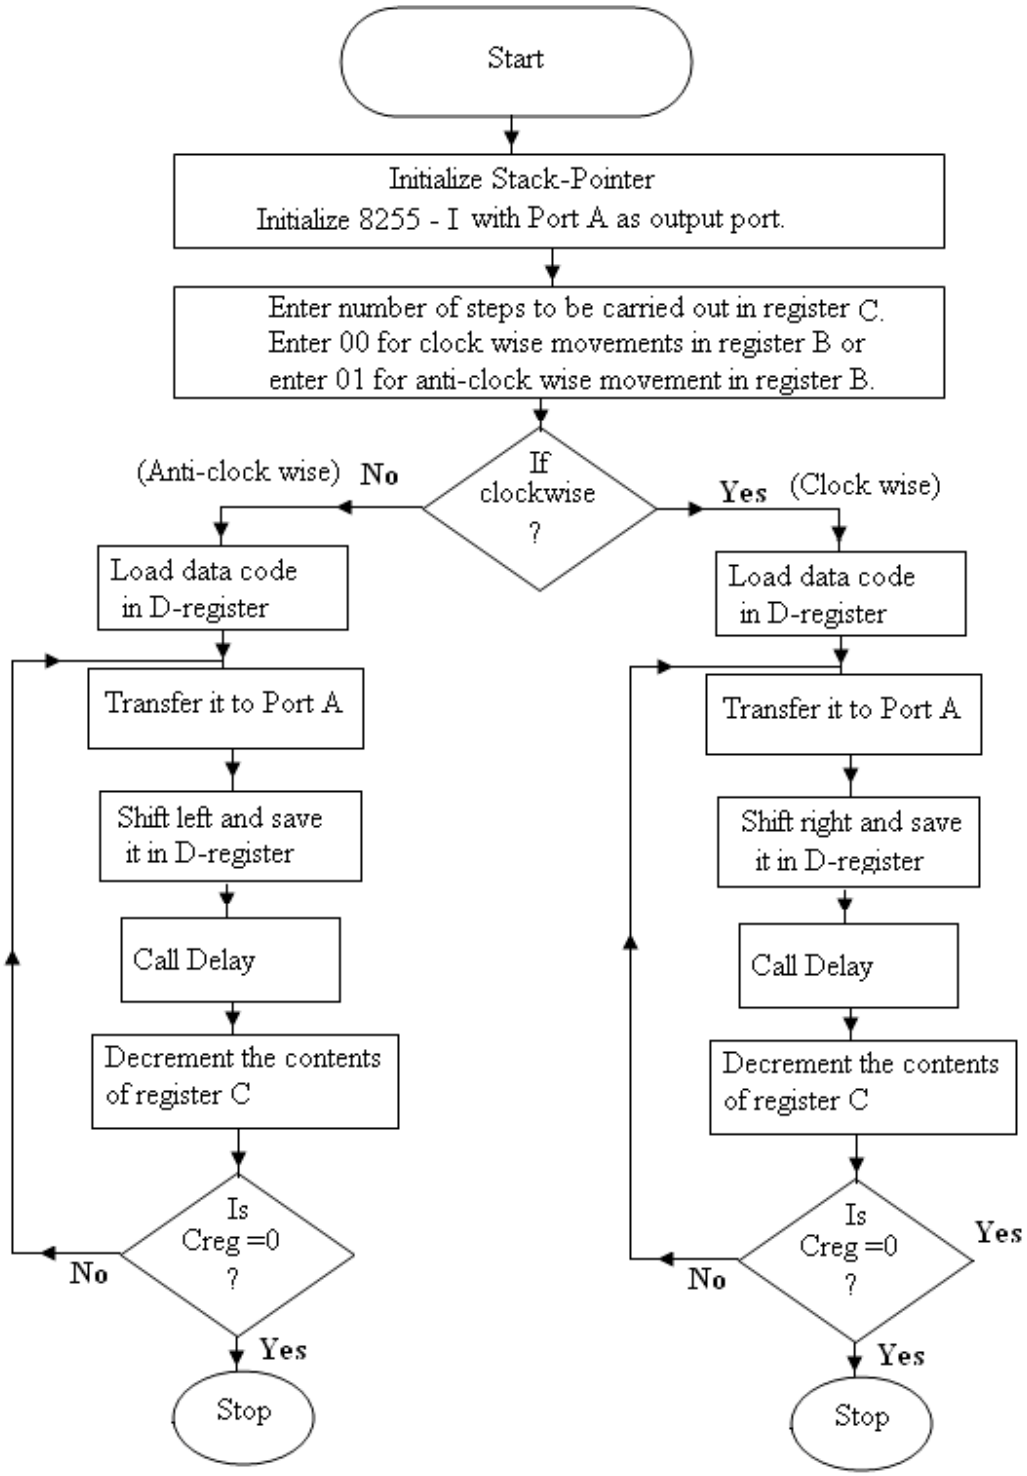

Fig. 15. 14

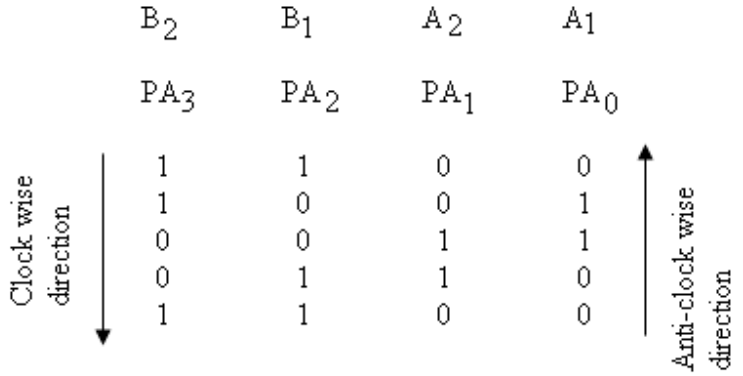
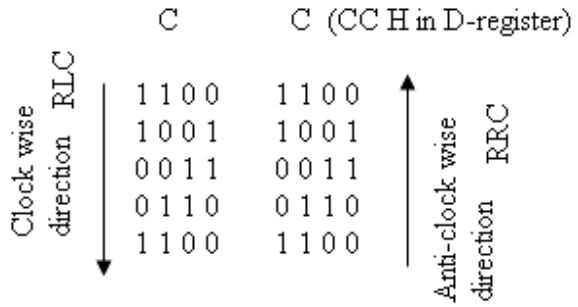
Further, the bits (PA_0, PA_1, PA_2 and PA_3) of port A of 8255A are to be connected to A_1, A_2, B_1 and B_2 coils of the motor respectively. The movements of the motor in clockwise or anti-clock wise direction should be as:



This is possible if CC H is loaded to the D-register and then data is rotated clockwise or anti-clock wise direction with RRC or RLC instructions as shown below:



The assembly language program for the above description is given below which is self explanatory:

Label	**Mnemonics**	**Operand**	**Comments**
	LXI SP,	XXXX H	;Initialize the stack pointer.
	MVI A,	80H	;Control word for 8255-I.
	OUT	03H	;Works all the ports of 8255-I as output ports.
	MVI C,	14 H	;14 H (20 steps for movement) is loaded to C-register. It is used as counter.
	MVI B,	YY H	; YY may be 00 H or 01 H for clockwise or anti-clock wise direction respectively.
	MOV A,	B	; Move the contents of B-register to accumulator.

```
        CPI     01 H        ; Check if movement is
                              clockwise or anti-clock
                              wise.

                          for delay as per the
                          requirement.
POP  B                  ; Get back the content of B-
                          C register pair from the
                          Stack.
POP  D                  ; Get back the content of D-
                          E register pair from the
                          Stack.
POP  PSW                ; Get back the  Acc and flag
                          content from the Stack.
DCR         C           ; Decrement in number of
                          counts.
JNZ         LOOP2       ; If counts are not 0 then
                          jump to LOOP2 for next
                          movement.
HLT                     ; stop processing.
```

Subroutine programs to introduce delay for required time may be written as discussed earlier.

15.7 MICROPROCESSOR BASED WASHING MACHINE CONTROLLER

The automatic washing machines available in the market are microprocessor based. Here conditional sequences are considered which are controlled by microprocessor along with interfacing devices. It basically involves trigger inputs as well as specific delays. In other words there are some trigger inputs which leads the washing machine to work with certain time delays as well.

The port A and Port B of 8255-I are used for the purpose of control of certain functions of washing machine. Let the bits D0 and D1 of port A are used for introducing time delay for certain time as given below:

D1 D0

0	0	No time delay required.
0	1	Delay 1 for certain time delay (say for t1)
1	0	Delay 2 for certain other time delay (say for t2 seconds)
1	1	Not used

D2 bit of the Port A is used for the tub motor rotating at the drying speed.
D3 bit of the port A is used for water outlet.
D4 bit of this port is used for the tub motor rotating at wash or rinse speed.
D5 bit of this port is used for water inlet.
D6 and D7 bits are not used.

The devices connected to the Port A of 8255-I for the purpose of controlling events during the operation of washing machine are as given in figure 15. 15

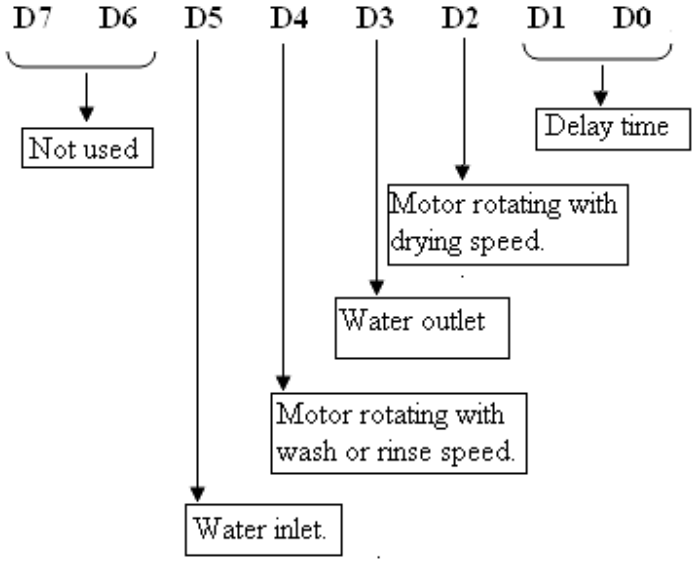

Fig. 15.15

Consider a water level sensor connected with a D1 bit of port B of 8255-I. The port B is used as the input port which will indicate if the water is filled to the specified level.

The sequence of events to be undertaken during the operation of washing machine is as given below:

1. The tub is filled with water up to the specified level with the water inlet. The level of the water will be sensed by the water level sensor.
2. The tub is rotated at wash or rinse speed for a fixed time t1.
3. The tub is allowed to empty for a fixed time t2.
4. The tub is filled again with water up to a specified level whose level will be sensed with water level sensor.
5. The tub is rotated again with wash or rinse speed for the fixed time t1.

6. The tub is allowed to empty again for a fixed time t2.
7. Switch on dryer for time t1.

Figure 15.16 shows the flow chart for the sequence of events to be carried out during the washing machine operation.

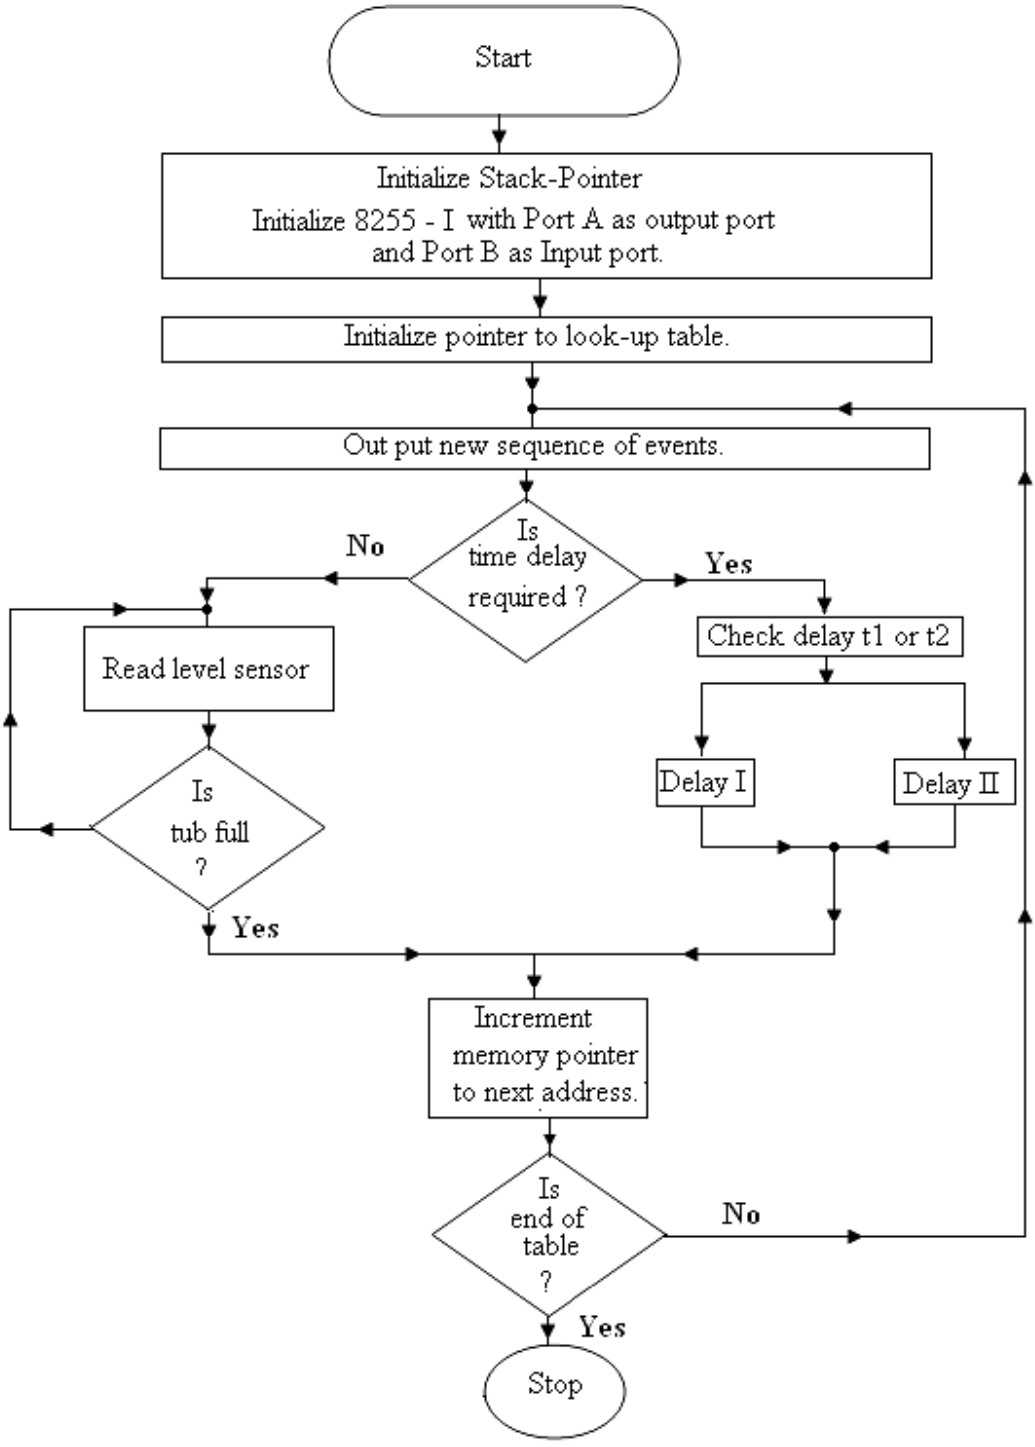
The assembly language program for the above mentioned sequence of events is given below:

Label	**Mnemonics**	**Operand**	**Comments**
	LXI SP,	XXXX H	;Initialize the stack pointer.
	MVI A,	82 H	;Control word for 8255-I.
	OUT	03 H	;Works port A of 8255-I as output ports and port B as input port.
	LXI H,	2500 H	; Initialize H-L register pair which indicate address of the look-up table.
NEXT 1	MOV A,	M	; Get the data from the address of the look-up table.
	OUT	00 H	; The accumulator contents go the port A of 8255-I.
	ANI	03 H	; Check if delay required.
	JZ	NEXT	; If the delay is not required jump to NEXT.
	ANI	02 H	; Check if delay-II is required.
	JZ	SB	; If yes jump to SB.
	CALL	DELAY I	; Call delay program of t1 seconds.
	JMP	PT1	; Jump to PT1.
SB	CALL	DELAY II	; Call delay program of t2.
	JMP	PT1	; Jump to PT1.
NEXT	INX	H	; Get the address of next data from the look-up table.
LOOP	IN	01 H	; Get the input from the water level sensor.
	SUB	M	; Check if the water level is equal to the required level.
	JNZ	LOOP	; If no jump to LOOP.
PT1	INX	H	; Get the address of next data from the look-up table.
	MOV A,	M	; Data is moved to Acc.
	CPI	00 H	; Data is compared with 00.

```
        JNZ         NEXT 1      ; If not zero jump to
                                  NEXT1.
        HLT                     ; Else Halt.
```

Subroutine program for DELAY I:

Label	**Mnemonics**	**Operand**	**Comments**
DELAY I	LXI D,	FFFF H	
LOOP 1	DCX	D	;Decrement D-E register pair.
	MOV A,	D	;Moves the contents stored in M_{D-E} to Acc.
	ORA	E	;The contents of A and E registers are ORed bit by bit.
	JNZ	LOOP 1	;If the result is not zero then jump to DELAY else next instruction.
	RET		;Return to main program.



Start
Initialize Stack-Pointer
Initialize 8255 - I with Port A as output port
and Port B as Input port.
Initialize pointer to look-up table.
Out put new sequence of events.
Is time delay required ?
No
Yes
Read level sensor
Check delay t1 or t2
Delay I
Delay II
Is tub full ?
Yes
Increment memory pointer to next address.
Is end of table ?
No
Yes
Stop

Fig. 15.16

Subroutine program for DELAY II

Label	Mnemonics	Operand	Comments
DELAY II	LXI D,	DEEE H	
LOOP 2	DCX	D	; Decrement D-E register pair.
	MOV A,	D	; Moves the contents stored in M_{D-E} to Acc.
	ORA	E	; The contents of A and E registers are ORed bit by bit.
	JNZ	LOOP 2	; If the result is not zero then jump to DELAY else next instruction.
	RET		; Return to main program.

15.8 MICROPROCESSOR BASED WATER LEVEL CONTROLLER

Water level controller means water is to be pump out from the underground water tank to the anther water tank situated on the top of the building for the distribution of water to the other parts of the building. When the upper tank is empty or the level goes below to a certain level, the pump should be automatically switched on. Further, if the tank gets filled up to a certain level (top level) the pump should be switched off. The level of the water inside the upper water tank should be displayed on the seven segment units connected separately with the microprocessor kit. For this the tank to be filled is divided in to 8 equal regions which are say 10 cm apart. So at every 10 cm, a metallic probe is situated.

The arrangement of 8 probes which are to be immersed in the water tank is shown in figure 15.17. For the controller 8 metallic probes connected to +5 V d.c. supply through resistance are immersed in the upper tank. The difference in heights between the probes is equal to 10 cm (say). Besides the probe, another metallic strip is also immersed in the tank, which is grounded. The eight probes are also connected to the inputs of 8 inverters as shown in figure 15.18. The outputs of the inverters are connected to 8 bits of port A of 8255-I, which is used as input port. When any of the probes is immersed in the water (or water level is below the probe), the output of the corresponding inverter will provide a logic 0 to its bit of port A. However, if the water level touches the probe or above the probe, then it provides logic 1 to the corresponding bit of port A. The status of water level in the upper tank can directly be read by the microprocessor through the input statement. For example, if only one probe is immersed in the water, then port A of 8255-I will read it 01, similarly for the others. Table 15.4 shows the data to be read out by 8255-I, when different probes are immersed in the water.

When the water level of the tank is below 10 cm, the pump is automatically switched on; however, when its level reaches to 80 cm, the pump will be switched off.

Figure 15.19 shows the connection to the two segment display units connected to the port B of 8255-I for displaying the level of water in the upper tank in centimeters i.e. if the water level is between 1 and 2 probe, then the display unit will display 10, similarly for the other levels (ref. table 15.4).

Table 15.4

Sr.No.	Probe number/ numbers immersed in water	Data to be read out by the microprocessor		Level in cms.

The assembly language program for the design of water level controller with the above mentioned conditions is given below, which is self explanatory.

Label	**Mnemonics**	**Operand**	**Comments**
	LXI SP,	XXXX H	;Initialize the stack pointer.
	MVI A,	90H	;Control word for 8255-I.
	OUT	03H	;Works port A of 8255-I as input port and other ports as output ports.
START	IN	00 H	; Read the water level through input port A.
	LXI H,	25FF H	; Intilise the H-L register pair (starting address of the look up table).
	MOV C,	M	; Data is moved to C-register which is used as counter.
AGAIN	INX	H	; Increment the H-L register pair.
	CMP	M	; Compare the two levels.
	JZ	PT1	; If two levels are equal, then jump to PT1.
	DCR	C	; Decrement the counts.

```
        JNZ     AGAIN   ; If counts are not zero then
                          jump to AGAIN.
PT1     INR     H       ; Increment the content of
                          H-register.
        MOV A,  M       ; Get the water level in
                          Accumulator.
        OUT     01 H    ; Move it to Port B of 8255-I
                          for the display.
        CPI     10 H    ; Compare this data with 10
                          cm.
        JNC     NXT     ; If the water is more than 10
                          cm, then move it to NXT.
        PUSH    PSW     ; Else save the Acc contents
                          in the stack.
        MVI A,  01 H    ; 01 H is loaded to the
                          accumulator.
        OUT     02 H    ; PC0 is high (Switch on the
                          motor for lifting the water).
        POP     PSW     ; Get back the accumulator
                          contents from the stack.
NXT     CPI     80 H    ; Compared the data with 80
                          cm.
        JC      START   ; If the data is less than 60,
                          then jump to START.
        MVI A,  00 H    ; 00 H is loaded to the
                          accumulator.
        OUT     02 H    ; PC0 is low (Switch off the
                          motor).
        CALL    DELAY   ; Calls delay program.
        JMP     START   ; Jump to start.
```

Delay Program may be written as discussed in earlier program as per the requirement.

2707 H	70 H	(70 Cm.)
2708 H	80 H	(80 Cm.)

15.9 MICROPROCESSOR BASED TEMPERATURE CONTROLLER

In this section a very simple design of temperature controller is being discussed. The temperature of water bath or of any other device is to be controlled or maintained constant. This is possible if the a.c. mains supplied to the device is switched off if the temperature of the device is more than the required temperature; and it is switched on if the temperature is less than the required temperature. A temperature sensor may be used to sense the temperature of the device. The sensor (say a thermocouple) may provide the thermo e.m.f. (d.c. signal) corresponding to the temperature. The d.c. signal may be converted to the digital signal with the help of A/D converter IC 0809. The output of the A/D converter can be read by the microprocessor through the 8255 PPI.

The arrangement for the control is shown in figure 15.20. Channel 0 of A/D converter is used to convert the sensor voltage to equivalent digital signal. This digital signal can be read out by the microprocessor 8085A through port A (used as input port) of 8255-I provided on the microprocessor kit. Port C_{Lower} of 8255 is used as output port to send the SOC (Start of Conversion) signal and other bits for the channel selection of A/D converter 0809. For the selection of channel 0 ALE (Address Latch Enable) and SOC are made high by the output port C_{Lower} of 8255. Port C_{Upper} of 8255 is uses as output port. Before reading the input data (digital value) by the microprocessor, EOC (End of Conversion) signal PC7 is checked for logic 1.The bit PB0 of port B (used as output port) of 8255 may be used to control the heating arrangement of the device through the relay system.

Before running the assembly language program, it is to be calibrated as per the sensor used in this arrangement. Note down the temperature and digital value (in Hexadecimal) which may be stored in some memory locations as a look-up table. This look-up table may be used for the display of the temperature on the address/data field of the microprocessor kit using its monitor program. The digital data of the temperature of the device to be maintained constant, may be saved in a memory location say 2500 H. By comparing the current data (of temperature) with the saved (or required) data, the electrical heating system may be switched on/off.

Figure 15.21 shows the flow chart for the controller.

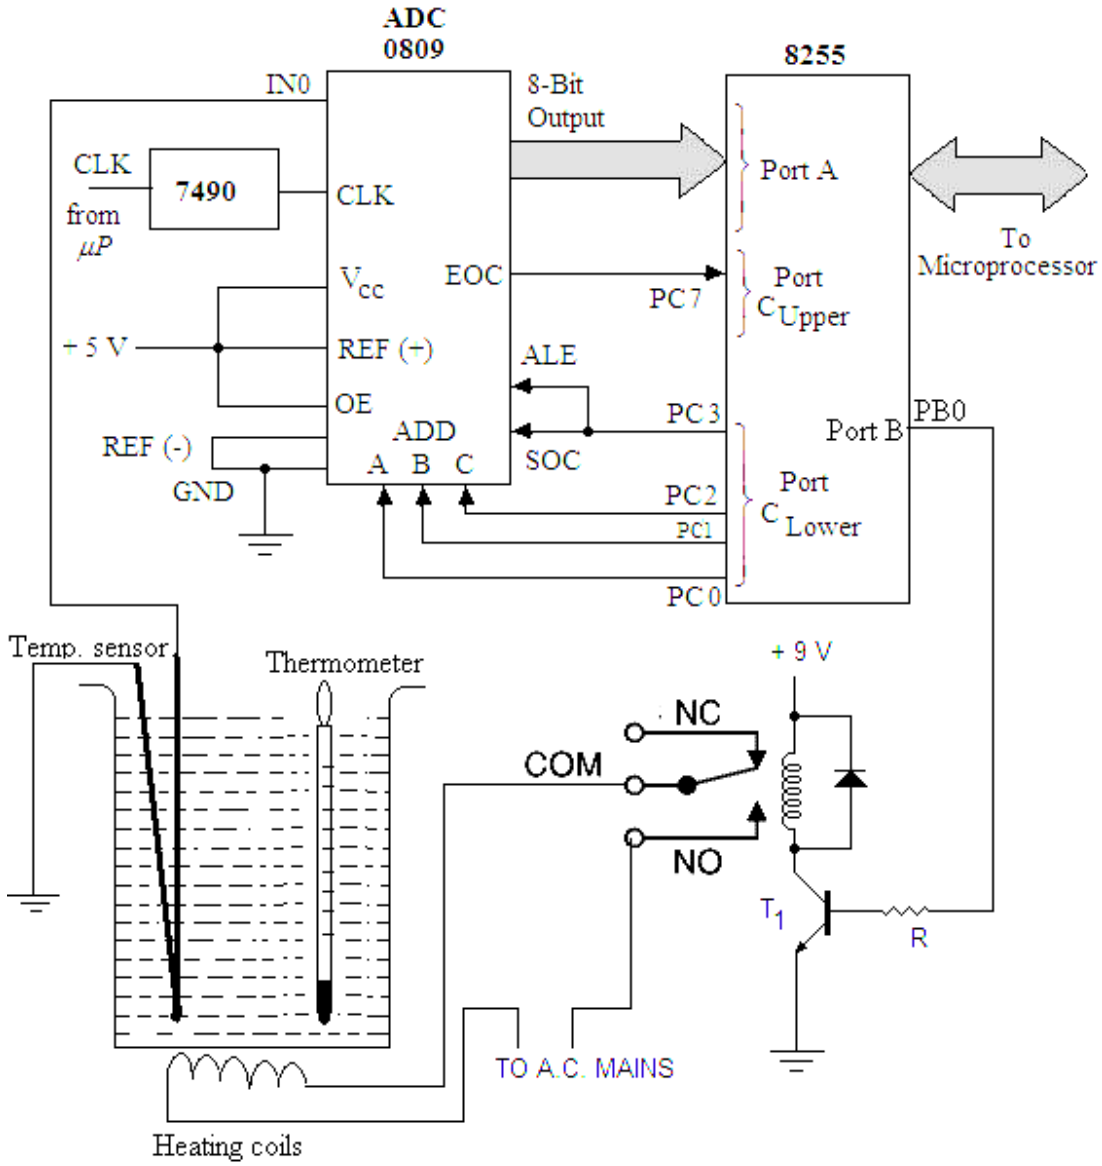

Fig. 15.20

PROGRAM

Label	**Mnemonics**	**operand**	**Comments**
	MVI	A, 98 H	; Initialize 8255-I to work Port A and Port C_{Upper} as input ports, and port C_{Lower} as output port.
	OUT	03 H	; Write the control word in the control word register of 8255-I.
	LXI H,	2500 H	; Initialize H-L register pair for address where required temp. T is saved.

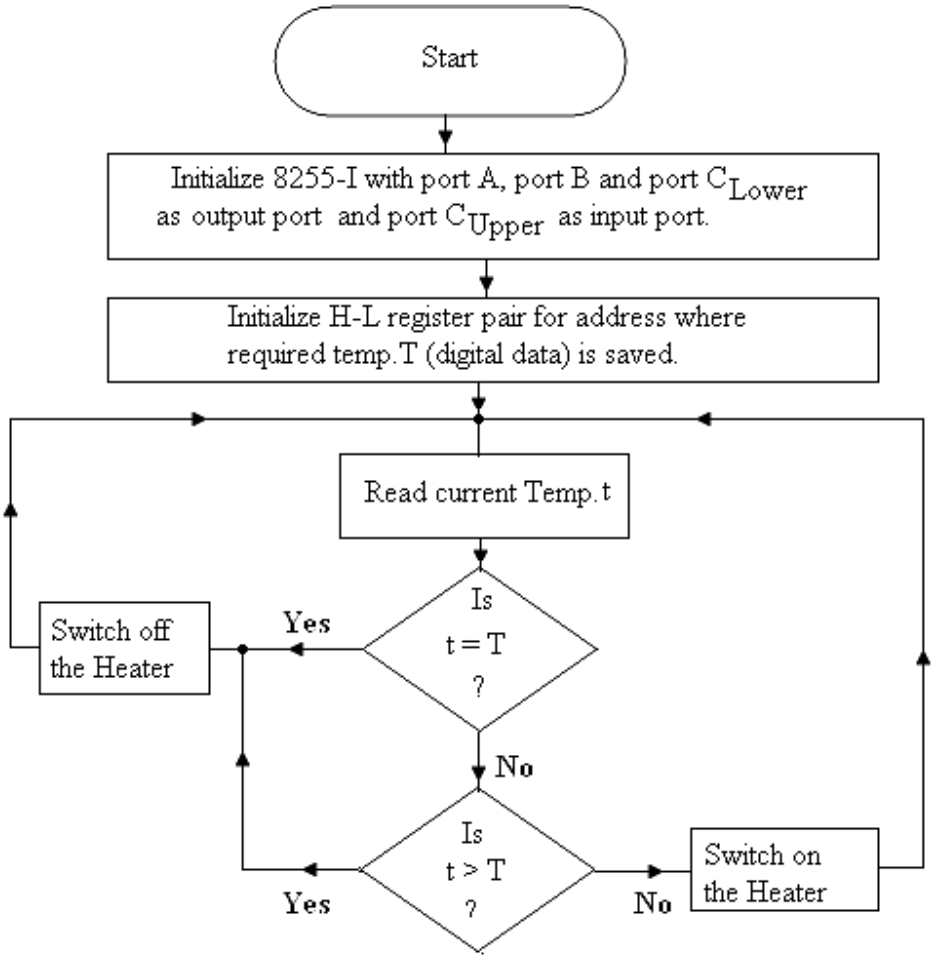

Fig. 15.21

START	MVI	A, 00 H	; Load accumulator with 00H.
	OUT	02 H	; 00H is sent to Port C_{Lower} to select channel 0.
	MVI	A, 08 H	; Load 08 H to accumulator.
	OUT	02 H	; ALE and SOC are enabled (high).
	MVI	A, 00 H	; Load 00 H to accumulator.
	OUT	02 H	; ALE and SOC will be low. A pulse is applied from high to low for the conversion through PC_3 without affecting the channel selected.
READ	IN	02 H	; Read End of conversion (PC_7).
	RAL		; Rotate left to check if PC_7 is one.
	JNC	READ	; If not 1 READ again.
	IN	00 H	; Read digital output of the A/D converter (Temp. t).

```
        STA     2501 H      ; Store the result in 2501 H memory
                            location.
        CMP     M           ; Compare the two temperatures for
                            equality.
        JNZ     NEXT        ; If not equal then jump to NEXT.
LOOP1   MVI A,  00 H        ; Switch off the heater.
        OUT     01 H        ; PB0 is low.
        JMP     START       ; Jump to START.
NEXT    SUB     M           ; Check if t>T ?
        JNC     LOOP1       ; If yes then jump to LOOP1.
        MVI A,  01 H        ; Switch on the heater.
        OUT     01 H        ; PB0 is high.
        JMP     START       ; Jump to START.
```

PROBLEMS

1. How will you design the digital clock on the microprocessor kit? Hours and minutes should be displayed on the address field and seconds should be displayed on the data field. Monitor programs of the kit may be used for the display of time. Write program in assembly language of 8085.
2. Design the digital clock which can display the time in 24 hours form on the microprocessor kit. Write program in assembly language of 8085.
3. In problem 1, on time should also be introduced. Write program in assembly language of 8085.
4. Discuss the design of microprocessor based LED dial clock. Write program in assembly language of 8085.
5. Discuss the design of microprocessor based running light in which some LEDs can run in a sequence. Write program in assembly language of 8085.
6. Discuss the design of microprocessor based school bell system. Write program in assembly language of 8085.
7. Discuss the design of microprocessor based Traffic light (simple arrangement). Write program in assembly language of 8085.
8. Discuss the design of microprocessor based Traffic light (complicated arrangement) in which traffic is allowed in left-right direction also. Write program in assembly language of 8085.
9. In the above design of microprocessor based traffic light, the delay time should also be displayed on the address and data field of the microprocessor kit. Write program in assembly language of 8085.
10. Discuss the design of microprocessor based Stepper Motor controller. Write program in assembly language of 8085.
11. Write program in assembly language of 8085 to control the different function of washing machine.

12. Discuss the water level controller which can pump out the water from the underground tank to the tank placed on the roof of the building. The motor of the pump should be switched on if the water level in the upper tank is less than certain level. The pump should be switched off when the water level in the upper tank is completely filled. Program for same should be written in assembly language of the 8085 microprocessor.
13. Discuss the design of microprocessor based Temperature controller which can maintain the temperature of a device constant. Write program in assembly language of 8085.

Changes for the Twelfth Edition of Concepts of Programming Languages

- **Chapter 2**: Added Section 2.16.4 A Replacement for Objective-C: Swift
    - Added Section 2.16.5 Another Related Language: Delphi
    - Deleted Section 2.18.6 Origins and Characteristics of Lua
- **Chapter 5**: Rewrote several paragraphs in Section 5.5.3 to correct and clarify
- **Chapter 6**: Added a paragraph to Section 6.3.2 to describe support for strings in Swift
    - Added a paragraph to Section 6.4.2 to describe support the enumeration types in Swift
    - Added a paragraph to Section 6.5.3 to describe support for arrays in Swift
    - Added a paragraph to Section 6.6.1 to describe support for associative arrays in Swift
    - Deleted the interview in Section 6.6.1
    - Added Section 6.12 Optional Types
- **Chapter 8**: Added a design issue and a brief discussion of it to Section 8.3.1.1
    - Added several paragraphs to Section 8.3.4 that describe iterators in

Python

- **Chapter 9**: Added a paragraph to Section 9.5.4 on Swift parameters
- **Chapter 11**: Deleted Section 11.4.2 (Abstract Data Types in Objective-C)
- **Chapter 12**: Deleted Section 12.4.5 (Objective-C)
    - Deleted Objective-C column from Table 12.1
    - Added a paragraph in the Summary on reflection

Preface

Changes for the Twelfth Edition

The goals, overall structure, and approach of this twelfth edition of *Concepts of Programming Languages* remains the same as those of the eleven previous editions. The principal goals are to introduce the fundamental constructs of contemporary programming languages and to provide the reader with the tools necessary for the critical evaluation of existing and future programming languages. A secondary goal is to prepare the reader for the study of compiler design, by providing an in-depth discussion of programming language structures, presenting a formal method of describing syntax, and introducing approaches to lexical and syntax analysis.

The twelfth edition evolved from the eleventh through several different kinds of changes. To maintain the currency of the material, nearly all discussion of some programming languages, specifically Lua and Objective-C, has been removed. Material on the newer language, Swift, was added to several chapters.

In addition, a new section on optional types was added to Chapter 6. Material was added to Section 8.3.4 to describe iterators in Python. In numerous places in the manuscript small changes were made to correct and/or clarify the discussion.

The Vision

This book describes the fundamental concepts of programming languages by discussing the design issues of the various language constructs, examining the design choices for these constructs in some of the most common languages, and critically comparing design alternatives.

Any serious study of programming languages requires an examination of some related topics, among which are formal methods of describing the syntax and semantics of programming languages, which are covered in Chapter 3. Also, implementation techniques for various language constructs must be considered: Lexical and syntax analysis are discussed in Chapter 4, and implementation of subprogram linkage is covered in Chapter 10. Implementation of some other language constructs is discussed in various other parts of the book.

The following paragraphs outline the contents of the twelfth edition.

Chapter Outlines

Chapter 1 begins with a rationale for studying programming languages. It then discusses the criteria used for evaluating programming languages and language constructs. The primary influences on language design, common design trade-offs, and the basic approaches to implementation are also examined.

Chapter 2 outlines the evolution of the languages that are discussed in this book. Although no attempt is made to describe any language completely, the origins, purposes, and contributions of each are discussed. This historical overview is valuable, because it provides the background necessary to understanding the practical and theoretical basis for contemporary language design. It also motivates further study of language design and evaluation. Because none of the remainder of the book depends on Chapter 2, it can be read on its own, independent of the other chapters.

Chapter 3 describes the primary formal method for describing the syntax of programming language—BNF. This is followed by a description of attribute grammars, which describe both the syntax and static semantics of languages. The difficult task of semantic description is then explored, including brief introductions to the three most common methods: operational, denotational, and axiomatic semantics.

Chapter 4 introduces lexical and syntax analysis. This chapter is targeted to those Computer Science departments that no longer require a compiler design course in their curricula. Similar to Chapter 2, this chapter stands alone and can be studied independently of the rest of the book, except for Chapter 3, on which it depends.

Chapters 5 through 14 describe in detail the design issues for the primary constructs of programming languages. In each case, the design choices for several example languages are presented and evaluated. Specifically, Chapter 5 covers the many characteristics of variables, Chapter 6 covers data types, and Chapter 7 explains expressions and assignment statements. Chapter 8

describes control statements, and Chapters 9 and 10 discuss subprograms and their implementation. Chapter 11 examines data abstraction facilities. Chapter 12 provides an in-depth discussion of language features that support object-oriented programming (inheritance and dynamic method binding), Chapter 13 discusses concurrent program units, and Chapter 14 is about exception handling, along with a brief discussion of event handling.

Chapters 15 and 16 describe two of the most important alternative programming paradigms: functional programming and logic programming. However, some of the data structures and control constructs of functional programming languages are discussed in Chapters 6 and 8. Chapter 15 presents an introduction to Scheme, including descriptions of some of its primitive functions, special forms, and functional forms, as well as some examples of simple functions written in Scheme. Brief introductions to ML, Haskell, and F# are given to illustrate some different directions in functional language design. Chapter 16 introduces logic programming and the logic programming language, Prolog.

To the Instructor

Chapters 1 and 3 are typically covered in detail, and though students find it interesting and beneficial reading, Chapter 2 receives little lecture time due to its lack of hard technical content. Because no material in subsequent chapters depends on Chapter 2, as noted earlier, it can be skipped entirely. If a course in compiler design is required, Chapter 4 is not covered.

Chapters 5 through 9 should be relatively easy for students with extensive programming experience in C++, Java, or C#. Chapters 10 through 14 are more challenging and require more detailed lectures.

Chapters 15 and 16 are entirely new to most students at the junior level. Ideally, language processors for Scheme and Prolog should be available for students required to learn the material in these chapters. Sufficient material is included to allow students to dabble with some simple programs.

Undergraduate courses will probably not be able to cover all of the material

in the last two chapters. Graduate courses, however, should be able to completely discuss the material in those chapters by skipping over some parts of the early chapters on imperative languages.

Supplemental Materials

The following supplements are available to all readers of this book at *www.pearson.com/cs-resources*.

- A set of lecture note slides. PowerPoint slides are available for each chapter in the book.
- All of the figures from the book.

A companion Web site to the book is available at *www.pearson.com/cs-resources*. This site contains mini-manuals (approximately 100-page tutorials) on a handful of languages.

Solutions to many of the problem sets are available to qualified instructors in our Instructor Resource Center at *www.pearson.com*. Please contact your school's Pearson representative or visit *www.pearson.com* to register.

Language Processor Availability

Processors for and information about some of the programming languages discussed in this book can be found at the following Web sites:

C, C++, Fortran, and Ada	*gcc.gnu.org*
C# and F#	*microsoft.com*
Java	*java.sun.com*
Haskell	*haskell.org*
Scheme	*www.plt-scheme.org/software/drscheme*
Perl	*www.perl.com*
Python	*www.python.org*
Ruby	*www.ruby-lang.org*

JavaScript is included in virtually all browsers; PHP is included in virtually all Web servers.

All this information is also included on the companion Web site.

Acknowledgments

The suggestions from outstanding reviewers contributed greatly to this book’s present form and contents. In alphabetical order, they are:

Numerous other people provided input for the previous editions of *Concepts of Programming Languages* at various stages of its development. All of their comments were useful and greatly appreciated. In alphabetical order, they are: Vicki Allan, Henry Bauer, Carter Bays, Manuel E. Bermudez, Peter Brouwer, Margaret Burnett, Paosheng Chang, Liang Cheng, John Crenshaw, Charles Dana, Barbara Ann Griem, Mary Lou Haag, John V. Harrison, Eileen Head, Ralph C. Hilzer, Eric Joanis, Leon Jololian, Hikyoo Koh, Jiang B. Liu, Meiliu Lu, Jon Mauney, Robert McCoard, Dennis L. Mumaugh, Michael G. Murphy, Andrew Oldroyd, Young Park, Rebecca Parsons, Steve J. Phelps, Jeffery Popyack, Steven Rapkin, Hamilton Richard, Tom Sager, Raghvinder - Sangwan, Joseph Schell, Sibylle Schupp, Mary Louise Soffa, Neelam Soundarajan, Ryan Stansifer, Steve Stevenson, Virginia Teller, Yang Wang, John M. Weiss, Franck Xia, and Salih Yurnas.

Matt Goldstein, Portfolio Management Specialist; Meghan Jacoby, Portfolio Management Assistant; Managing Content Producer, Scott Disanno; and Prathiba Rajagopal, all deserve my gratitude for their efforts to produce the twelfth edition both quickly and carefully.

About the Author

Robert Sebesta is an Associate Professor Emeritus in the Computer Science Department at the University of Colorado–Colorado Springs. Professor Sebesta received a BS in applied mathematics from the University of Colorado in Boulder and MS and PhD degrees in computer science from Pennsylvania State University. He has taught computer science for more than 40 years. His professional interests are the design and evaluation of programming languages and Web programming.

Contents

CONCEPTS OF PROGRAMMING LANGUAGES

TWELFTH EDITION

1 Preliminaries

Before we begin discussing the concepts of programming languages, we must consider a few preliminaries. First, we explain some reasons why computer science students and professional software developers should study general approaches to language design and evaluation. This discussion is especially valuable for those who believe that a working knowledge of one or two programming languages is sufficient for computer scientists. Then, we briefly describe the major programming domains. Next, because the book evaluates language constructs and features, we present a list of criteria that can serve as a basis for such judgments. Then, we discuss the two major influences on language design: machine architecture and program design methodologies. After that, we introduce the major categories of programming languages. Next, we describe a few of the most important trade-offs that must be - considered during language design.

Because this book is also about the implementation of programming - languages, this chapter includes an overview of the most common general approaches to implementation. Finally, we briefly describe a few examples of programming environments and discuss their impact on software production.

1.1 Reasons for Studying Concepts of Programming Languages

It is natural for students to wonder how they will benefit from the study of programming language concepts. After all, many other topics in computer - science are worthy of serious study. In fact, many now believe that there are more important areas of computing for study than can be covered in a four-year college curriculum. The following is what we believe to be a compelling list of potential benefits of studying concepts of programming languages:

- Increased capacity to express ideas. It is widely believed that the depth at which people can think is influenced by the expressive power of the language in which they communicate their thoughts. Those with only a weak understanding of natural language are limited in the complexity of their thoughts, particularly in depth of abstraction. In other words, it is difficult for people to conceptualize structures they cannot describe, verbally or in writing.

  Programmers, in the process of developing software, are similarly constrained. The language in which they develop software places limits on the kinds of control structures, data structures, and abstractions they can use; thus, the forms of algorithms they can construct are likewise limited. Awareness of a wider variety of programming language features can reduce such limitations in software development. Programmers can increase the range of their software development thought processes by learning new language constructs.

  It might be argued that learning the capabilities of other languages does not help a programmer who is forced to use a language that lacks those capabilities. That argument does not hold up, however, because often, - language constructs can be simulated in other languages that do not support those constructs directly. For example, a C (Harbison and Steele, 2002) programmer who had learned the structure and uses of associative arrays in Perl (Christianson et al., 2013) might design

structures that simulate associative arrays in that language. In other words, the study of programming language concepts builds an appreciation for valuable language features and constructs and encourages programmers to use them, even when the language they are using does not directly support such features and constructs.

- Improved background for choosing appropriate languages. Some professional programmers have had little formal education in computer science; rather, they have developed their programming skills independently or through in-house training programs. Such training programs often limit instruction to one or two languages that are directly relevant to the current projects of the organization. Other programmers received their formal training years ago. The languages they learned then are no longer widely used, and many features now available in programming languages were not commonly known at the time. The result is that many programmers, when given a choice of languages for a new project, use the language with which they are most familiar, even if it is poorly suited for the project at hand. If these programmers were familiar with a wider range of languages and language constructs, they would be better able to choose the language with the features that best address the problem.

  Some of the features of one language often can be simulated in another language. However, it is preferable to use a feature whose design has been integrated into a language than to use a simulation of that feature, which is often less elegant, more cumbersome, and less safe.

- Increased ability to learn new languages. Computer programming is still a relatively young discipline, and design methodologies, software development tools, and programming languages are still in a state of continuous evolution. This makes software development an exciting profession, but it also means that continuous learning is essential. The process of learning a new programming language can be lengthy and difficult, especially for someone who is comfortable with only one or two languages and has never examined programming language concepts in general. Once a thorough understanding of the fundamental concepts of languages is acquired, it becomes far easier to see how these concepts

are incorporated into the design of the language being learned. For example, programmers who understand the concepts of object-oriented programming will have a much easier time learning Ruby (Thomas et al., 2013) than those who have never used those concepts.

The same phenomenon occurs in natural languages. The better you know the grammar of your native language, the easier it is to learn a second language. Furthermore, learning a second language has the benefit of teaching you more about your first language.

The TIOBE Programming Community issues an index (`http://www.tiobe.com/index.php/content/paperinfo/tpci/index.htm`) that is an indicator of the relative popularity of programming languages. For example, according to the index, Java, C, C++ (Lippman et al., 2012), and C# (Albahari and Abrahari, 2012) were the four most popular languages in use in February 2017.1 However, dozens of other languages were widely used at the time. The index data also show that the distribution of usage of programming languages is always changing. The number of languages in use and the dynamic nature of the statistics imply that every software developer must be prepared to learn different languages.

1. Note that this index is only one measure of the popularity of programming languages, and its accuracy is not universally accepted.

Finally, it is essential that practicing programmers know the vocabulary and fundamental concepts of programming languages so they can read and understand programming language descriptions and evaluations, as well as promotional literature for languages and compilers. These are the sources of information needed in order to choose and learn a language.

- Better understanding of the significance of implementation. In learning the concepts of programming languages, it is both interesting and necessary to touch on the implementation issues that affect those concepts. In some cases, an understanding of implementation issues leads to an understanding of why languages are designed the way they are. In turn, this knowledge leads to the ability to use a language more intelligently, as it was designed to be used. We can become better

programmers by understanding the choices among programming language constructs and the consequences of those choices.

Certain kinds of program bugs can be found and fixed only by a programmer who knows some related implementation details. Another benefit of understanding implementation issues is that it allows us to visualize how a computer executes various language constructs. In some cases, some knowledge of implementation issues provides hints about the relative efficiency of alternative constructs that may be chosen for a program. For example, programmers who know little about the complexity of the implementation of subprogram calls often do not realize that a small subprogram that is frequently called can be a highly inefficient design choice.

Because this book touches on only a few of the issues of implementation, the previous two paragraphs also serve well as rationale for studying compiler design.

- Better use of languages that are already known. Most contemporary programming languages are large and complex. Accordingly, it is uncommon for a programmer to be familiar with and use all of the features of a language he or she uses. By studying the concepts of programming languages, programmers can learn about previously unknown and unused parts of the languages they already use and begin to use those features.

- Overall advancement of computing. Finally, there is a global view of computing that can justify the study of programming language concepts. Although it is usually possible to determine why a particular programming language became popular, many believe, at least in retrospect, that the most popular languages are not always the best available. In some cases, it might be concluded that a language became widely used, at least in part, because those in positions to choose languages were not sufficiently familiar with programming language concepts.

  For example, many people believe it would have been better if ALGOL 60 (Backus et al., 1963) had displaced Fortran (ISO/IEC 1539-1, 2010)

in the early 1960s, because it was more elegant and had much better control statements, among other reasons. That it did not, is due partly to the programmers and software development managers of that time, many of whom did not clearly understand the conceptual design of ALGOL 60. They found its description difficult to read (which it was) and even more difficult to understand. They did not appreciate the benefits of block structure, recursion, and well-structured control statements, so they failed to see the benefits of ALGOL 60 over Fortran.

Of course, many other factors contributed to the lack of acceptance of ALGOL 60, as we will see in Chapter 2. However, the fact that computer users were generally unaware of the benefits of the language played a significant role.

In general, if those who choose languages were well informed, perhaps better languages would eventually squeeze out poorer ones.

1.2 Programming Domains

Computers have been applied to a myriad of different areas, from controlling nuclear power plants to providing video games in mobile phones. Because of this great diversity in computer use, programming languages with very different goals have been developed. In this section, we briefly discuss a few of the most common areas of computer applications and their associated languages.

1.2.1 Scientific Applications

The first digital computers, which appeared in the late 1940s and early 1950s, were invented and used for scientific applications. Typically, the scientific applications of that time used relatively simple data structures, but required large numbers of floating-point arithmetic computations. The most common data structures were arrays and matrices; the most common control structures were counting loops and selections. The early high-level programming languages invented for scientific applications were designed to provide for those needs. Their competition was assembly language, so efficiency was a primary concern. The first language for scientific applications was Fortran. ALGOL 60 and most of its descendants were also intended to be used in this area, although they were designed to be used in related areas as well. For some scientific applications where efficiency is the primary concern, such as those that were common in the 1950s and 1960s, no subsequent language is significantly better than Fortran, which explains why Fortran is still used.

1.2.2 Business Applications

The use of computers for business applications began in the 1950s. Special computers were developed for this purpose, along with special languages. The first successful high-level language for business was COBOL (ISO/IEC, 2002), the initial version of which appeared in 1960. It probably still is the

most commonly used language for these applications. Business languages are characterized by facilities for producing elaborate reports, precise ways of describing and storing decimal numbers and character data, and the ability to specify decimal arithmetic operations.

There have been few developments in business application languages outside the development and evolution of COBOL. Therefore, this book includes only limited discussions of the structures in COBOL.

1.2.3 Artificial Intelligence

Artificial intelligence (AI) is a broad area of computer applications characterized by the use of symbolic rather than numeric computations. Symbolic computation means that symbols, consisting of names rather than numbers, are manipulated. Also, symbolic computation is more conveniently done with linked lists of data rather than arrays. This kind of programming sometimes requires more flexibility than other programming domains. For example, in some AI applications the ability to create and execute code segments during execution is convenient.

The first widely used programming language developed for AI applications was the functional language Lisp (McCarthy et al., 1965), which appeared in 1959. Most AI applications developed prior to 1990 were written in Lisp or one of its close relatives. During the early 1970s, however, an alternative approach to some of these applications appeared—logic programming using the Prolog (Clocksin and Mellish, 2013) language. More recently, some AI applications have been written in systems languages such as Python (Lutz, 2013). Scheme (Dybvig, 2011), a dialect of Lisp, and Prolog are introduced in Chapters 15 and 16, respectively.

1.2.4 Web Software

The World Wide Web is supported by an eclectic collection of languages, ranging from markup languages, such as HTML, which is not a programming

language, to general-purpose programming languages, such as Java. Because of the pervasive need for dynamic Web content, some computation capability is often included in the technology of content presentation. This functionality can be provided by embedding programming code in an HTML document. Such code is often in the form of a scripting language, such as JavaScript (Flanagan, 2011) or PHP (Tatroe et al., 2013). There are also some markup-like languages that have been extended to include constructs that control document processing, which are discussed in Section 1.5 and in Chapter 2.

1.3 Language Evaluation Criteria

As noted previously, the purpose of this book is to examine carefully the underlying concepts of the various constructs and capabilities of programming languages. We will also evaluate these features, focusing on their impact on the software development process, including maintenance. To do this, we need a set of evaluation criteria. Such a list of criteria is necessarily controversial, because it is difficult to get even two computer scientists to agree on the value of some given language characteristic relative to others. In spite of these differences, most would agree that the criteria discussed in the following subsections are important.

Some of the characteristics that influence three of the four most important of these criteria are shown in Table 1.1, and the criteria themselves are discussed in the following sections.2 Note that only the most important characteristics are included in the table, mirroring the discussion in the following subsections. One could probably make the case that if one considered less important characteristics, virtually all table positions could include “bullets.”

2. The fourth primary criterion is cost, which is not included in the table because it is only slightly related to the other criteria and the characteristics that influence them.

Table 1.1 Language evaluation criteria and the characteristics that affect them

	CRITERIA		
Characteristic	READABILITY	WRITABILITY	RELIABILITY
Simplicity	•	•	•
Orthogonality	•	•	•
Data types	•	•	•
Syntax design	•	•	•
Support for abstraction		•	•
Expressivity		•	•
Type checking			•
Exception handling			•
Restricted aliasing			•

Note that some of these characteristics are broad and somewhat vague, such as writability, whereas others are specific language constructs, such as exception handling. Furthermore, although the discussion might seem to imply that the criteria have equal importance, that implication is not intended, and it is clearly not the case.

1.3.1 Readability

One of the most important criteria for judging a programming language is the ease with which programs can be read and understood. Before 1970, software development was largely thought of in terms of writing code. The primary positive characteristic of programming languages was efficiency. Language constructs were designed more from the point of view of the computer than of the computer users. In the 1970s, however, the software life-cycle concept (Booch, 1987) was developed; coding was relegated to a much smaller role, and maintenance was recognized as a major part of the cycle, particularly in terms of cost. Because ease of maintenance is determined in large part by the readability of programs, readability became an important measure of the quality of programs and programming languages. This was an important juncture in the evolution of programming languages. There was a distinct crossover from a focus on machine orientation to a focus on human orientation.

Readability must be considered in the context of the problem domain. For example, if a program that describes a computation is written in a language not designed for such use, the program may be unnatural and convoluted, making it unusually difficult to read.

The following subsections describe characteristics that contribute to the readability of a programming language.

1.3.1.1 Overall Simplicity

The overall simplicity of a programming language strongly affects its readability. A language with a large number of basic constructs is more difficult to learn than one with a smaller number. Programmers who must use a large language often learn a subset of the language and ignore its other features. This learning pattern is sometimes used to excuse the large number of language constructs, but that argument is not valid. Readability problems occur whenever the program's author has learned a different subset from that subset with which the reader is familiar.

A second complicating characteristic of a programming language is **feature multiplicity**—that is, having more than one way to accomplish a particular operation. For example, in Java, a user can increment a simple integer variable in four different ways:

```
count = count + 1
count += 1
count++
++count
```

Although the last two statements have slightly different meanings from each other and from the others in some contexts, all of them have the same meaning when used as stand-alone expressions. These variations are discussed in Chapter 7.

A third potential problem is **operator overloading**, in which a single operator symbol has more than one meaning. Although this is often useful, it can lead to reduced readability if users are allowed to create their own

overloading and do not do it sensibly. For example, it is clearly acceptable to overload + to use it for both integer and floating-point addition. In fact, this overloading simplifies a language by reducing the number of operators. However, suppose the programmer defined + used between single-dimensioned array operands to mean the sum of all elements of both arrays. Because the usual meaning of vector addition is quite different from this, this unusual meaning could confuse both the author and the program's readers. An even more extreme example of program confusion would be a user defining + between two vector operands to mean the difference between their respective first elements. Operator overloading is further discussed in Chapter 7.

Simplicity in languages can, of course, be carried too far. For example, the form and meaning of most assembly language statements are models of simplicity, as you can see when you consider the statements that appear in the next section. This very simplicity, however, makes assembly language programs less readable. Because they lack more complex control statements, program structure is less obvious; because the statements are simple, far more of them are required than in equivalent programs in a high-level language. These same arguments apply to the less extreme case of high-level languages with inadequate control and data-structuring constructs.

1.3.1.2 Orthogonality

Orthogonality in a programming language means that a relatively small set of primitive constructs can be combined in a relatively small number of ways to build the control and data structures of the language. Furthermore, every possible combination of primitives is legal and meaningful. For example, consider data types. Suppose a language has four primitive data types (integer, float, double, and character) and two type operators (array and pointer). If the two type operators can be applied to themselves and the four primitive data types, a large number of data structures can be defined.

The meaning of an orthogonal language feature is independent of the context of its appearance in a program. (The word *orthogonal* comes from the mathematical concept of orthogonal vectors, which are independent of each

other.) Orthogonality follows from a symmetry of relationships among primitives. A lack of orthogonality leads to exceptions to the rules of the language. For example, in a programming language that supports pointers, it should be possible to define a pointer to point to any specific type defined in the language. However, if pointers are not allowed to point to arrays, many potentially useful user-defined data structures cannot be defined.

We can illustrate the use of orthogonality as a design concept by comparing one aspect of the assembly languages of the IBM mainframe computers and the VAX series of minicomputers. We consider a single simple situation: adding two 32-bit integer values that reside in either memory or registers and replacing one of the two values with the sum. The IBM mainframes have two instructions for this purpose, which have the forms

```
A Reg1, memory_cell
AR Reg1, Reg2
```

where `Reg1` and `Reg2` represent registers. The semantics of these are

```
Reg1 ← contents(Reg1) + contents(memory_cell)
Reg1 ← contents(Reg1) + contents(Reg2)
```

The VAX addition instruction for 32-bit integer values is

```
ADDL operand_1, operand_2
```

whose semantics is

```
operand_2 ← contents(operand_1) + contents(operand_2)
```

In this case, either operand can be a register or a memory cell.

The VAX instruction design is orthogonal in that a single instruction can use either registers or memory cells as its operands. There are two ways to specify operands, which can be combined in all possible ways. The IBM design is not orthogonal. Only two out of four operand combinations possibilities are legal, and the two require different instructions, `A` and `AR`. The IBM design is more restricted and therefore less writable. For example, you cannot add two values and store the sum in a memory location. Furthermore, the IBM design is more difficult to learn because of the

restrictions and the additional instruction.

Orthogonality is closely related to simplicity: The more orthogonal the design of a language, the fewer exceptions the language rules require. Fewer exceptions mean a higher degree of regularity in the design, which makes the language easier to learn, read, and understand. Anyone who has learned a significant part of the English language can testify to the difficulty of learning its many rule exceptions (for example, *i* before *e* except after *c*).

As examples of the lack of orthogonality in a high-level language, consider the following rules and exceptions in C. Although C has two kinds of structured data types, arrays and records (**`struct`**s), records can be returned from functions but arrays cannot. A member of a structure can be any data type except **`void`** or a structure of the same type. An array element can be any data type except **`void`** or a function. Parameters are passed by value, unless they are arrays, in which case they are, in effect, passed by reference (because the appearance of an array name without a subscript in a C program is interpreted to be the address of the array's first element).

As an example of context dependence, consider the C expression

```
a + b
```

This expression often means that the values of `a` and `b` are fetched and added together. However, if `a` happens to be a pointer and `b` is an integer, it affects the value of `b`. For example, if `a` points to a float value that occupies four bytes, then the value of `b` must be scaled—in this case multiplied by 4—before it is added to `a`. Therefore, the type of `a` affects the treatment of the value of `b`. The context of `b` affects its meaning.

Too much orthogonality can also cause problems. Perhaps the most orthogonal programming language is ALGOL 68 (van Wijngaarden et al., 1969). Every language construct in ALGOL 68 has a type, and there are no restrictions on those types. In addition, most constructs produce values. This combinational freedom allows extremely complex constructs. For example, a conditional can appear as the left side of an assignment, along with declarations and other assorted statements, as long as the result is an address. This extreme form of orthogonality leads to unnecessary complexity.

Furthermore, because languages require a large number of primitives, a high degree of orthogonality results in an explosion of combinations. So, even if the combinations are simple, their sheer numbers lead to complexity.

Simplicity in a language, therefore, is at least in part the result of a combination of a relatively small number of primitive constructs and a limited use of the concept of orthogonality.

Some believe that functional languages offer a good combination of simplicity and orthogonality. A functional language, such as Lisp, is one in which computations are made primarily by applying functions to given parameters. In contrast, in imperative languages such as C, C++, and Java, computations are usually specified with variables and assignment statements. Functional languages offer potentially the greatest overall simplicity, because they can accomplish everything with a single construct, the function call, which can be combined simply with other function calls. This simple elegance is the reason why some language researchers are attracted to functional languages as the primary alternative to complex nonfunctional languages such as Java. Other factors, the most important of which is probably efficiency, however, have prevented functional languages from becoming more widely used.

1.3.1.3 Data Types

The presence of adequate facilities for defining data types and data structures in a language is another significant aid to readability. For example, suppose a numeric type is used for an indicator flag because there is no Boolean type in the language. In such a language, for example, in the original version of C, we might have an assignment such as the following:

```
timeout = 1
```

The meaning of this statement is unclear, whereas in a language that includes Boolean types, we would have the following:

```
timeout = true
```

The meaning of this statement is perfectly clear.

1.3.1.4 Syntax Design

The syntax, or form, of the elements of a language has a significant effect on the readability of programs. Following are some examples of syntactic design choices that affect readability:

- Special words. Program appearance and thus program readability are strongly influenced by the forms of a language's special words (for example, **`while`**, **`class`**, and **`for`**). Especially important is the method of forming compound statements, or statement groups, primarily in control constructs. Some languages have used matching pairs of special words or symbols to form groups. C and its descendants use braces to specify compound statements. All of these languages have diminished readability because statement groups are always terminated in the same way, which makes it difficult to determine which group is being ended when an **`end`** or a right brace appears. Fortran 95 and Ada (ISO/IEC, 2014) make this clearer by using a distinct closing syntax for each type of statement group. For example, Ada uses **`end if`** to terminate a selection construct and **`end loop`** to terminate a loop construct. This is an example of the conflict between simplicity that results in fewer reserved words, as in Java, and the greater readability that can result from using more reserved words, as in Ada.

  Another important issue is whether the special words of a language can be used as names for program variables. If so, then the resulting programs can be very confusing. For example, in Fortran 95, special words, such as `Do` and `End`, are legal variable names, so the appearance of these words in a program may or may not connote something special.

- Form and meaning. Designing statements so that their appearance at least partially indicates their purpose is an obvious aid to readability. Semantics, or meaning, should follow directly from syntax, or form. In some cases, this principle is violated by two language constructs that are identical or similar in appearance but have different meanings,

depending perhaps on context. In C, for example, the meaning of the reserved word **`static`** depends on the context of its appearance. If used on the definition of a variable inside a function, it means the variable is created at compile time. If used on the definition of a variable that is outside all functions, then it means the variable is visible only in the file in which its definition appears; that is, it is not exported from that file.

One of the primary complaints about the shell commands of UNIX (Robbins, 2005) is that their appearance does no t always suggest their function. For example, the meaning of the UNIX command `grep` can be deciphered only through prior knowledge, or perhaps cleverness and familiarity with the UNIX editor, `ed`. The appearance of `grep` connotes nothing to UNIX beginners. (In `ed`, the command */regular_expression*/ searches for a substring that matches the regular expression. Preceding this with `g` makes it a global command, specifying that the scope of the search is the whole file being edited. Following the command with `p` specifies that lines with the matching substring are to be printed. So `g`*/regular_expression*/`p`, which can obviously be abbreviated as `grep`, prints all lines in a file that contain substrings that match its operand, which is a regular expression.)

1.3.2 Writability

Writability is a measure of how easily a language can be used to create programs for a chosen problem domain. Most of the language characteristics that affect readability also affect writability. This follows directly from the fact that the process of writing a program requires the programmer frequently to reread the part of the program that is already written.

As is the case with readability, writability must be considered in the context of the target problem domain of a language. It simply is not fair to compare the writability of two languages in the realm of a particular application when one was designed for that application and the other was not. For example, the writabilities of Visual BASIC (VB) (Halvorson, 2013) and C are dramatically different for creating a program that has a graphical user interface (GUI), for which VB is ideal. Their writabilities are also quite different for writing

systems programs, such as an operating system, for which C was designed.

The following subsections describe the most important characteristics influencing the writability of a language.

1.3.2.1 Simplicity and Orthogonality

If a language has a large number of different constructs, some programmers who use the language might not be familiar with all of them. This situation can lead to a misuse of some features and a disuse of others that may be either more elegant or more efficient, or both, than those that are used. It may even be possible, as noted by Hoare (1973), to use unknown features accidentally, with bizarre results. Therefore, a smaller number of primitive constructs and a consistent set of rules for combining them (that is, orthogonality) is much better than simply having a large number of primitives. A programmer can design a solution to a complex problem after learning only a simple set of primitive constructs.

On the other hand, too much orthogonality can be a detriment to writability. Errors in programs can go undetected when nearly any combination of primitives is legal. This can lead to code absurdities that cannot be discovered by the compiler.

1.3.2.2 Expressivity

Expressivity in a language can refer to several different characteristics. In a language such as APL (Gilman and Rose, 1983), it means that there are very powerful operators that allow a great deal of computation to be accomplished with a very small program. More commonly, it means that a language has relatively convenient, rather than cumbersome, ways of specifying computations. For example, in C, the notation `count++` is more convenient and shorter than `count = count + 1`. Also, the **`and then`** Boolean operator in Ada is a convenient way of specifying short-circuit evaluation of a Boolean expression. The inclusion of the **`for`** statement in Java makes writing

counting loops easier than with the use of **`while`**, which is also possible. All of these increase the writability of a language.

1.3.3 Reliability

A program is said to be reliable if it performs to its specifications under all conditions. The following subsections describe several language features that have a significant effect on the reliability of programs in a given language.

1.3.3.1 Type Checking

Type checking is simply testing for type errors in a given program, either by the compiler or during program execution. Type checking is an important factor in language reliability. Because run-time type checking is expensive, compile-time type checking is more desirable. Furthermore, the earlier errors in programs are detected, the less expensive it is to make the required repairs. The design of Java requires checks of the types of nearly all variables and expressions at compile time. This virtually eliminates type errors at run time in Java programs. Types and type checking are discussed in depth in Chapter 6.

One example of how failure to type check, at either compile time or run time, has led to countless program errors is the use of subprogram parameters in the original C language (Kernighan and Ritchie, 1978). In this language, the type of an actual parameter in a function call was not checked to determine whether its type matched that of the corresponding formal parameter in the function. An **`int`** type variable could be used as an actual parameter in a call to a function that expected a **`float`** type as its formal parameter, and neither the compiler nor the run-time system would detect the inconsistency. For example, because the bit string that represents the integer 23 is essentially unrelated to the bit string that represents a floating-point 23, if an integer 23 is sent to a function that expects a floating-point parameter, any uses of the parameter in the function will produce nonsense. Furthermore, such problems are often difficult to diagnose.3 The current version of C has eliminated this

problem by requiring all parameters to be type checked. Subprograms and parameter-passing techniques are discussed in Chapter 9.

3. In response to this and other similar problems, UNIX systems include a utility program named `lint` that checks C programs for such problems.

1.3.3.2 Exception Handling

The ability of a program to intercept run-time errors (as well as other unusual conditions detectable by the program), take corrective measures, and then continue is an obvious aid to reliability. This language facility is called **exception handling**. Ada, C++, Java, and C# include extensive capabilities for exception handling, but such facilities are practically nonexistent in some widely used languages, for example, C. Exception handling is discussed in Chapter 14.

1.3.3.3 Aliasing

Loosely defined, **aliasing** is having two or more distinct names in a program that can be used to access the same memory cell. It is now generally accepted that aliasing is a dangerous feature in a programming language. Most programming languages allow some kind of aliasing—for example, two pointers (or references) set to point to the same variable, which is possible in most languages. In such a program, the programmer must always remember that changing the value pointed to by one of the two changes the value referenced by the other. Some kinds of aliasing, as described in Chapters 5 and 9, can be prohibited by the design of a language.

In some languages, aliasing is used to overcome deficiencies in the language's data abstraction facilities. Other languages greatly restrict aliasing to increase their reliability.

1.3.3.4 Readability and Writability

Both readability and writability influence reliability. A program written in a language that does not support natural ways to express the required algorithms will necessarily use unnatural approaches. Unnatural approaches are less likely to be correct for all possible situations. The easier a program is to write, the more likely it is to be correct.

Readability affects reliability in both the writing and maintenance phases of the life cycle. Programs that are difficult to read are difficult both to write and to modify.

1.3.4 Cost

The total cost of a programming language is a function of many of its characteristics.

First, there is the cost of training programmers to use the language, which is a function of the simplicity and orthogonality of the language and the experience of the programmers. Although more powerful languages are not necessarily more difficult to learn, they often are.

Second, there is the cost of writing programs in the language. This is a function of the writability of the language, which depends in part on its closeness in purpose to the particular application. The original efforts to design and implement high-level languages were driven by the desire to lower the costs of creating software.

Both the cost of training programmers and the cost of writing programs in a language can be significantly reduced in a good programming environment. Programming environments are discussed in Section 1.8.

Third, the cost of executing programs written in a language is greatly influenced by that language's design. A language that requires many run-time type checks will prohibit fast code execution, regardless of the quality of the compiler. Although execution efficiency was the foremost concern in the design of early languages, it is now considered to be less important.

A simple trade-off can be made between compilation cost and execution speed of the compiled code. **Optimization** is the name given to the collection of techniques that compilers may use to decrease the size and/or increase the execution speed of the code they produce. If little or no optimization is done, compilation can be done much faster than if a significant effort is made to produce optimized code. The choice between the two alternatives is influenced by the environment in which the compiler will be used. In a laboratory for beginning programming students, who often compile their programs many times during development but use little execution time (their programs are small and they must execute correctly only once), little or no optimization should be done. In a production environment, where compiled programs are executed many times after development, it is better to pay the extra cost to optimize the code.

Fourth, there is the cost of poor reliability. If the software fails in a critical system, such as a nuclear power plant or an X-ray machine for medical use, the cost could be very high. The failures of noncritical systems can also be very expensive in terms of lost future business or lawsuits over defective software systems.

The final consideration is the cost of maintaining programs, which includes both corrections and modifications to add new functionality. The cost of software maintenance depends on a number of language characteristics, primarily readability. Because maintenance is often done by individuals other than the original author of the software, poor readability can make the task extremely challenging.

The importance of software maintainability cannot be overstated. It has been estimated that for large software systems with relatively long lifetimes, maintenance costs can be as high as two to four times as much as development costs (Sommerville, 2010).

Of all the contributors to language costs, three are most important: program development, maintenance, and reliability. Because these are functions of writability and readability, these two evaluation criteria are, in turn, the most important.

Of course, a number of other criteria could be used for evaluating

programming languages. One example is **portability**, or the ease with which programs can be moved from one implementation to another. Portability is most strongly influenced by the degree of standardization of the language. Some languages are not standardized at all, making programs in these languages very difficult to move from one implementation to another. This problem is alleviated in some cases by the fact that implementations for some languages now have single sources. Standardization is a time-consuming and difficult process. A committee began work on producing a standard version of C++ in 1989. It was approved in 1998.

Generality (the applicability to a wide range of applications) and **well--definedness** (the completeness and precision of the language's official defining document) are two other criteria.

Most criteria, particularly readability, writability, and reliability, are neither precisely defined nor accurately measurable. Nevertheless, they are useful concepts and they provide valuable insight into the design and evaluation of programming languages.

A final note on evaluation criteria: language design criteria are weighed differently from different perspectives. Language implementors are concerned primarily with the difficulty of implementing the constructs and features of the language. Language users are worried about writability first and readability later. Language designers are likely to emphasize elegance and the ability to attract widespread use. These characteristics often conflict with one another.

1.4 Influences on Language Design

In addition to those factors described in Section 1.3, several other factors influence the basic design of programming languages. The most important of these are computer architecture and programming design methodologies.

1.4.1 Computer Architecture

The basic architecture of computers has had a profound effect on language design. Most of the popular languages of the past 60 years have been designed around the prevalent computer architecture, called the **von Neumann architecture**, after one of its originators, John von Neumann (pronounced “von Noyman”). These languages are called **imperative** languages. In a von Neumann computer, both data and programs are stored in the same memory. The central processing unit (CPU), which executes instructions, is separate from the memory. Therefore, instructions and data must be transmitted, or piped, from memory to the CPU. Results of operations in the CPU must be moved back to memory. Nearly all digital computers built since the 1940s have been based on the von Neumann architecture. The overall structure of a von Neumann computer is shown in Figure 1.1.

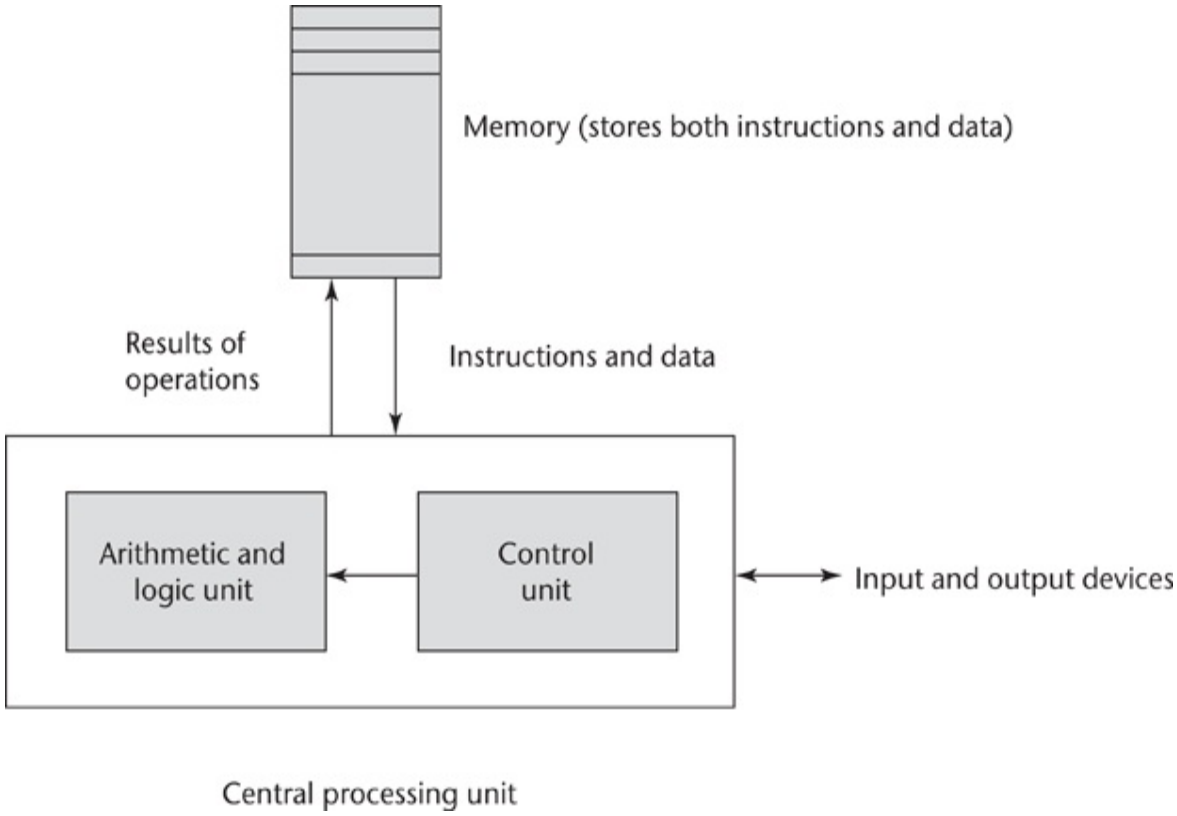

Figure 1.1 The von Neumann computer architecture

Figure 1.1 Full Alternative Text

Because of the von Neumann architecture, the central features of imperative languages are variables, which model the memory cells; assignment statements, which are based on the piping operation; and the iterative form of repetition, which is the most efficient way to implement repetition on this architecture. Operands in expressions are piped from memory to the CPU, and the result of evaluating the expression is piped back to the memory cell represented by the left side of the assignment. Iteration is fast on von Neumann computers because instructions are stored in adjacent cells of memory and repeating the execution of a section of code requires only a branch instruction. This efficiency discourages the use of recursion for repetition, although recursion is sometimes more natural.

The execution of a machine code program on a von Neumann architecture computer occurs in a process called the **fetch-execute cycle**. As stated earlier, programs reside in memory but are executed in the CPU. Each instruction to be executed must be moved from memory to the processor. The address of the next instruction to be executed is maintained in a register called the **program counter**. The fetch-execute cycle can be simply described by the following algorithm:

- initialize the program counter
- **`repeat`** forever
- fetch the instruction pointed to by the program counter
- increment the program counter to point at the next instruction
- decode the instruction
- execute the instruction
- **`end repeat`**

The “decode the instruction” step in the algorithm means the instruction is examined to determine what action it specifies. Program execution terminates when a stop instruction is encountered, although on an actual computer a stop instruction is rarely executed. Rather, control transfers from the operating system to a user program for its execution and then back to the operating system when the user program execution is complete. In a computer system in which more than one user program may be in memory at a given time, this process is far more complex.

As stated earlier, a functional, or applicative, language is one in which the primary means of computation is applying functions to given parameters. Programming can be done in a functional language without the kind of variables that are used in imperative languages, without assignment statements, and without iteration. Although many computer scientists have expounded on the myriad benefits of functional languages, such as Scheme, it is unlikely that they will displace the imperative languages until a non–von

Neumann computer is designed that allows efficient execution of programs in functional languages. Among those who have bemoaned this fact, perhaps the most eloquent was John Backus (1978), the principal designer of the original version of Fortran.

In spite of the fact that the structure of imperative programming languages is modeled on a machine architecture, rather than on the abilities and inclinations of the users of programming languages, some believe that using imperative languages is somehow more natural than using a functional language. So, these people believe that even if functional programs were as efficient as imperative programs, the use of imperative programming languages would still dominate.

1.4.2 Programming Design Methodologies

The late 1960s and early 1970s brought an intense analysis, begun in large part by the structured-programming movement, of both the software development process and programming language design.

An important reason for this research was the shift in the major cost of computing from hardware to software, as hardware costs decreased and programmer costs increased. Increases in programmer productivity were relatively small. In addition, progressively larger and more complex problems were being solved by computers. Rather than simply solving sets of equations to simulate satellite tracks, as in the early 1960s, programs were being written for large and complex tasks, such as controlling large petroleum-refining facilities and providing worldwide airline reservation systems.

The new software development methodologies that emerged as a result of the research of the 1970s were called top-down design and stepwise refinement. The primary programming language deficiencies that were discovered were incompleteness of type checking and inadequacy of control statements (requiring the extensive use of gotos).

In the late 1970s, a shift from procedure-oriented to data-oriented program design methodologies began. Simply put, data-oriented methods emphasize data design, focusing on the use of abstract data types to solve problems.

For data abstraction to be used effectively in software system design, it must be supported by the languages used for implementation. The first language to provide even limited support for data abstraction was SIMULA 67 (Birtwistle et al., 1973), although that language certainly was not propelled to popularity because of it. The benefits of data abstraction were not widely recognized until the early 1970s. However, most languages designed since the late 1970s support data abstraction, which is discussed in detail in Chapter 11.

The latest step in the evolution of data-oriented software development, which began in the early 1980s, is object-oriented design. Object-oriented methodology begins with data abstraction, which encapsulates processing with data objects and controls access to data, and adds inheritance and dynamic method binding. Inheritance is a powerful concept that greatly enhances the potential reuse of existing software, thereby providing the possibility of significant increases in software development productivity. This is an important factor in the increase in popularity of object-oriented languages. Dynamic (run-time) method binding allows more flexible use of inheritance.

Object-oriented programming developed along with a language that supported its concepts: Smalltalk (Goldberg and Robson, 1989). Although Smalltalk never became as widely used as many other languages, support for object-oriented programming is now part of most popular imperative languages, including Java, C++, and C#. Object-oriented concepts have also found their way into functional programming in CLOS (Bobrow et al., 1988) and F# (Syme et al., 2010), as well as logic programming in Prolog++ (Moss, 1994). Language support for object-oriented programming is discussed in detail in Chapter 12.

Procedure-oriented programming is, in a sense, the opposite of data-oriented programming. Although data-oriented methods now dominate software development, procedure-oriented methods have not been abandoned. On the contrary, in recent years, a good deal of research has occurred in procedure-oriented programming, especially in the area of concurrency. These research

efforts brought with them the need for language facilities for creating and controlling concurrent program units. Java and C# include such capabilities. Concurrency is discussed in detail in Chapter 13.

All of these evolutionary steps in software development methodologies led to new language constructs to support them.

1.5 Language Categories

Programming languages are often categorized into four bins: imperative, functional, logic, and object oriented. However, we do not consider languages that support object-oriented programming to form a separate category of languages. We have described how the most popular languages that support object-oriented programming grew out of imperative languages. Although the object-oriented software development paradigm differs significantly from the procedure-oriented paradigm usually used with imperative languages, the extensions to an imperative language required to support object-oriented programming are not intensive. For example, the expressions, assignment statements, and control statements of C and Java are nearly identical. (On the other hand, the arrays, subprograms, and semantics of Java are very different from those of C.) Similar statements can be made for functional languages that support object-oriented programming.

Some authors refer to scripting languages as a separate category of programming languages. However, languages in this category are bound together more by their implementation method, partial or full interpretation, than by a common language design. The languages that are typically called scripting languages, among them Perl, JavaScript, and Ruby (Flanagan and Matsumoto, 2008), are imperative languages in every sense.

A logic programming language is an example of a rule-based language. In an imperative language, an algorithm is specified in great detail, and the specific order of execution of the instructions or statements must be included. In a rule-based language, however, rules are specified in no particular order, and the language implementation system must choose an order in which the rules are used to produce the desired result. This approach to software development is radically different from those used with the other two categories of languages and clearly requires a completely different kind of language. Prolog, the most commonly used logic programming language, and logic programming are discussed in Chapter 16.

In recent years, a new category of languages has emerged, the

markup/programming hybrid languages. Markup languages are not programming languages. For instance, HTML, the most widely used markup language, is used to specify the layout of information in Web documents. However, some programming capability has crept into some extensions to HTML and XML. Among these are the Java Server Pages Standard Tag Library (JSTL) and eXtensible Stylesheet Language Transformations (XSLT). Both of these are briefly introduced in Chapter 2. Those languages cannot be compared to any of the complete programming languages and therefore will not be discussed after Chapter 2.

1.6 Language Design Trade-Offs

The programming language evaluation criteria described in Section 1.3 - provide a framework for language design. Unfortunately, that framework is self-contradictory. In his insightful paper on language design, Hoare (1973) stated that "there are so many important but conflicting criteria, that their reconciliation and satisfaction is a major engineering task."

Two criteria that conflict are reliability and cost of execution. For example, the Java language definition demands that all references to array elements be checked to ensure that the index or indices are in their legal ranges. This step adds a great deal to the cost of execution of Java programs that contain large numbers of references to array elements. C does not require index range checking, so C programs execute faster than semantically equivalent Java programs, although Java programs are more reliable. The designers of Java traded execution efficiency for reliability.

As another example of conflicting criteria that leads directly to design trade-offs, consider the case of APL. APL includes a powerful set of operators for array operands. Because of the large number of operators, a significant number of new symbols had to be included in APL to represent the operators. Also, many APL operators can be used in a single, long, complex expression. One result of this high degree of expressivity is that, for applications involving many array operations, APL is very writable. Indeed, a huge amount of computation can be specified in a very small program. Another result is that APL programs have very poor readability. A compact and concise expression has a certain mathematical beauty but it is difficult for anyone other than the programmer to understand. Well-known author Daniel McCracken (1970) once noted that it took him four hours to read and understand a four-line APL program. The designer of APL traded readability for writability.

The conflict between writability and reliability is a common one in language design. The pointers of C++ can be manipulated in a variety of ways, which supports highly flexible addressing of data. Because of the potential

reliability problems with pointers, they are not included in Java.

Examples of conflicts among language design (and evaluation) criteria abound; some are subtle, others are obvious. It is therefore clear that the task of choosing constructs and features when designing a programming language requires many compromises and trade-offs.

1.7 Implementation Methods

As described in Section 1.4.1, two of the primary components of a computer are its internal memory and its processor. The internal memory is used to store programs and data. The processor is a collection of circuits that provides a realization of a set of primitive operations, or machine instructions, such as those for arithmetic and logic operations. In most computers, some of these instructions, which are sometimes called macroinstructions, are actually implemented with a set of instructions called microinstructions, which are defined at an even lower level. Because microinstructions are never seen by software, they will not be discussed further here.

The machine language of the computer is its set of instructions. In the absence of other supporting software, its own machine language is the only language that most hardware computers "understand." Theoretically, a computer could be designed and built with a particular high-level language as its machine language, but it would be very complex and expensive. Furthermore, it would be highly inflexible, because it would be difficult (but not impossible) to use it with other high-level languages. The more practical machine design choice implements in hardware a very low-level language that provides the most commonly needed primitive operations and requires system software to create an interface to programs in higher-level languages.

A language implementation system cannot be the only software on a computer. Also required is a large collection of programs, called the operating system, which supplies higher-level primitives than those of the machine language. These primitives provide system resource management, input and output operations, a file management system, text and/or program editors, and a variety of other commonly needed functions. Because language implementation systems need many of the operating system facilities, they interface with the operating system rather than directly with the processor (in machine language).

The operating system and language implementations are layered over the

machine language interface of a computer. These layers can be thought of as virtual computers, providing interfaces to the user at higher levels. For example, an operating system and a C compiler provide a virtual C computer. With other compilers, a machine can become other kinds of virtual computers. Most computer systems provide several different virtual computers. User programs form another layer over the top of the layer of virtual computers. The layered view of a computer is shown in Figure 1.2.

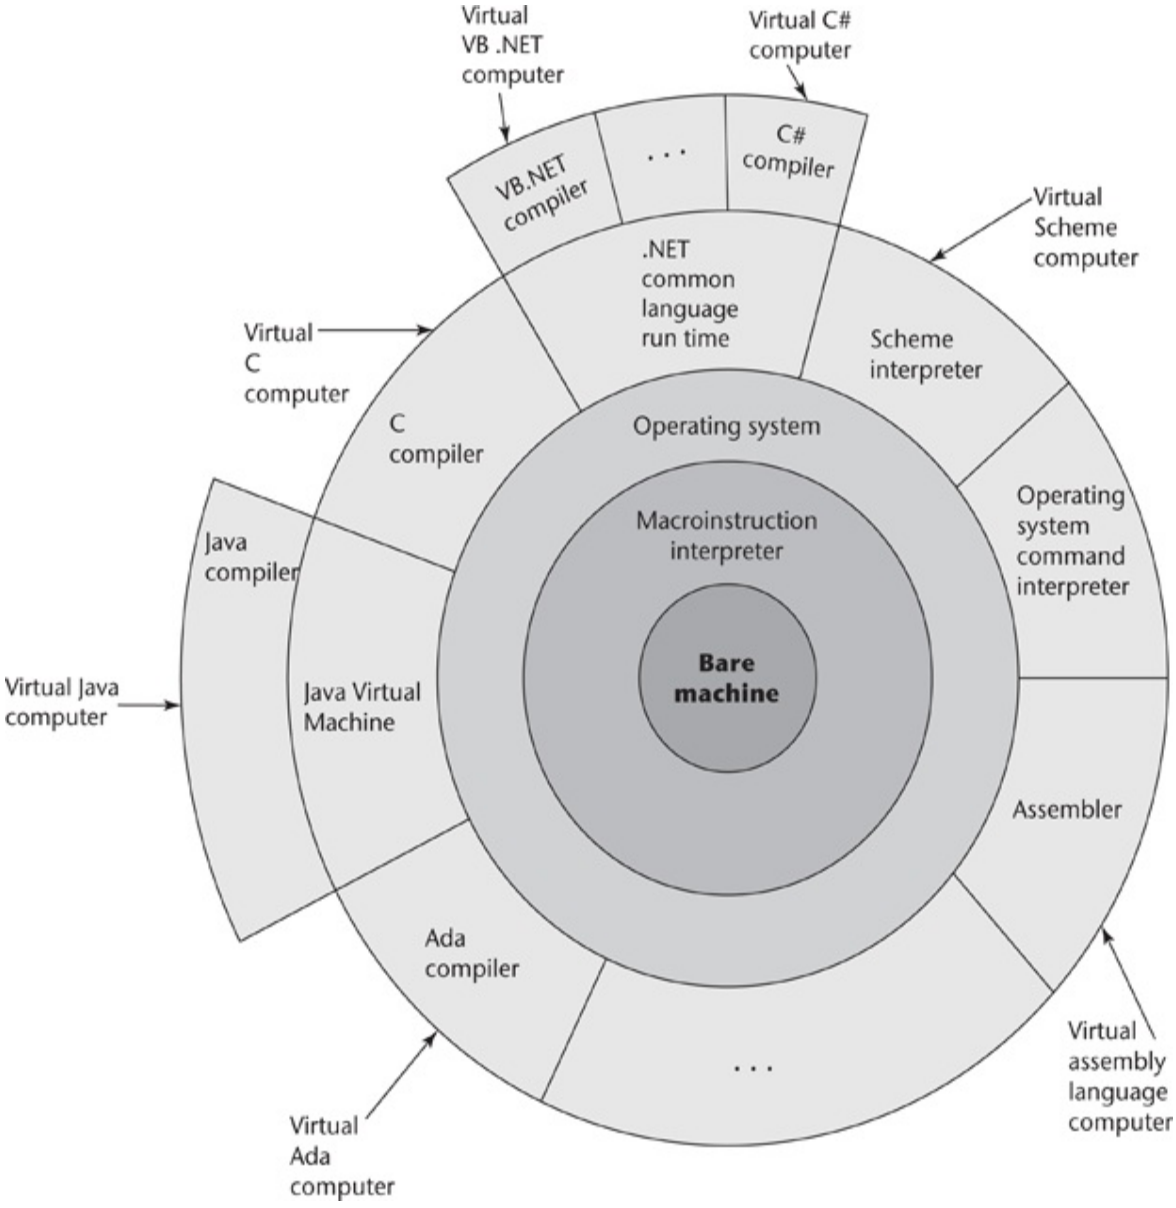

Figure 1.2 Layered interface of

virtual computers, provided by a typical computer system

Figure 1.2 Full Alternative Text

The implementation systems of the first high-level programming languages, constructed in the late 1950s, were among the most complex software systems of that time. In the 1960s, intensive research efforts were made to understand and formalize the process of constructing these high-level language implementations. The greatest success of those efforts was in the area of syntax analysis, primarily because that part of the implementation process is an application of parts of automata theory and formal language theory that were then well understood.

1.7.1 Compilation

Programming languages can be implemented by any of three general methods. At one extreme, programs can be translated into machine language, which can be executed directly on the computer. This method is called a **compiler implementation** and has the advantage of very fast program execution, once the translation process is complete. Most production implementations of languages, such as C, COBOL, and C++, are by compilers.

The language that a compiler translates is called the **source language**. The process of compilation and program execution takes place in several phases, the most important of which are shown in Figure 1.3.

Figure 1.3 Full Alternative Text

The lexical analyzer gathers the characters of the source program into lexical units. The lexical units of a program are identifiers, special words, operators, and punctuation symbols. The lexical analyzer ignores comments in the source program because the compiler has no use for them.

The syntax analyzer takes the lexical units from the lexical analyzer and uses them to construct hierarchical structures called **parse trees**. These parse trees represent the syntactic structure of the program. In many cases, no actual parse tree structure is constructed; rather, the information that would be required to build a tree is generated and used directly. Both lexical units and parse trees are discussed further in Chapter 3. Lexical analysis and syntax analysis, or parsing, are discussed in Chapter 4.

The intermediate code generator produces a program in a different language, at an intermediate level between the source program and the final output of the compiler: the machine language program.4 Intermediate languages sometimes look very much like assembly languages, and in fact, sometimes are actual assembly languages. In other cases, the intermediate code is at a level somewhat higher than an assembly language. The semantic analyzer is an integral part of the intermediate code generator. The semantic analyzer checks for errors, such as type errors, that are difficult, if not impossible, to detect during syntax analysis.

4. Note that the words *program* and *code* are often used interchangeably.

Optimization, which improves programs (usually in their intermediate code version) by making them smaller or faster or both. Because many kinds of optimization are difficult to do on machine language, most optimization is done on the intermediate code.

The code generator translates the optimized intermediate code version of the

program into an equivalent machine language program.

The symbol table serves as a database for the compilation process. The primary contents of the symbol table are the type and attribute information of each user-defined name in the program. This information is placed in the symbol table by the lexical and syntax analyzers and is used by the semantic analyzer and the code generator.

As stated previously, although the machine language generated by a compiler can be executed directly on the hardware, it must nearly always be run along with some other code. Most user programs also require programs from the operating system. Among the most common of these are programs for input and output. The compiler builds calls to required system programs when they are needed by the user program. Before the machine language programs produced by a compiler can be executed, the required programs from the operating system must be found and linked to the user program. The linking operation connects the user program to the system programs by placing the addresses of the entry points of the system programs in the calls to them in the user program. The user and system code together are sometimes called a **load module**, or **executable image**. The process of collecting system programs and linking them to user programs is called **linking and loading**, or sometimes just **linking**. It is accomplished by a systems program called a **linker**.

In addition to systems programs, user programs must often be linked to previously compiled programs that reside in libraries. So the linker not only links a given program to system programs, but also it may link it to other user or system-supplied programs.

The speed of the connection between a computer’s memory and its processor often determines the speed of the computer, because instructions often can be executed faster than they can be moved to the processor for execution. This connection is called the **von Neumann bottleneck**; it is the primary limiting factor in the speed of von Neumann architecture computers. The von Neumann bottleneck has been one of the primary motivations for the research and development of parallel computers.

1.7.2 Pure Interpretation

Pure interpretation lies at the opposite end (from compilation) among implementation methods. With this approach, programs are interpreted by another program called an interpreter, with no translation whatever. The interpreter program acts as a software simulation of a machine whose fetch-execute cycle deals with high-level language program statements rather than machine instructions. This software simulation obviously provides a virtual machine for the language.

Pure interpretation has the advantage of allowing easy implementation of many source-level debugging operations, because all run-time error messages can refer to source-level units. For example, if an array index is found to be out of range, the error message can easily indicate the source line of the error and the name of the array. On the other hand, this method has the serious disadvantage that execution is 10 to 100 times slower than in compiled systems. The primary source of this slowness is the decoding of the high-level language statements, which are far more complex than machine language instructions (although there may be fewer statements than instructions in equivalent machine code). Furthermore, regardless of how many times a statement is executed, it must be decoded every time. Therefore, statement decoding, rather than the connection between the processor and memory, is the bottleneck of a pure interpreter.

Another disadvantage of pure interpretation is that it often requires more space. In addition to the source program, the symbol table must be present during interpretation. Furthermore, the source program may be stored in a form designed for easy access and modification rather than one that provides for minimal size.

Although some simple early languages of the 1960s (APL, SNOBOL (Griswold et al., 1971), and Lisp) were purely interpreted, by the 1980s, the approach was rarely used on high-level languages. However, in recent years, pure interpretation has made a significant comeback with some Web scripting languages, such as JavaScript and PHP, which are now widely used. The process of pure interpretation is shown in Figure 1.4.

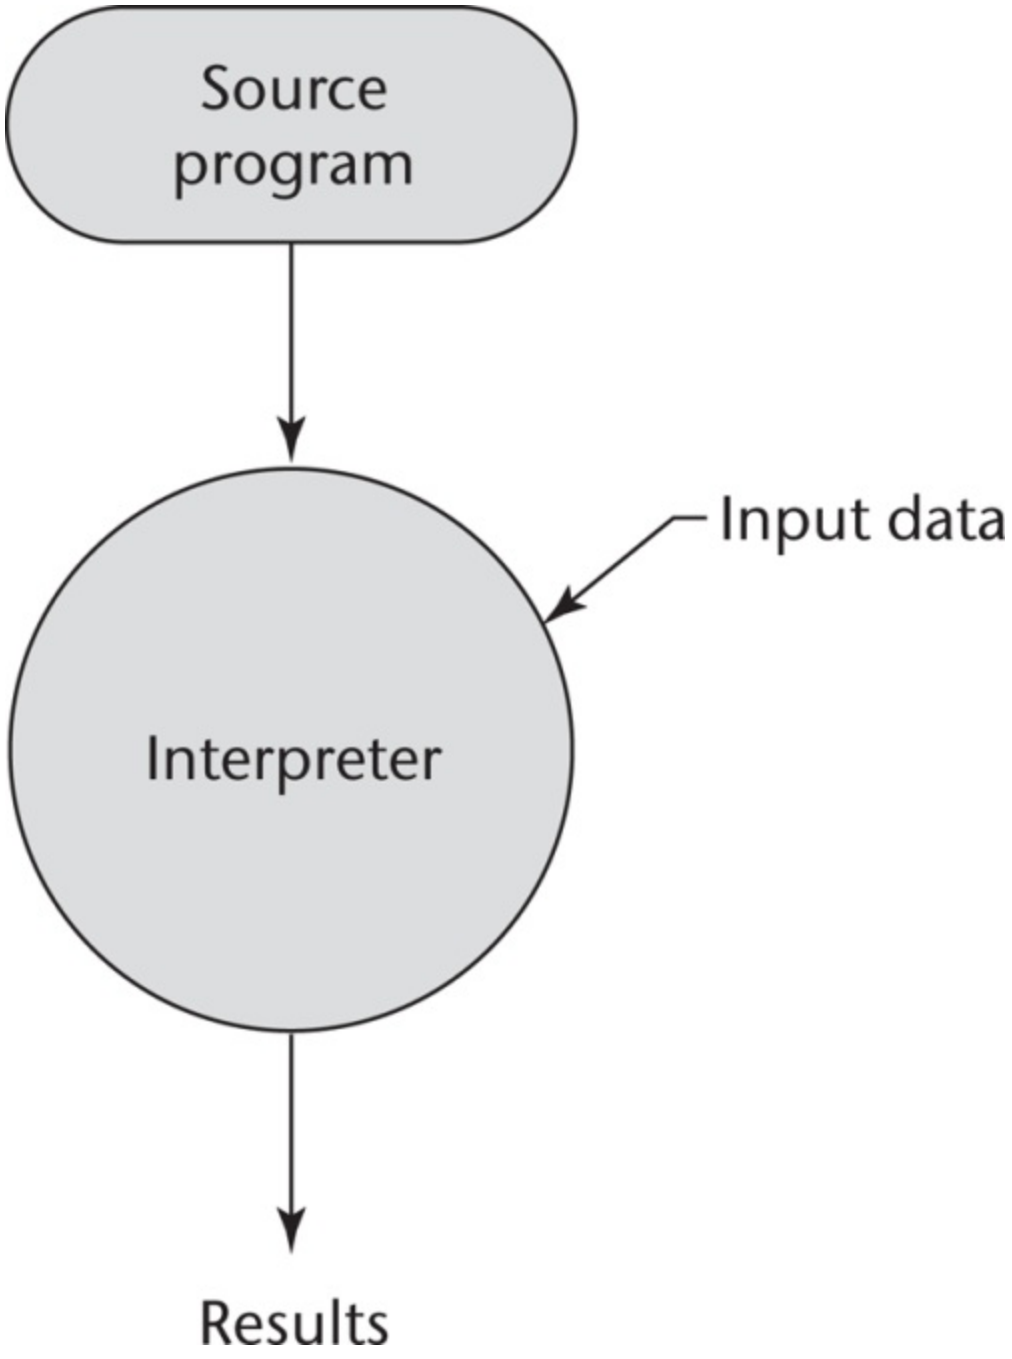

Figure 1.4 Pure interpretation

1.7.3 Hybrid Implementation

Systems

Some language implementation systems are a compromise between compilers and pure interpreters; they translate high-level language programs to an intermediate language designed to allow easy interpretation. This method is faster than pure interpretation because the source language statements are decoded only once. Such implementations are called **hybrid implementation systems**.

The process used in a hybrid implementation system is shown in Figure 1.5. Instead of translating intermediate language code to machine code, it simply interprets the intermediate code.

Figure 1.5 Hybrid implementation system

Figure 1.5 Full Alternative Text

Perl is implemented with a hybrid system. Perl programs are partially - compiled to detect errors before interpretation and to simplify the interpreter.

Initial implementations of Java were all hybrid. Its intermediate form, called **byte code**, provides portability to any machine that has a byte code interpreter and an associated run-time system. Together, these are called the Java Virtual Machine. There are now systems that translate Java byte code into machine code for faster execution.

A Just-in-Time (JIT) implementation system initially translates programs to an intermediate language. Then, during execution, it compiles intermediate language methods into machine code when they are called. The machine code version is kept for subsequent calls. JIT systems now are widely used for Java programs. Also, the .NET languages are all implemented with a JIT system.

Sometimes an implementor may provide both compiled and interpreted implementations for a language. In these cases, the interpreter is used to develop and debug programs. Then, after a (relatively) bug-free state is reached, the programs are compiled to increase their execution speed.

1.7.4 Preprocessors

A **preprocessor** is a program that processes a program just before the program is compiled. Preprocessor instructions are embedded in programs. The preprocessor is essentially a macro expander. Preprocessor instructions are commonly used to specify that the code from another file is to be included. For example, the C preprocessor instruction

```
#include "myLib.h"
```

causes the preprocessor to copy the contents of `myLib.h` into the program at the position of the `#include`.

Other preprocessor instructions are used to define symbols to represent expressions. For example, one could use

```
#define max(A, B) ((A) > (B) ? (A) : (B))
```

to determine the largest of two given expressions. For example, the expression

```
x = max(2 * y, z / 1.73);
```

would be expanded by the preprocessor to

```
x = ((2 * y) > (z / 1.73) ? (2 * y) : (z / 1.73);
```

Notice that this is one of those cases where expression side effects can cause trouble. For example, if either of the expressions given to the `max` macro have side effects—such as `z++`—it could cause a problem. Because one of the two expression parameters is evaluated twice, this could result in `z` being -incremented twice by the code produced by the macro expansion.

1.8 Programming Environments

A programming environment is the collection of tools used in the development of software. This collection may consist of only a file system, a text editor, a linker, and a compiler. Or it may include a large collection of integrated tools, each accessed through a uniform user interface. In the latter case, the process of the development and maintenance of software is greatly enhanced. Therefore, the characteristics of a programming language are not the only measure of the software development capability of a system. We now briefly describe several programming environments.

UNIX is an older programming environment, first distributed in the middle 1970s, built around a portable multiprogramming operating system. It provides a wide array of powerful support tools for software production and maintenance in a variety of languages. In the past, the most important feature absent from UNIX was a uniform interface among its tools. This made it more difficult to learn and to use. However, UNIX is now often used through a GUI that runs on top of UNIX. Examples of UNIX GUIs are the Solaris Common Desktop Environment (CDE), GNOME, and KDE. These GUIs make the interface to UNIX appear similar to that of Windows and Macintosh systems.

Borland JBuilder is a programming environment that provides an integrated compiler, editor, debugger, and file system for Java development, where all four are accessed through a graphical interface. JBuilder is a complex and powerful system for creating Java software.

Microsoft Visual Studio .NET is a relatively recent step in the evolution of software development environments. It is a large and elaborate collection of software development tools, all used through a windowed interface. This system can be used to develop software in any one of the five .NET languages: C#, Visual Basic.NET, JScript (Microsoft’s version of JavaScript), F# (a functional language), and C++/CLI.

NetBeans is a development environment that is primarily used for Java

application development but also supports JavaScript, Ruby, and PHP. Both Visual Studio and NetBeans are more than development environments—they are also frameworks, which means they actually provide common parts of the code of the application.

SUMMARY

The study of programming languages is valuable for some important reasons: It increases our capacity to use different constructs in writing programs, enables us to choose languages for projects more intelligently, and makes learning new languages easier.

Computers are used in a wide variety of problem-solving domains. The design and evaluation of a particular programming language is highly - dependent on the domain in which it is to be used.

Among the most important criteria for evaluating languages are readability, writability, reliability, and overall cost. These will be the basis on which we examine and judge the various language features discussed in the remainder of the book.

The major influences on language design have been machine architecture and software design methodologies.

Designing a programming language is primarily an engineering feat, in which a long list of trade-offs must be made among features, constructs, and capabilities.

The major methods of implementing programming languages are compilation, pure interpretation, and hybrid implementation.

Programming environments have become important parts of software development systems, in which the language is just one of the components.

REVIEW QUESTIONS

1. Why is it useful for a programmer to have some background in language design, even though he or she may never actually design a programming language?

2. How can knowledge of programming language characteristics benefit the whole computing community?

3. What programming language has dominated scientific computing over the past 60 years?

4. What programming language has dominated business applications over the past 60 years?

5. What programming language has dominated artificial intelligence over the past 60 years?

6. In what language is most of UNIX written?

7. What is the disadvantage of having too many features in a language?

8. How can user-defined operator overloading harm the readability of a program?

9. What is one example of a lack of orthogonality in the design of C?

10. What language used orthogonality as a primary design criterion?

11. What primitive control statement is used to build more complicated control statements in languages that lack them?

12. What does it mean for a program to be reliable?

13. Why is type checking the parameters of a subprogram important?

14. What is aliasing?

15. What is exception handling?

16. Why is readability important to writability?

17. How is the cost of compilers for a given language related to the design of that language?

18. What have been the strongest influences on programming language design over the past 60 years?

19. What is the name of the category of programming languages whose structure is dictated by the von Neumann computer architecture?

20. What two programming language deficiencies were discovered as a result of the research in software development in the 1970s?

21. What are the three fundamental features of an object-oriented programming language?

22. What language was the first to support the three fundamental features of object-oriented programming?

23. What is an example of two language design criteria that are in direct conflict with each other?

24. What are the three general methods of implementing a programming language?

25. Which produces faster program execution, a compiler or a pure interpreter?

26. What role does the symbol table play in a compiler?

27. What does a linker do?

28. Why is the von Neumann bottleneck important?

29. What are the advantages in implementing a language with a pure interpreter?

PROBLEM SET

1. Do you believe our capacity for abstract thought is influenced by our language skills? Support your opinion.

2. What are some features of specific programming languages you know whose rationales are a mystery to you?

3. What arguments can you make for the idea of a single language for all programming domains?

4. What arguments can you make against the idea of a single language for all programming domains?

5. Name and explain another criterion by which languages can be judged (in addition to those discussed in this chapter).

6. What common programming language statement, in your opinion, is most detrimental to readability?

7. Java uses a right brace to mark the end of all compound statements. What are the arguments for and against this design?

8. Many languages distinguish between uppercase and lowercase letters in user-defined names. What are the pros and cons of this design decision?

9. Explain the different aspects of the cost of a programming language.

10. What are the arguments for writing efficient programs even though hardware is relatively inexpensive?

11. Describe some design trade-offs between efficiency and safety in some language you know.

12. In your opinion, what major features would a perfect programming language include?

13. Was the first high-level programming language you learned implemented with a pure interpreter, a hybrid implementation system, or a compiler? (You may have to research this.)

14. Describe the advantages and disadvantages of some programming environment you have used.

15. How do type declaration statements for simple variables affect the readability of a language, considering that some languages do not require them?

16. Write an evaluation of some programming language you know, using the criteria described in this chapter.

17. Some programming languages—for example, Pascal—have used the semicolon to separate statements, while Java uses it to terminate statements. Which of these, in your opinion, is most natural and least likely to result in syntax errors? Support your answer.

18. Many contemporary languages allow two kinds of comments: one in which delimiters are used on both ends (multiple-line comments), and one in which a delimiter marks only the beginning of the comment (one-line comments). Discuss the advantages and disadvantages of each of these with respect to our criteria.

2 Evolution of the Major Programming Languages

This chapter describes the development of a collection of programming - languages. It explores the environment in which each was designed and focuses on the contributions of the language and the motivation for its development. Overall language descriptions are not included; rather, we discuss only some of the new features introduced by each language. Of particular interest are the features that most influenced subsequent languages or the field of computer science.

This chapter does not include an in-depth discussion of any language feature or concept; that is left for later chapters. Brief, informal explanations of features will suffice for our trek through the development of these languages.

We discuss a wide variety of languages and language concepts that will not be familiar to many readers. These topics are described in detail only in later chapters. Those who find this unsettling may prefer to delay reading this chapter until the rest of the book has been studied.

The choice as to which languages to discuss here was subjective, and some - readers will unhappily note the absence of one or more of their favorites. However, to keep this historical coverage to a reasonable size, it was necessary to leave out some languages that some regard highly. The choices were based on our estimate of each language’s importance to language development and the computing world as a whole. We also include brief discussions of some other languages that are referenced later in the book.

The organization of this chapter is as follows: The initial versions of languages generally are discussed in chronological order. However, subsequent versions of languages appear with their initial version, rather than in later sections. For example, Fortran 2003 is discussed in the section with Fortran I (1956). Also, in some cases, languages of secondary importance that are related to a language that has its own section appear in that section.

This chapter includes listings of 14 complete example programs, each in a different language. These programs are not described in this chapter; they are meant to illustrate the appearance of programs in these languages. Readers familiar with any of the common imperative languages should be able to read and understand most of the code in these programs, except those in Lisp, COBOL, and Smalltalk. (A Scheme function similar to the Lisp example is discussed in Chapter 15.) The same problem is solved by the Fortran, ALGOL 60, PL/I, Basic, Pascal, C, Perl, Ada, Java, JavaScript, and C# programs. Note that most of the contemporary languages in this list support dynamic arrays, but because of the simplicity of the example problem, we did not use them in the example programs. Also, in the Fortran 95 program, we avoided using the features that could have avoided the use of loops altogether, in part to keep the program simple and readable and in part just to illustrate the basic loop structure of the language.

Figure 2.1 Genealogy of common high-level programming languages

Figure 2.1 Full Alternative Text

2.1 Zuse’s Plankalkül

The first programming language discussed in this chapter is highly unusual in several respects. For one thing, it was never implemented. Furthermore, although developed in 1945, its description was not published until 1972. Because so few people were familiar with the language, some of its capabilities did not appear in other languages until 15 years after its development.

2.1.1 Historical Background

Between 1936 and 1945, German scientist Konrad Zuse (pronounced “Tsoo-zuh”) built a series of complex and sophisticated computers from electromechanical relays. By early 1945, Allied bombing had destroyed all but one of his latest models, the Z4, so he moved to a remote Bavarian village, Hinterstein, and his research group members went their separate ways.

Working alone, Zuse embarked on an effort to develop a language for expressing computations for the Z4, a project he had begun in 1943 as a proposal for his Ph.D. dissertation. He named this language Plankalkül, which means *program calculus*. In a lengthy manuscript dated 1945 but not published until 1972 (Zuse, 1972), Zuse defined Plankalkül and wrote algorithms in the language to solve a wide variety of problems.

2.1.2 Language Overview

Plankalkül was remarkably complete, with some of its most advanced features in the area of data structures. The simplest data type in Plankalkül was the single bit. Integer and floating-point numeric types were built from the bit type. The floating-point type used twos-complement notation and the “hidden bit” scheme currently used to avoid storing the most significant bit of

the normalized fraction part of a floating-point value.

In addition to the usual scalar types, Plankalkül included arrays and records (called *structs* in the C-based languages). The records could include nested records.

Although the language had no explicit goto, it did include an iterative statement similar to the Ada `for`. It also had the command `Fin` with a superscript that specified an exit out of a given number of iteration loop nestings or to the beginning of a new iteration cycle. Plankalkül included a selection statement, but it did not allow an `else` clause.

One of the most interesting features of Zuse's programs was the inclusion of mathematical expressions showing the current relationships between program variables. These expressions stated what would be true during execution at the points in the code where they appeared. These are very similar to the assertions of Java and in those in axiomatic semantics, which is discussed in Chapter 3.

Zuse's manuscript contained programs of far greater complexity than any written prior to 1945. Included were programs to sort arrays of numbers; test the connectivity of a given graph; carry out integer and floating-point operations, including square root; and perform syntax analysis on logic formulas that had parentheses and operators in six different levels of precedence. Perhaps most remarkable were his 49 pages of algorithms for playing chess, a game in which he was not an expert.

If a computer scientist had found Zuse's description of Plankalkül in the early 1950s, the single aspect of the language that would have hindered its implementation as defined would have been the notation. Each statement consisted of either two or three lines of code. The first line was most like the statements of current languages. The second line, which was optional, contained the subscripts of the array references in the first line. The same method of indicating subscripts was used by Charles Babbage in programs for his Analytical Engine in the middle of the nineteenth century. The last line of each Plankalkül statement contained the type names for the variables mentioned in the first line. This notation is quite intimidating when first seen.

The following example assignment statement, which assigns the value of the expression `A[4} + 1` to `A[5]`, illustrates this notation. The row labeled `V` is for subscripts, and the row labeled `S` is for the data types. In this example, `1.n` means an integer of *n* bits:

```
  | A + 1 =>  A
V | 4         5
S | 1.n       1.n
```

We can only speculate on the direction that programming language design might have taken if Zuse's work had been widely known in 1945 or even 1950. It is also interesting to consider how his work might have been different had he done it in a peaceful environment surrounded by other scientists, rather than in Germany in 1945 in virtual isolation.

2.2 Pseudocodes

First, note that the word *pseudocode* is used here in a different sense than its contemporary meaning. We call the languages discussed in this section pseudocodes because that's what they were named at the time they were developed and used (the late 1940s and early 1950s). However, they are clearly not pseudocodes in the contemporary sense.

The computers that became available in the late 1940s and early 1950s were far less usable than those of today. In addition to being slow, unreliable, expensive, and having extremely small memories, the machines of that time were difficult to program because of the lack of supporting software.

There were no high-level programming languages or even assembly languages, so programming was done in machine code, which is both tedious and error prone. Among its problems is the use of numeric codes for specifying instructions. For example, an ADD instruction might be specified by the code 14 rather than a connotative textual name, even if only a single letter. This makes programs very difficult to read. A more serious problem is absolute addressing, which makes program modification tedious and error prone. For example, suppose we have a machine language program stored in memory. Many of the instructions in such a program refer to other locations within the program, usually to reference data or to indicate the targets of branch instructions. Inserting an instruction at any position in the program other than at the end invalidates the correctness of all instructions that refer to addresses beyond the insertion point, because those addresses must be increased to make room for the new instruction. To make the addition correctly, all instructions that refer to addresses that follow the addition must be found and modified. A similar problem occurs with deletion of an instruction. In this case, however, machine languages often include a "no operation" instruction that can replace deleted instructions, thereby avoiding the problem.

These are standard problems with all machine languages and were the primary motivations for inventing assemblers and assembly languages. In

addition, most programming problems of that time were numerical and required floating-point arithmetic operations and indexing of some sort to allow the convenient use of arrays. Neither of these capabilities, however, was included in the architecture of the computers of the late 1940s and early 1950s. These deficiencies naturally led to the development of somewhat higher-level languages.

2.2.1 Short Code

The first of these new languages, named Short Code, was developed by John Mauchly in 1949 for the BINAC computer, which was one of the first successful stored-program electronic computers. Short Code was later transferred to a UNIVAC I computer (the first commercial electronic computer sold in the United States) and, for several years, was one of the primary means of programming those machines. Although little is known of the original Short Code because its complete description was never published, a programming manual for the UNIVAC I version did survive (Remington-Rand, 1952). It is safe to assume that the two versions were very similar.

The words of the UNIVAC I's memory had 72 bits, grouped as 12 six-bit bytes. Short Code consisted of coded versions of mathematical expressions that were to be evaluated. The codes were byte-pair values, and many equations could be coded in a word. The following operation codes were included:

```
01 -    06 abs value      1n (n+2)nd power
02 )    07 +              2n (n+2)nd root
03 =    08 pause          4n if <= n
04 /    09 (              58 print and tab
```

Variables were named with byte-pair codes, as were locations to be used as constants. For example, `X0` and `Y0` could be variables. The statement

```
X0 = SQRT(ABS(Y0))
```

would be coded in a word as `00 X0 03 20 06 Y0`. The initial `00` was used as

padding to fill the word. Interestingly, there was no multiplication code; multiplication was indicated by simply placing the two operands next to each other, as in algebra.

Short Code was not translated to machine code; rather, it was implemented with a pure interpreter. At the time, this process was called *automatic programming*. It clearly simplified the programming process, but at the expense of execution time. Short Code interpretation was approximately 50 times slower than machine code.

2.2.2 Speedcoding

In other places, interpretive systems were being developed that extended machine languages to include floating-point operations. The Speedcoding system developed by John Backus for the IBM 701 is an example of such a system (Backus, 1954). The Speedcoding interpreter effectively converted the 701 to a virtual three-address floating-point calculator. The system included pseudoinstructions for the four arithmetic operations on floating-point data, as well as operations such as square root, sine, arc tangent, exponent, and logarithm. Conditional and unconditional branches and input/output conversions were also part of the virtual architecture. To get an idea of the limitations of such systems, consider that the remaining usable memory after loading the interpreter was only 700 words and that the add instruction took 4.2 milliseconds to execute. On the other hand, Speedcoding included the novel facility of automatically incrementing address registers. This facility did not appear in hardware until the UNIVAC 1107 computers of 1962. Because of such features, matrix multiplication could be done in 12 Speedcoding instructions. Backus claimed that problems that could take two weeks to program in machine code could be programmed in a few hours using Speedcoding.

2.2.3 The UNIVAC “Compiling” System

Between 1951 and 1953, a team led by Grace Hopper at UNIVAC developed a series of “compiling” systems named A-0, A-1, and A-2 that expanded a pseudocode into machine code subprograms in the same way as macros are expanded into assembly language. The pseudocode source for these “compilers” was still quite primitive, although even this was a great improvement over machine code because it made source programs much shorter. Wilkes (1952) independently suggested a similar process.

2.2.4 Related Work

Other means of easing the task of programming were being developed at about the same time. At Cambridge University, David J. Wheeler (1950) developed a method of using blocks of relocatable addresses to solve, at least partially, the problem of absolute addressing, and later, Maurice V. Wilkes (also at Cambridge) extended the idea to design an assembly program that could combine chosen subroutines and allocate storage (Wilkes et al., 1951, 1957). This was indeed an important and fundamental advance.

We should also mention that assembly languages, which are quite different from the pseudocodes discussed, evolved during the early 1950s. However, they had little impact on the design of high-level languages.

2.3 The IBM 704 and Fortran

Certainly one of the greatest single advances in computing came with the introduction of the IBM 704 in 1954, in large measure because its capabilities prompted the development of Fortran. One could argue that if it had not been IBM with the 704 and Fortran, it would soon thereafter have been some other organization with a similar computer and related high-level language. However, IBM was the first with both the foresight and the resources to undertake these developments.

2.3.1 Historical Background

One of the primary reasons why the slowness of interpretive systems was tolerated from the late 1940s to the mid-1950s was the lack of floating-point hardware in the available computers. All floating-point operations had to be simulated in software, a very time-consuming process. Because so much processor time was spent in software floating-point processing, the overhead of interpretation and the simulation of indexing were relatively insignificant. As long as floating-point had to be done by software, interpretation was an acceptable expense. However, many programmers of that time never used interpretive systems, preferring the efficiency of hand-coded machine (or assembly) language. The announcement of the IBM 704 system, with both indexing and floating-point instructions in hardware, heralded the end of the interpretive era, at least for scientific computation. The inclusion of floating-point hardware removed the hiding place for the cost of interpretation.

Although Fortran is often credited with being the first compiled high-level language, the question of who deserves credit for implementing the first such language is somewhat open. Knuth and Pardo (1977) give the credit to Alick E. Glennie for his Autocode compiler for the Manchester Mark I computer. Glennie developed the compiler at Fort Halstead, Royal Armaments Research Establishment, in England. The compiler was operational by September 1952. However, according to John Backus (Wexelblat, 1981, p. 26),

Glennie's Autocode was so low level and machine oriented that it should not be considered a compiled system. Backus gives the credit to Laning and Zierler at the Massachusetts Institute of Technology.

The Laning and Zierler system (Laning and Zierler, 1954) was the first algebraic translation system to be implemented. By algebraic, we mean that it translated arithmetic expressions, used separately coded subprograms to compute transcendental functions (e.g., sine and logarithm), and included arrays. The system was implemented on the MIT Whirlwind computer, in experimental prototype form, in the summer of 1952 and in a more usable form by May 1953. The translator generated a subroutine call to code each formula, or expression, in the program. The source language was easy to read, and the only actual machine instructions included were for branching. Although this work preceded the work on Fortran, it never escaped MIT.

In spite of these earlier works, the first widely accepted compiled high-level language was Fortran. The following subsections chronicle this important development.

2.3.2 Design Process

Even before the 704 system was announced in May 1954, plans were begun for Fortran. By November 1954, John Backus and his group at IBM had produced the report titled "The IBM Mathematical FORmula TRANslating System: FORTRAN" (IBM, 1954). This document described the first version of Fortran, which we refer to as Fortran 0, prior to its implementation. It also boldly stated that Fortran would provide the efficiency of hand-coded programs and the ease of programming of the interpretive pseudocode systems. In another burst of optimism, the document stated that Fortran would eliminate coding errors and the debugging process. Based on this premise, the first Fortran compiler included little syntax error checking.

The environment in which Fortran was developed was as follows: (1) Computers had small memories and were slow and relatively unreliable; (2) the primary use of computers was for scientific computations; (3) there were no existing efficient and effective ways to program computers; and (4)

because of the high cost of computers compared to the cost of programmers, speed of the generated object code was the primary goal of the first Fortran compilers. The characteristics of the early versions of Fortran follow directly from this environment.

2.3.3 Fortran I Overview

Fortran 0 was modified during the implementation period, which began in January 1955 and continued until the release of the compiler in April 1957. The implemented language, which we call Fortran I, is described in the first Fortran *Programmer's Reference Manual*, published in October 1956 (IBM, 1956). Fortran I included input/output formatting, variable names of up to six characters (it had been just two in Fortran 0), user-defined subroutines, although they could not be separately compiled, the `If` selection statement, and the `Do` loop statement.

All of Fortran I's control statements were based on 704 instructions. It is not clear whether the 704 designers dictated the control statement design of Fortran I or whether the designers of Fortran I suggested these instructions to the 704 designers.

There were no data-typing statements in the Fortran I language. Variables whose names began with `I`, `J`, `K`, `L`, `M`, and `N` were implicitly integer type, and all others were implicitly floating-point. The choice of the letters for this convention was based on the fact that at that time scientists and engineers used letters as variable subscripts, usually *i*, *j*, and *k*. In a gesture of generosity, Fortran's designers threw in the three additional letters.

The most audacious claim made by the Fortran development group during the design of the language was that the machine code produced by the compiler would be about half as efficient as what could be produced by hand.1 This, more than anything else, made skeptics of potential users and prevented a great deal of interest in Fortran before its actual release. To almost everyone's surprise, however, the Fortran development group nearly achieved its goal in efficiency. The largest part of the 18 worker-years of effort used to construct the first compiler had been spent on optimization, and

the results were remarkably effective.

1. In fact, the Fortran team believed that the code generated by their compiler could be no less than half as fast as handwritten machine code, or the language would not be adopted by users.

The early success of Fortran is shown by the results of a survey made in April 1958. At that time, roughly half of the code being written for 704s was being written in Fortran, in spite of the skepticism of most of the programming world only a year earlier.

2.3.4 Fortran II

The Fortran II compiler was distributed in the spring of 1958. It fixed many of the bugs in the Fortran I compilation system and added some significant features to the language, the most important being the independent compilation of subroutines. Without independent compilation, any change in a program required that the entire program be recompiled. Fortran I's lack of independent-compilation capability, coupled with the poor reliability of the 704, placed a practical restriction on the length of programs to about 300 to 400 lines (Wexelblat, 1981, p. 68). Longer programs had a poor chance of being compiled completely before a machine failure occurred. The capability of including precompiled machine language versions of subprograms shortened the compilation process considerably and made it practical to develop much larger programs.

2.3.5 Fortrans IV, 77, 90, 95, 2003, and 2008

A Fortran III was developed, but it was never widely distributed. Fortran IV, however, became one of the most widely used programming languages of its time. It evolved over the period 1960 to 1962 and was standardized as Fortran 66 (ANSI, 1966), although that name was rarely used. Fortran IV was

an improvement over Fortran II in many ways. Among its most important additions were explicit type declarations for variables, a logical `If` construct, and the capability of passing subprograms as parameters to other subprograms.

Fortran IV was replaced by Fortran 77, which became the new standard in 1978 (ANSI, 1978a). Fortran 77 retained most of the features of Fortran IV and added character string handling, logical loop control statements, and an `If` with an optional `Else` clause.

Fortran 90 (ANSI, 1992) was dramatically different from Fortran 77. The most significant additions were dynamic arrays, records, pointers, a multiple selection statement, and modules. In addition, Fortran 90 subprograms could be recursively called.

A new concept that was included in the Fortran 90 definition was that of removing some language features from earlier versions. While Fortran 90 included all of the features of Fortran 77, the language definition included a list of constructs that were recommended for removal in the next version of the language.

Fortran 90 included two simple syntactic changes that altered the appearance of both programs and the literature describing the language. First, the required fixed format of code, which required the use of specific character positions for specific parts of statements, was dropped. For example, statement labels could appear only in the first five positions and statements could not begin before the seventh position. This rigid formatting of code was designed around the use of punch cards. The second change was that the official spelling of FORTRAN became Fortran. This change was accompanied by the change in convention of using all uppercase letters for keywords and identifiers in Fortran programs. The new convention was that only the first letter of keywords and identifiers would be uppercase.

Fortran 95 (INCITS/ISO/IEC, 1997) continued the evolution of the language, but only a few changes were made. Among other things, a new iteration construct, `Forall`, was added to ease the task of parallelizing Fortran programs.

Fortran 2003 (Metcalf et al., 2004) added support for object-oriented programming, parameterized derived types, procedure pointers, and interoperability with the C programming language.

The latest version of Fortran, Fortran 2008 (ISO/IEC 1539-1, 2010), added support for blocks to define local scopes, co-arrays, which provide a parallel execution model, and the `DO CONCURRENT` construct, to specify loops without interdependencies. A new version, Fortran 2015, is under development and is scheduled for release in 2018.

2.3.6 Evaluation

The original Fortran design team thought of language design only as a necessary prelude to the critical task of designing the translator. Furthermore, it never occurred to them that Fortran would be used on computers not manufactured by IBM. However, they were forced to consider building Fortran compilers for other IBM machines only because the successor to the 704, the 709, was announced before the 704 Fortran compiler was released. The effect that Fortran has had on the use of computers, along with the fact that all subsequent programming languages owe a debt to Fortran, is indeed impressive in light of the modest goals of its designers.

One of the features of Fortran I, and all of its successors before 90, that allows highly optimizing compilers was that the types and storage for all - variables are fixed before run time. No new variables or space could be allocated during execution. This was a sacrifice of flexibility to simplicity and efficiency. It eliminated the possibility of recursive subprograms and made it difficult to implement data structures that grow or change shape dynamically. Of course, the kinds of programs that were being built at the time of the development of the early versions of Fortran were primarily numerical in nature and were simple in comparison with more recent software projects. Therefore, the sacrifice was not a great one.

The overall success of Fortran is difficult to overstate: It dramatically changed the way computers are used. This is, of course, in large part due to its being the first widely used high-level language. In comparison with

concepts and languages developed later, early versions of Fortran suffer in a variety of ways, as should be expected. After all, it would not be fair to compare the performance and comfort of a 1910 Model T Ford with the performance and comfort of a 2017 Ford Mustang. Nevertheless, in spite of the inadequacies of Fortran, the momentum of the huge investment in Fortran software, among other factors, has kept it in use for 60 years.

Alan Perlis, one of the designers of ALGOL 60, said of Fortran in 1978, “Fortran is the *lingua franca* of the computing world. It is the language of the streets in the best sense of the word, not in the prostitutional sense of the word. And it has survived and will survive because it has turned out to be a remarkably useful part of a very vital commerce” (Wexelblat, 1981, p. 161).

The following is an example of a Fortran 95 program:

```
! Fortran 95 Example program
!  Input:   An integer, List_Len, where List_Len is less
!           than 100, followed by List_Len-Integer values
!  Output:  The number of input values that are greater
!           than the average of all input values
Implicit none
Integer Dimension(99) :: Int_List
Integer :: List_Len, Counter, Sum, Average, Result
Result= 0
Sum = 0
Read *, List_Len
If ((List_Len > 0) .AND. (List_Len < 100)) Then
! Read input data into an array and compute its sum
   Do Counter = 1, List_Len
      Read *, Int_List(Counter)
      Sum = Sum + Int_List(Counter)
   End Do
! Compute the average
   Average = Sum / List_Len
! Count the values that are greater than the average
   Do Counter = 1, List_Len
      If (Int_List(Counter) > Average) Then
          Result = Result + 1
      End If
   End Do
! Print the result
   Print *, 'Number of values > Average is:', Result
Else
   Print *, 'Error - list length value is not legal'
```

```
End If
End Program Example
```

2.4 Functional Programming: Lisp

The first functional programming language was invented to provide language features for list processing, the need for which grew out of the first applications in the area of artificial intelligence (AI).

2.4.1 The Beginnings of Artificial Intelligence (AI) and List Processing

Interest in AI appeared in the mid-1950s in a number of places. Some of this interest grew out of linguistics, some from psychology, and some from mathematics. Linguists were concerned with natural language processing. - Psychologists were interested in modeling human information storage and retrieval, as well as other fundamental processes of the brain. Mathematicians were interested in mechanizing certain intelligent processes, such as theorem proving. All of these investigations arrived at the same conclusion: Some method must be developed to allow computers to process symbolic data in linked lists. At the time, nearly all computation was on numeric data in arrays.

The concept of list processing was developed by Allen Newell, J. C. Shaw, and Herbert Simon at the RAND Corporation. It was first published in a classic paper that describes one of the first AI programs, the Logic Theorist,[2] and a language in which it could be implemented (Newell and Simon, 1956). The language, named IPL-I (Information Processing Language I), was never implemented. The next version, IPL-II, was implemented on a RAND Johnniac computer. Development of IPL continued until 1960, when the description of IPL-V was published (Newell and Tonge, 1960). The low level of the IPL languages prevented their widespread use. They were actually assembly languages for a hypothetical computer, implemented with an interpreter, in which list-processing instructions were included. Another factor that kept the IPL languages from becoming popular was their

implementation on the obscure Johnniac machine.

2. Logic Theorist discovered proofs for theorems in propositional calculus.

The contributions of the IPL languages were in their list design and their demonstration that list processing was feasible and useful.

IBM became interested in AI in the mid-1950s and chose theorem proving as a demonstration area. At the time, the Fortran project was still underway. The high cost of the Fortran I compiler convinced IBM that their list processing should be attached to Fortran, rather than in the form of a new language. Thus, the Fortran list processing language (FLPL) was designed and implemented as an extension to Fortran. FLPL was used to construct a theorem prover for plane geometry, which was then considered the easiest area for mechanical theorem proving.

2.4.2 Lisp Design Process

John McCarthy of MIT took a summer position at the IBM Information Research Department in 1958. His goal for the summer was to investigate symbolic computations and to develop a set of requirements for doing such computations. As a pilot example problem area, he chose differentiation of algebraic expressions. From this study came a list of language requirements. Among them were the control flow methods of mathematical functions: recursion and conditional expressions. The only available high-level language of the time, Fortran I, had neither of these.

Another requirement that grew from the symbolic-differentiation investigation was the need for dynamically allocated linked lists and some kind of implicit deallocation of abandoned lists. McCarthy simply would not allow his elegant algorithm for differentiation to be cluttered with explicit deallocation statements.

Because FLPL did not support recursion, conditional expressions, dynamic storage allocation, or implicit deallocation, it was clear to McCarthy that a new language was needed.

When McCarthy returned to MIT in the fall of 1958, he and Marvin Minsky formed the MIT AI Project, with funding from the Research Laboratory for Electronics at MIT. The first important effort of the project was to produce a software system for list processing. It was to be used initially to implement a program proposed by McCarthy called the Advice Taker.3 This application became the impetus for the development of the list-processing language Lisp. The first version of Lisp is sometimes called “pure Lisp” because it is a purely functional language. In the following section, we describe the development of pure Lisp.

3. Advice Taker represented information with sentences written in a formal language and used a logical inferencing process to decide what to do.

2.4.3 Language Overview

2.4.3.1 Data Structures

Pure Lisp has only two kinds of data structures: atoms and lists. Atoms are either symbols, which have the form of identifiers, or numeric literals. The concept of storing symbolic information in linked lists is natural and was used in IPL-II. Such structures allow insertions and deletions at any point, operations that were then thought to be a necessary part of list processing. It was eventually determined, however, that Lisp programs rarely require these operations.

Lists are specified by delimiting their elements with parentheses. Simple lists, in which elements are restricted to atoms, have the form

```
(A B C D)
```

Nested list structures are also specified by parentheses. For example, the list

```
(A (B C) D (E (F G)))
```

is composed of four elements. The first is the atom `A`; the second is the sublist `(B C)`; the third is the atom `D`; the fourth is the sublist `(E (F G))`, which has

as its second element the sublist `(F G)`.

Internally, lists are stored as single-linked list structures, in which each node has two pointers and represents a list element. A node containing an atom has its first pointer pointing to some representation of the atom, such as its symbol or numeric value, or a pointer to a sublist. A node for a sublist element has its first pointer pointing to the first node of the sublist. In both cases, the second pointer of a node points to the next element of the list. A list is referenced by a pointer to its first element.

The internal representations of the two lists shown earlier are depicted in Figure 2.2. Note that the elements of a list are shown horizontally. The last element of a list has no successor, so its link is `NIL`, which is represented in Figure 2.2 as a diagonal line in the element. Sublists are shown with the same structure.

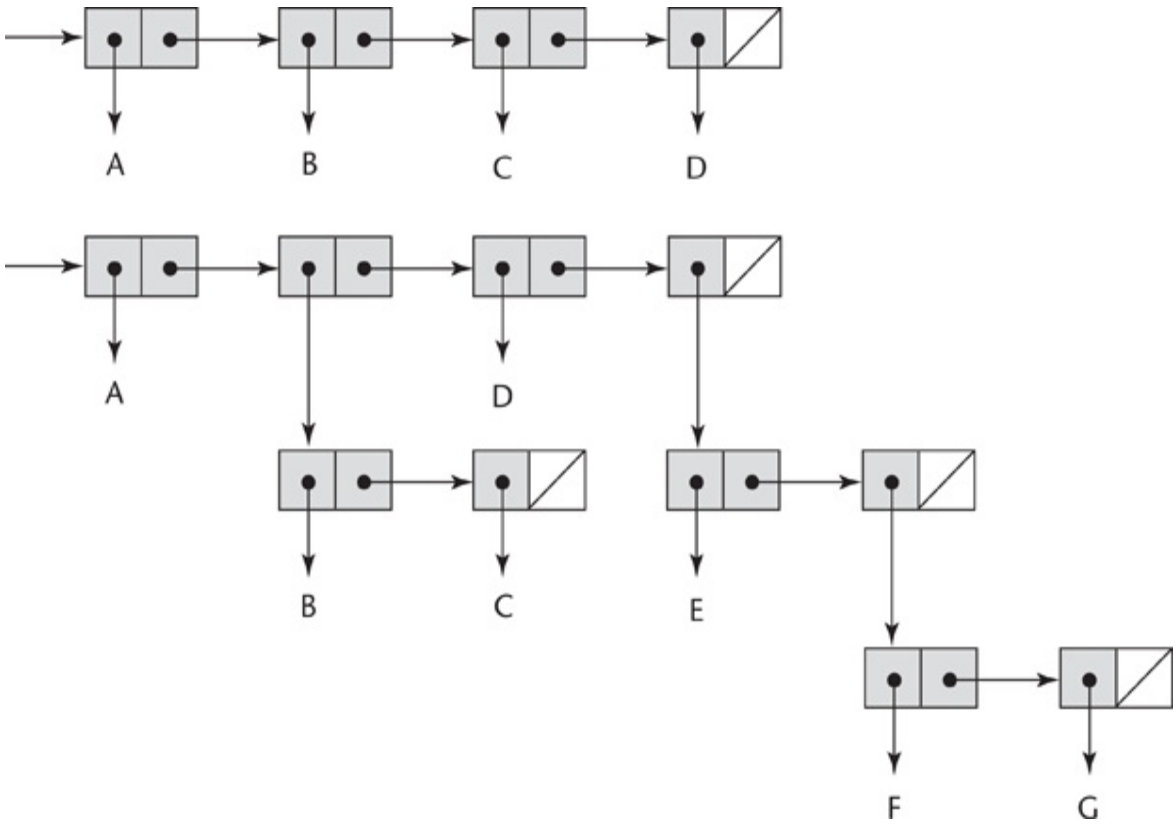

Figure 2.2 Internal

representation of two Lisp lists

Figure 2.2 Full Alternative Text

2.4.3.2 Processes in Functional Programming

Lisp was designed as a functional programming language. All computation in a purely functional program is accomplished by applying functions to arguments. Neither the assignment statements nor the variables that abound in imperative language programs are necessary in functional language programs. Furthermore, repetitive processes can be specified with recursive function calls, making iteration (loops) unnecessary. These basic concepts of functional programming make it significantly different from programming in an imperative language.

2.4.3.3 The Syntax of Lisp

Lisp is very different from the imperative languages, both because it is a functional programming language and because the appearance of Lisp programs is so different from those in languages like Java or C++. For example, the syntax of Java is a complicated mixture of English and algebra, while Lisp's syntax is a model of simplicity. Program code and data have exactly the same form: parenthesized lists. Consider again the list

```
(A B C D)
```

When interpreted as data, it is a list of four elements. When viewed as code, it is the application of the function named `A` to the three parameters `B`, `C`, and `D`.

2.4.4 Evaluation

Lisp completely dominated AI applications for a quarter century. Much of the cause of Lisp's reputation for being highly inefficient has been eliminated. Many contemporary implementations are compiled, and the resulting code is much faster than running the source code on an interpreter. In addition to its success in AI, Lisp pioneered functional programming, which has proven to be a lively area of research in programming languages. As stated in Chapter 1, many programming language researchers believe functional programming is a much better approach to software development than procedural programming using imperative languages.

The following is an example of a Lisp program:

```
; Lisp Example function
; The following code defines a Lisp predicate function
; that takes two lists as arguments and returns True
; if the two lists are equal, and NIL (false) otherwise
  (DEFUN equal_lists (lis1 lis2)
   (COND
     ((ATOM lis1) (EQ lis1 lis2))
     ((ATOM lis2) NIL)
     ((equal_lists (CAR lis1) (CAR lis2))
                 (equal_lists (CDR lis1) (CDR lis2)))
     (T NIL)
   )
)
```

2.4.5 Two Descendants of Lisp

Two dialects of Lisp are now widely used, Scheme and Common Lisp. These are briefly discussed in the following subsections.

2.4.5.1 Scheme

The Scheme language emerged from MIT in the mid-1970s. It is characterized by its small size, its exclusive use of static scoping (discussed in Chapter 5), and its treatment of functions as first-class entities. As first-class entities, Scheme functions can be assigned to variables, passed as

parameters, and returned as the values of function applications. They can also be the elements of lists. Early versions of Lisp did not provide all of these capabilities, nor did they use static scoping.

As a small language with simple syntax and semantics, Scheme is well suited to educational applications, such as courses in functional programming and general introductions to programming. Scheme is described in some detail in Chapter 15.

2.4.5.2 Common Lisp

During the 1970s and early 1980s, a large number of different dialects of Lisp were developed and used. This led to the familiar problem of lack of portability among programs written in the various dialects. Common Lisp - (Graham, 1996) was created in an effort to rectify this situation. Common Lisp was designed by combining the features of several dialects of Lisp developed in the early 1980s, including Scheme, into a single language. Being such an amalgam, Common Lisp is a relatively large and complex language. Its basis, however, is pure Lisp, so its syntax, primitive functions, and fundamental nature come from that language.

Recognizing the flexibility provided by dynamic scoping as well as the simplicity of static scoping, Common Lisp allows both. The default scoping for variables is static, but by declaring a variable to be **`special`**, that variable becomes dynamically scoped.

Common Lisp has a large number of data types and structures, including records, arrays, complex numbers, and character strings. It also has a form of packages for modularizing collections of functions and data providing access control.

Common Lisp is further described in Chapter 15.

2.4.6 Related Languages

ML (*Meta**L**anguage*; Ullman, 1998) was originally designed in the 1980s by Robin Milner at the University of Edinburgh as a metalanguage for a program verification system named Logic for Computable Functions (LCF; Milner et al., 1997). ML is primarily a functional language, but it also supports imperative programming. Unlike Lisp and Scheme, the type of every variable and expression in ML can be determined at compile time. Types are associated with objects rather than names. Types of names and expressions are inferred from their context.

Unlike Lisp and Scheme, ML does not use the parenthesized functional syntax that originated with lambda expressions. Rather, the syntax of ML resembles that of the imperative languages, such as Java and C++.

Miranda was developed by David Turner (1986) at the University of Kent in Canterbury, England, in the early 1980s. Miranda is based partly on the languages ML, SASL, and KRC. Haskell (Hudak and Fasel, 1992) is based in large part on Miranda. Like Miranda, it is a purely functional language, having no variables and no assignment statement. Another distinguishing characteristic of Haskell is its use of lazy evaluation. This means that no expression is evaluated until its value is required. This leads to some surprising capabilities in the language.

Caml (Cousineau et al., 1998) and its dialect that supports object-oriented programming, OCaml (Smith, 2006), descended from ML and Haskell. Finally, F# is a relatively new typed language based directly on OCaml. F# (Syme et al., 2010) is a .NET language with direct access to the whole .NET library. Being a .NET language also means it can smoothly interoperate with any other .NET language. F# supports both functional programming and procedural programming. It also fully supports object-oriented programming.

ML, Haskell, and F# are further discussed in Chapter 15.

2.5 The First Step Toward Sophistication: ALGOL 60

ALGOL 60 strongly influenced subsequent programming languages and is therefore of central importance in any historical study of languages.

2.5.1 Historical Background

ALGOL 60 was the result of efforts to design a universal programming language for scientific applications. By late 1954, the Laning and Zierler algebraic system had been in operation for over a year, and the first report on Fortran had been published. Fortran became a reality in 1957, and several other high-level languages were being developed. Most notable among them were IT, which was designed by Alan Perlis at Carnegie Tech, and two languages for the UNIVAC computers, MATH-MATIC and UNICODE. The proliferation of languages made program sharing among users difficult. Furthermore, the new languages were all growing up around single architectures, some for UNIVAC computers and some for IBM 700-series machines. In response to this blossoming of machine-dependent languages, several major computer user groups in the United States, including SHARE (the IBM scientific user group) and USE (UNIVAC Scientific Exchange, the large-scale UNIVAC scientific user group), submitted a petition to the Association for Computing Machinery (ACM) on May 10, 1957, to form a committee to study and recommend action to create a machine-independent scientific programming language. Although Fortran might have been a candidate, it could not become a universal language, because at the time it was solely owned by IBM.

Previously, in 1955, GAMM (a German acronym for Society for Applied Mathematics and Mechanics) had formed a committee to design one universal, machine-independent algorithmic language. The desire for this new language was in part due to the Europeans' fear of being dominated by IBM.

By late 1957, however, the appearance of several high-level languages in the United States convinced the GAMM subcommittee that their effort had to be widened to include the Americans, and a letter of invitation was sent to ACM. In April 1958, after Fritz Bauer of GAMM presented the formal proposal to ACM, the two groups officially agreed to a joint language design project.

2.5.2 Early Design Process

GAMM and ACM each sent four members to the first design meeting. The meeting, which was held in Zurich from May 27 to June 1, 1958, began with the following goals for the new language:

- The syntax of the language should be as close as possible to standard mathematical notation, and programs written in it should be readable with little further explanation.
- It should be possible to use the language for the description of algorithms in printed publications.
- Programs in the new language must be mechanically translatable into machine language.

The first goal indicated that the new language was to be used for scientific programming, which was the primary computer application area at that time. The second was something entirely new to the computing business. The last goal is an obvious necessity for any programming language.

The Zurich meeting succeeded in producing a language that met the stated goals, but the design process required innumerable compromises, both among individuals and between the two sides of the Atlantic. In some cases, the compromises were not so much over great issues as they were over spheres of influence. The question of whether to use a comma (the European method) or a period (the American method) for a decimal point is one example.

2.5.3 ALGOL 58 Overview

The language designed at the Zurich meeting was named the International Algorithmic Language (IAL). It was suggested during the design that the language be named ALGOL, for ALGOrithmic Language, but the name was rejected because it did not reflect the international scope of the committee. During the following year, however, the name was changed to ALGOL, and the language subsequently became known as ALGOL 58.

In many ways, ALGOL 58 was a descendant of Fortran, which is quite natural. It generalized many of Fortran's features and added several new constructs and concepts. Some of the generalizations had to do with the goal of not tying the language to any particular machine, and others were attempts to make the language more flexible and powerful. A rare combination of simplicity and elegance emerged from the effort.

ALGOL 58 formalized the concept of data type, although only variables that were not floating-point required explicit declaration. It added the idea of compound statements, which most subsequent languages incorporated. Some features of Fortran that were generalized were the following: Identifiers were allowed to have any length, as opposed to Fortran I's restriction to six or fewer characters; any number of array dimensions was allowed, unlike Fortran I's limitation to no more than three; the lower bound of arrays could be specified by the programmer, whereas in Fortran it was implicitly 1; nested selection statements were allowed, which was not the case in Fortran I.

ALGOL 58 acquired the assignment operator in a rather unusual way. Zuse used the form

- expression => variable

for the assignment statement in Plankalkül. Although Plankalkül had not yet been published, some of the European members of the ALGOL 58 committee were familiar with the language. The committee dabbled with the Plankalkül assignment form but, because of arguments about character set limitations,[4] the greater-than symbol was changed to a colon. Then, largely at the

insistence of the Americans, the whole statement was turned around to the Fortran form

4. The card punches of that time did not include the greater-than symbol.

- variable := expression

The Europeans preferred the opposite form, but that would be the reverse of Fortran.

2.5.4 Reception of the ALGOL 58 Report

In December 1958, publication of the ALGOL 58 report (Perlis and Samelson, 1958) was greeted with enthusiasm. In the United States, the new language was viewed more as a collection of ideas for programming language design than as a universal standard language. Actually, the ALGOL 58 report was not meant to be a finished product but rather a preliminary document for international discussion. Nevertheless, three major design and implementation efforts used the report as their basis. At the University of Michigan, the MAD language was born (Arden et al., 1961). The U.S. Naval Electronics Group produced the NELIAC language (Huskey et al., 1963). At System Development Corporation, JOVIAL was designed and implemented (Shaw, 1963). JOVIAL, an acronym for Jules' Own Version of the International Algebraic Language, represents the only language based on ALGOL 58 to achieve widespread use (Jules was Jules I. Schwartz, one of JOVIAL's designers). JOVIAL became widely used because it was the official scientific language for the U.S. Air Force for a quarter century.

The rest of the U.S. computing community was not so kind to the new language. At first, both IBM and its major scientific user group, SHARE, seemed to embrace ALGOL 58. IBM began an implementation shortly after the report was published, and SHARE formed a subcommittee, SHARE IAL, to study the language. The subcommittee subsequently recommended that ACM standardize ALGOL 58 and that IBM implement it for all of the 700-

series computers. The enthusiasm was short-lived, however. By the spring of 1959, both IBM and SHARE, through their Fortran experience, had had enough of the pain and expense of getting a new language started, both in terms of developing and using the first-generation compilers and in terms of training users in the new language and persuading them to use it. By the middle of 1959, both IBM and SHARE had developed such a vested interest in Fortran that they decided to retain it as *the* scientific language for the IBM 700-series machines, thereby abandoning ALGOL 58.

2.5.5 ALGOL 60 Design Process

During 1959, ALGOL 58 was furiously debated in both Europe and the United States. Large numbers of suggested modifications and additions were published in the European *ALGOL Bulletin* and in *Communications of the ACM*. One of the most important events of 1959 was the presentation of the work of the Zurich committee to the International Conference on Information Processing, for there Backus introduced his new notation for describing the syntax of programming languages, which later became known as BNF (Backus-Naur form). BNF is described in detail in Chapter 3.

In January 1960, the second ALGOL meeting was held, this time in Paris. The purpose of the meeting was to debate the 80 suggestions that had been formally submitted for consideration. Peter Naur of Denmark had become heavily involved in the development of ALGOL, even though he had not been a member of the Zurich group. It was Naur who created and published the *ALGOL Bulletin*. He spent a good deal of time studying Backus's paper that introduced BNF and decided that BNF should be used to describe formally the results of the 1960 meeting. After making a few relatively minor changes to BNF, he wrote a description of the new proposed language in BNF and handed it out to the members of the 1960 group at the beginning of the meeting.

2.5.6 ALGOL 60 Overview

Although the 1960 meeting lasted only six days, the modifications made to ALGOL 58 were dramatic. Among the most important new developments were the following:

- The concept of block structure was introduced. This allowed the programmer to localize parts of programs by introducing new data environments, or scopes.

- Two different means of passing parameters to subprograms were allowed: pass by value and pass by name.

- Procedures were allowed to be recursive. The ALGOL 58 description was unclear on this issue. Note that although recursion was new for the imperative languages, Lisp had already provided recursive functions in 1959.

- Stack-dynamic arrays were allowed. A stack-dynamic array is one for which the subscript range or ranges are specified by variables, so that the size of the array is set at the time storage is allocated to the array, which happens when the declaration is reached during execution. Stack-dynamic arrays are described in detail in Chapter 6.

Several features that might have had a dramatic impact on the success or failure of the language were proposed and rejected. Most important among these were input and output statements with formatting, which were omitted because they were thought to be machine-dependent.

The ALGOL 60 report was published in May 1960 (Naur, 1960). A number of ambiguities still remained in the language description, and a third meeting was scheduled for April 1962 in Rome to address the problems. At this meeting the group dealt only with problems; no additions to the language were allowed. The results of this meeting were published under the title "Revised Report on the Algorithmic Language ALGOL 60" (Backus et al., 1963).

2.5.7 Evaluation

In some ways, ALGOL 60 was a great success; in other ways, it was a dismal failure. It succeeded in becoming, almost immediately, the only acceptable formal means of communicating algorithms in computing literature, and it remained that for more than 20 years. Every imperative programming language designed since 1960 owes something to ALGOL 60. In fact, most are direct or indirect descendants; examples include PL/I, SIMULA 67, ALGOL 68, C, Pascal, Ada, C++, Java, and C#.

The ALGOL 58/ALGOL 60 design effort included a long list of firsts. It was the first time that an international group attempted to design a programming language. It was the first language that was designed to be machine independent. It was also the first language whose syntax was formally described. This successful use of the BNF formalism initiated several important fields of computer science: formal languages, parsing theory, and BNF-based compiler design. Finally, the structure of ALGOL 60 affected machine architecture. In the most striking example of this, an extension of the language was used as the systems language of a series of large-scale computers, the Burroughs B5000, B6000, and B7000 machines, which were designed with a hardware stack to implement efficiently the block structure and recursive subprograms of the language.

On the other side of the coin, ALGOL 60 never achieved widespread use in the United States. Even in Europe, where it was more popular than in the United States, it never became the dominant language. There are a number of reasons for its lack of acceptance. For one thing, some of the features of ALGOL 60 turned out to be too flexible; they made understanding difficult and implementation inefficient. The best example of this is the pass-by-name method of passing parameters to subprograms, which is explained in Chapter 9. The difficulties of implementing ALGOL 60 are evidenced by Rutishauser's statement in 1967 that few, if any, implementations included the full ALGOL 60 language (Rutishauser, 1967, p. 8).

The lack of input and output statements in the language was another major reason for its lack of acceptance. Implementation-dependent input/output made programs difficult to port to other computers.

Ironically, one of the most important contributions to computer science associated with ALGOL 60, BNF, was also a factor in its lack of acceptance.

Although BNF is now considered a simple and elegant means of syntax description, in 1960 it seemed strange and complicated.

Finally, although there were many other problems, the entrenchment of Fortran among users and the lack of support by IBM were probably the most important factors in ALGOL 60's failure to gain widespread use.

The ALGOL 60 effort was never really complete, in the sense that - ambiguities and obscurities were always a part of the language description (Knuth, 1967).

The following is an example of an ALGOL 60 program:

```
comment ALGOL 60 Example Program
 Input:  An integer, listlen, where listlen is less than
         100, followed by listlen-integer values
 Output: The number of input values that are greater than
         the average of all the input values ;
begin
  integer array intlist [1:99];
  integer listlen, counter, sum, average, result;
  sum := 0;
  result := 0;
  readint (listlen);
  if (listlen > 0) ^ (listlen < 100) then
    begin
comment Read input into an array and compute the average;
    for counter := 1 step 1 until listlen do
      begin
      readint (intlist[counter]);
      sum := sum + intlist[counter]
      end;
comment Compute the average;
    average := sum / listlen;
comment Count the input values that are > average;
    for counter := 1 step 1 until listlen do
      if intlist[counter] > average
        then result := result + 1;
comment Print result;
    printstring("The number of values > average is:");
    printint (result)
    end
  else
    printstring ("Error-input list length is not legal";
end
```

2.6 Computerizing Business Records: COBOL

The story of COBOL is, in a sense, the opposite of that of ALGOL 60. Although it has been used for nearly 60 years, COBOL has had little effect on the design of subsequent languages, except for PL/I. It may still be the most widely used language,5 although it is difficult to be sure one way or the other. Perhaps the most important reason why COBOL has had little influence is that few have attempted to design a new language for business applications since it appeared. That is due in part to how well COBOL's capabilities meet the needs of its application area. Another reason is that a great deal of growth in business computing over the past 30 years has occurred in small businesses. In these businesses, very little software development has taken place. Instead, most of the software used is purchased as off-the-shelf packages for various general business applications.

5. In the late 1990s, in a study associated with the Y2K problem, it was estimated that there were approximately 800 million lines of COBOL in regular use in the 22 square miles of Manhattan.

2.6.1 Historical Background

The beginning of COBOL is somewhat similar to that of ALGOL 60, in the sense that the language was designed by a committee of people meeting for relatively short periods of time. At the time, in 1959, the state of business computing was similar to the state of scientific computing several years earlier, when Fortran was being designed. One compiled language for business applications, FLOW-MATIC, had been implemented in 1957, but it belonged to one manufacturer, UNIVAC, and was designed for that company's computers. Another language, AIMACO, was being used by the U.S. Air Force, but it was only a minor variation of FLOW-MATIC. IBM had designed a programming language for business applications, COMTRAN

(COMmercial TRANslator), but it had not yet been implemented. Several other language design projects were being planned.

2.6.2 FLOW-MATIC

The origins of FLOW-MATIC are worth at least a brief discussion, because it was the primary progenitor of COBOL. In December 1953, Grace Hopper at Remington-Rand UNIVAC wrote a proposal that was indeed prophetic. It suggested that “mathematical programs should be written in mathematical notation, data processing programs should be written in English statements” (Wexelblat, 1981, p. 16). Unfortunately, in 1953, it was impossible to convince nonprogrammers that a computer could be made to understand English words. It was not until 1955 that a similar proposal had some hope of being funded by UNIVAC management, and even then it took a prototype system to do the final convincing. Part of this selling process involved compiling and running a small program, first using English keywords, then using French keywords, and then using German keywords. This demonstration was considered remarkable by UNIVAC management and was instrumental in their acceptance of Hopper’s proposal.

2.6.3 COBOL Design Process

The first formal meeting on the subject of a common language for business applications, which was sponsored by the Department of Defense, was held at the Pentagon on May 28 and 29, 1959 (exactly one year after the Zurich ALGOL meeting). The consensus of the group was that the language, then named CBL (Common Business Language), should have the following general characteristics: Most agreed that it should use English as much as possible, although a few argued for a more mathematical notation. The language must be easy to use, even at the expense of being less powerful, in order to broaden the base of those who could program computers. In addition to making the language easy to use, it was believed that the use of English would allow managers to read programs. Finally, the design should not be overly restricted by the problems of its implementation.

One of the overriding concerns at the meeting was that steps to create this universal language should be taken quickly, as a lot of work was already being done to create other business languages. In addition to the existing languages, RCA and Sylvania were working on their own business applications languages. It was clear that the longer it took to produce a universal language, the more difficult it would be for the language to become widely used. On this basis, it was decided that there should be a quick study of existing languages. For this task, the Short Range Committee was formed.

There were early decisions to separate the statements of the language into two categories—data description and executable operations—and to have statements in these two categories be in different parts of programs. One of the debates of the Short Range Committee was over the inclusion of subscripts. Many committee members argued that subscripts were too complex for the people in data processing, who were thought to be uncomfortable with mathematical notation. Similar arguments revolved around whether arithmetic expressions should be included. The final report of the Short Range Committee, which was completed in December 1959, described the language that was later named COBOL 60.

The language specification for COBOL 60, published by the Government Printing Office in April 1960 (Department of Defense, 1960), was described as “initial.” Revised versions were published in 1961 and 1962 (Department of Defense, 1961, 1962). The language was standardized by the American National Standards Institute (ANSI) group in 1968. The next three revisions were standardized by ANSI in 1974, 1985, and 2002. The language continues to evolve today.

2.6.4 Evaluation

The COBOL language originated a number of novel concepts, some of which eventually appeared in other languages. For example, the `DEFINE` verb of COBOL 60 was the first high-level language construct for macros. More important, hierarchical data structures (records), which first appeared in Plankalkül, were first implemented in COBOL. They have been included in most of the imperative languages designed since then. COBOL was also the

first language that allowed names to be truly connotative, because it allowed both long names (up to 30 characters) and word-connector characters (hyphens).

Overall, the data division is the strong part of COBOL's design, whereas the procedure division is relatively weak. Every variable is defined in detail in the data division, including the number of decimal digits and the location of the implied decimal point. File records are also described with this level of detail, as are lines to be output to a printer, which makes COBOL ideal for printing accounting reports. Perhaps the most important weakness of the original procedure division was in its lack of functions. Versions of COBOL prior to the 1974 standard also did not allow subprograms with parameters.

Our final comment on COBOL: It was the first programming language whose use was mandated by the Department of Defense (DoD). This mandate came after its initial development, because COBOL was not designed specifically for the DoD. In spite of its merits, COBOL probably would not have survived without that mandate. The poor performance of the early compilers simply made the language too expensive to use. Eventually, of course, compilers became more efficient and computers became much faster and cheaper and had much larger memories. Together, these factors allowed COBOL to succeed, inside and outside DoD. Its appearance led to the electronic mechanization of accounting, an important development by any measure.

The following is an example of a COBOL program. This program reads a file named `BAL-FWD-File` that contains inventory information about a certain collection of items. Among other things, each item record includes the number currently on hand (`BAL-ON-HAND`) and the item's reorder point (`BAL-REORDER-POINT`). The reorder point is the threshold number of items on hand at which more must be ordered. The program produces a list of items that must be reordered as a file named `REORDER-LISTING`.

2.7 The Beginnings of Timesharing: Basic

Basic (Mather and Waite, 1971) is another programming language that has enjoyed widespread use but has gotten little respect. Like COBOL, it has largely been ignored by computer scientists. Also, like COBOL, in its earliest versions it was inelegant and included only a meager set of control statements.

Basic was very popular on microcomputers in the late 1970s and early 1980s. This followed directly from two of the main characteristics of early versions of Basic. It was easy for beginners to learn, especially those who were not science oriented, and its smaller dialects could be implemented on computers with very small memories.6 When the capabilities of microcomputers grew and other languages were implemented, the use of Basic waned. A strong resurgence in the use of Basic began with the appearance of Visual Basic (Microsoft, 1991) in the early 1990s.

6. Some early microcomputers included Basic interpreters that resided in 4096 bytes of ROM.

2.7.1 Design Process

Basic (Beginner's All-purpose Symbolic Instruction Code) was originally designed at Dartmouth College (now Dartmouth University) in New Hampshire by two mathematicians, John Kemeny and Thomas Kurtz, who, in the early 1960s, developed compilers for a variety of dialects of Fortran and ALGOL 60. Their science students generally had little trouble learning or using those languages in their studies. However, Dartmouth was primarily a liberal arts institution, where science and engineering students made up only about 25 percent of the student body. It was decided in the spring of 1963 to design a new language especially for liberal arts students. This new language

would use terminals as the method of computer access. The goals of the system were as follows:

1. It must be easy for nonscience students to learn and use.
2. It must be “pleasant and friendly.”
3. It must provide fast turnaround for homework.
4. It must allow free and private access.
5. It must consider user time more important than computer time.

The last goal was indeed a revolutionary concept. It was based at least partly on the belief that computers would become significantly cheaper as time went on, which they certainly did.

The combination of the second, third, and fourth goals led to the time-shared aspect of Basic. Only with individual access through terminals by numerous simultaneous users could these goals be met in the early 1960s.

In the summer of 1963, Kemeny began work on the compiler for the first version of Basic, using remote access to a GE 225 computer. Design and coding of the operating system for Basic began in the fall of 1963. At 4:00 a.m. on May 1, 1964, the first program using the timeshared Basic was typed in and run. In June, the number of terminals on the system grew to 11, and by the fall it had ballooned to 20.

2.7.2 Language Overview

The original version of Basic was very small and, oddly, was not interactive: There was no way for an executing program to get input data from the user. Programs were typed in, compiled, and run, in a sort of batch-oriented way. The original Basic had only 14 different statement types and a single data type—floating-point. Because it was believed that few of the targeted users would appreciate the difference between integer and floating-point types, the type was referred to as “numbers.” Overall, it was a very limited language,

though quite easy to learn.

2.7.3 Evaluation

The most important aspect of the original Basic was that it was the first widely used language that was used through terminals connected to a remote computer.7 Terminals had just begun to be available at that time. Before then, most programs were entered into computers through either punched cards or paper tape.

7. Lisp initially was used through terminals, but it was not widely used in the early 1960s.

Much of the design of Basic came from Fortran, with some minor influence from the syntax of ALGOL 60. Later, it grew in a variety of ways, with little or no effort made to standardize it. The American National Standards Institute issued a Minimal Basic standard (ANSI, 1978b), but this represented only the bare minimum of language features. In fact, the original Basic was very similar to Minimal Basic.

Although it may seem surprising, Digital Equipment Corporation used a rather elaborate version of Basic named Basic-PLUS to write significant portions of their largest operating system for the PDP-11 minicomputers, RSTS, in the 1970s.

Basic has been criticized for the poor structure of programs written in it, among other things. By the evaluation criteria discussed in Chapter 1, specifically readability and reliability, the language does indeed fare very poorly. Clearly, the early versions of the language were not meant for and should not have been used for serious programs of any significant size. Later versions are much better suited to such tasks.

The resurgence of Basic in the 1990s was driven by the appearance of Visual Basic (VB). VB became widely used in large part because it provided a simple way of building graphical user interfaces (GUIs), hence the name Visual Basic. When .NET appeared, a new version of VB came with it,

VB.NET. Although it was a significant departure from earlier versions of VB, it quickly displaced the older language. Perhaps the most important difference between VB and the .NET version is that the later version fully supports object-oriented programming.

The following is an example of a Basic program:

```
REM  Basic Example Program
REM  Input:  An integer, listlen, where listlen is less
REM          than 100, followed by listlen-integer values
REM  Output: The number of input values that are greater
REM          than the average of all input values
  DIM intlist(99)
  result = 0
  sum = 0
  INPUT listlen
  IF listlen > 0 AND listlen < 100 THEN
REM  Read input into an array and compute the sum
   FOR counter = 1 TO listlen
     INPUT intlist(counter)
     sum = sum + intlist(counter)
   NEXT counter
REM  Compute the average
   average = sum / listlen
REM  Count the number of input values that are > average
   FOR counter = 1 TO listlen
     IF intlist(counter) > average
        THEN result = result + 1
   NEXT counter
REM  Print the result
    PRINT "The number of values that are > average is:";
          result
  ELSE
   PRINT "Error-input list length is not legal"
  END IF
END
```

interview

User Design and Language Design

ALAN COOPER

Best-selling author of About Face: The Essentials of User Interface Design, Alan Cooper also had a large hand in designing what can be touted as the language with the most concern for user interface design, Visual Basic. For him, it all comes down to a vision for humanizing technology.

SOME INFORMATION ON THE BASICS

How did you get started in all of this? I'm a high school dropout with an associate degree in programming from a California community college. My first job was as a programmer for American President Lines (one of the United States' oldest ocean transportation companies) in San Francisco. Except for a few months here and there, I've remained self-employed.

What is your current job? Founder and chairman of Cooper, the company that humanizes technology (www.cooper.com).

What is or was your favorite job? Interaction design consultant.

You are very well known in the fields of language design and user interface design. Any thoughts on designing languages versus designing software, versus designing anything else? It's pretty much the same in the world of software: Know your user.

ABOUT THAT EARLY WINDOWS RELEASE

In the 1980s, you started using Windows and have talked about being lured by its plusses: the graphical user interface support and the dynamically linked library that let you create tools that configured themselves. What about the parts of Windows that you eventually helped shape? I was very impressed by Microsoft's inclusion of support for practical multitasking in Windows. This included dynamic relocation and interprocess communications.

MSDOS.exe was the shell program for the first few releases of Windows. It was a terrible program, and I believed that it could be improved dramatically, and I was the guy to do it. In my spare time, I immediately began to write a better shell program than the one Windows came with. I called it Tripod. Microsoft's original shell, MSDOS.exe, was one of the main stumbling blocks to the initial success of Windows. Tripod attempted to solve the problem by being easier to use and to configure.

When was that "Aha!" moment? It wasn't until late in 1987, when I was interviewing a corporate client, that the key design strategy for Tripod popped into my head. As the IS manager explained to me his need to create and publish a wide range of shell solutions to his disparate user base, I realized the conundrum that there is no such thing as an ideal shell. Every user would need their own personal shell, configured to their own needs and skill levels. In an instant, I perceived the solution to the shell design problem: It would be a shell construction set; a tool where each user would be able to construct exactly the shell that he or she needed for a unique mix of applications and training.

What is so compelling about the idea of a shell that can be individualized? Instead of me telling the users what the ideal shell was, they could design their own, personalized ideal shell. With a customizable shell, a programmer would create a shell that was powerful and wide ranging but also somewhat dangerous, whereas an IT manager would create a shell that could be given to a desk clerk that exposed only those few application-specific tools that the clerk used.

> *"MSDOS.exe was the shell program for the first few releases of Windows. It was a terrible program, and I believed that it could be improved dramatically, and I was the guy to do it. In my spare time, I immediately began to write a better shell program than the one Windows came with."*

How did you get from writing a shell program to collaborating with Microsoft? Tripod and Ruby are the same thing. After I signed a deal with Bill Gates, I changed the name of the prototype from Tripod to Ruby. I then used the Ruby prototype as prototypes should be used: as a disposable model for constructing release-quality code. Which is what I did. MS took the release version of Ruby and added QuickBasic to it, creating VB. All of those original innovations were in Tripod/Ruby.

RUBY AS THE INCUBATOR FOR VISUAL BASIC

Let's revisit your interest in early Windows and that DLL feature. The DLL wasn't a thing, it was a facility in the OS. It allowed a programmer to build code objects that could be linked to at run time as opposed to only at compile time. This is what allowed me to invent the dynamically extensible parts of VB, where controls can be added by third-party vendors.

The Ruby product embodied many significant advances in software design, but two of them stand out as exceptionally successful. As I mentioned, the dynamic linking capability of Windows had always intrigued me, but having the tools and knowing what to do with them were two different things. With

Ruby, I finally found two practical uses for dynamic linking, and the original program contained both. First, the language was both installable and could be extended dynamically. Second, the palette of gizmos could be added to dynamically.

Was your language in Ruby the first to have a dynamic linked library and to be linked to a visual front end? As far as I know, yes.

Using a simple example, what would this enable a programmer to do with his or her program? Purchase a control, such as a grid control, from a third-party vendor, install it on his or her computer, and have the grid control appear as an integral part of the language, including the visual programming front end.

Why do they call you "the father of Visual Basic"? Ruby came with a small language, one suited only for executing the dozen or so simple commands that a shell program needs. However, this language was implemented as a chain of DLLs, any number of which could be installed at run time. The internal parser would identify a verb and then pass it along the chain of DLLs until one of them acknowledged that it knew how to process the verb. If all of the DLLs passed, there was a syntax error. From our earliest discussions, both Microsoft and I had entertained the idea of growing the language, possibly even replacing it altogether with a "real" language. C was the candidate most frequently mentioned, but eventually, Microsoft took advantage of this dynamic interface to unplug our little shell language and replace it entirely with Quick-Basic. This new marriage of language to visual front end was static and permanent, and although the original dynamic interface made the coupling possible, it was lost in the process.

SOME FINAL COMMENTS ON NEW IDEAS

In the world of programming and programming tools, including languages and environments, what projects most interest you? I'm interested in creating programming tools that are designed to help users

instead of programmers.

What's the most critical rule, famous quote, or design idea to keep in mind? Bridges are not built by engineers. They are built by ironworkers.

Similarly, software programs are not built by engineers. They are built by programmers.

2.8 Everything for Everybody: PL/I

PL/I represents the first large-scale attempt to design a language that could be used for a broad spectrum of application areas. All previous and most subsequent languages have focused on one particular application area, such as science, artificial intelligence, or business.

2.8.1 Historical Background

Like Fortran, PL/I was developed as an IBM product. By the early 1960s, the users of computers in industry had settled into two separate and quite different camps: scientific and business. From the IBM point of view, scientific programmers could use either the large-scale 7090 or the small-scale 1620 IBM computers. This group used floating-point data and arrays extensively. Fortran was the primary language, although some assembly language also was used. They had their own user group, SHARE, and had little contact with anyone who worked on business applications.

For business applications, people used the large 7080 or the small 1401 IBM computers. They needed the decimal and character string data types, as well as elaborate and efficient input and output facilities. They used COBOL, although in early 1963 when the PL/I story begins, the conversion from assembly language to COBOL was far from complete. This category of users also had its own user group, GUIDE, and seldom had contact with scientific users.

In early 1963, IBM planners perceived the beginnings of a change in this situation. The two widely separated computer user groups were moving toward each other in ways that were thought certain to create problems. Scientists began to gather large files of data to be processed. This data required more sophisticated and more efficient input and output facilities. Business applications people began to use regression analysis to build management information systems, which required floating-point data and

arrays. It began to appear that computing installations would soon require two separate computers and technical staffs, supporting two very different programming languages.8

8. At the time, large computer installations required both full-time hardware and full-time system software maintenance staff.

These perceptions naturally led to the concept of designing a single universal computer that would be capable of doing both floating-point and decimal arithmetic, and therefore both scientific and business applications. Thus was born the concept of the IBM System/360 line of computers. Along with this came the idea of a programming language that could be used for both business and scientific applications. For good measure, features to support systems programming and list processing were thrown in. Therefore, the new language was to replace Fortran, COBOL, Lisp, and the systems applications of assembly language.

2.8.2 Design Process

The design effort began when IBM and SHARE formed the Advanced Language Development Committee of the SHARE Fortran Project in October 1963. This new committee quickly met and formed a subcommittee called the 3 × 3 Committee, so named because it had three members from IBM and three from SHARE. The 3 × 3 Committee met for three or four days every other week to design the language.

As with the Short Range Committee for COBOL, the initial design was scheduled for completion in a remarkably short time. Apparently, regardless of the scope of a language design effort, in the early 1960s the prevailing belief was that it could be done in three months. The first version of PL/I, which was then named Fortran VI, was supposed to be completed by December, less than three months after the committee was formed. The committee pleaded successfully on two different occasions for extensions, moving the due date back to January and then to late February 1964.

The initial design concept was that the new language would be an extension

of Fortran IV, maintaining compatibility, but that goal was dropped quickly along with the name Fortran VI. Until 1965, the language was known as NPL (New Programming Language). The first published report on NPL was given at the SHARE meeting in March 1964. A more complete description followed in April, and the version that would actually be implemented was published in December 1964 (IBM, 1964) by the compiler group at the IBM Hursley Laboratory in England, which was chosen to do the implementation. In 1965, the name was changed to PL/I to avoid the confusion of the name NPL with the National Physical Laboratory in England. If the compiler had been developed outside the United Kingdom, the name might have remained NPL.

2.8.3 Language Overview

Perhaps the best single-sentence description of PL/I is that it included what were then considered the best parts of ALGOL 60 (recursion and block structure), Fortran IV (separate compilation with communication through global data), and COBOL 60 (data structures, input/output, and report-generating facilities), along with an extensive collection of new constructs, all somehow cobbled together. Because PL/I is no longer a popular language, we will not attempt, even briefly, to discuss all the features of the language, or even its most controversial constructs. Instead, we will mention some of the language's contributions to the pool of knowledge of programming languages.

PL/I was the first programming language to have the following facilities:

- Programs were allowed to create concurrently executing subprograms. Although this was a good idea, it was poorly developed in PL/I.
- It was possible to detect and handle 23 different types of exceptions, or run-time errors.
- Subprograms were allowed to be used recursively, but the capability could be disabled, allowing more efficient linkage for nonrecursive subprograms.

- Pointers were included as a data type.
- Cross-sections of arrays could be referenced. For example, the third row of a matrix could be referenced as if it were a single-dimensioned array.

2.8.4 Evaluation

Any evaluation of PL/I must begin by recognizing the ambitiousness of the design effort. In retrospect, it appears naive to think that so many constructs could have been combined successfully. However, that judgment must be tempered by acknowledging that there was little language design experience at the time. Overall, the design of PL/I was based on the premise that any construct that was useful and could be implemented should be included, with insufficient concern about how a programmer could understand and make effective use of such a collection of constructs and features. Edsger Dijkstra, in his Turing Award Lecture (Dijkstra, 1972), made one of the strongest criticisms of the complexity of PL/I: “I absolutely fail to see how we can keep our growing programs firmly within our intellectual grip when by its sheer baroqueness the programming language—our basic tool, mind you!—already escapes our intellectual control.”

In addition to the problem with the complexity due to its large size, PL/I suffered from a number of what are now considered to be poorly designed constructs. Among these were pointers, exception handling, and concurrency, although we must point out that in all cases, these constructs had not appeared in any previous language.

In terms of usage, PL/I must be considered at least a partial success. In the 1970s, it enjoyed significant use in both business and scientific applications. It was also widely used during that time as an instructional vehicle in colleges, primarily in several subset forms, such as PL/C (Cornell, 1977) and PL/CS (Conway and Constable, 1976).

The following is an example of a PL/I program:

```
/* PL/I PROGRAM EXAMPLE
 INPUT:   AN INTEGER, LISTLEN, WHERE LISTLEN IS LESS THAN
```

```
          100, FOLLOWED BY LISTLEN-INTEGER VALUES
 OUTPUT:  THE NUMBER OF INPUT VALUES THAT ARE GREATER THAN
          THE AVERAGE OF ALL INPUT VALUES */
PLIEX: PROCEDURE OPTIONS (MAIN);
  DECLARE INTLIST (1:99) FIXED.
  DECLARE (LISTLEN, COUNTER, SUM, AVERAGE, RESULT) FIXED;
  SUM = 0;
  RESULT = 0;
  GET LIST (LISTLEN);
  IF (LISTLEN > 0) & (LISTLEN < 100) THEN
    DO;
/* READ INPUT DATA INTO AN ARRAY AND COMPUTE THE SUM */
    DO COUNTER = 1 TO LISTLEN;
      GET LIST (INTLIST (COUNTER));
      SUM = SUM + INTLIST (COUNTER);
    END;
/* COMPUTE THE AVERAGE */
    AVERAGE = SUM / LISTLEN;
/* COUNT THE NUMBER OF VALUES THAT ARE > AVERAGE */
    DO COUNTER = 1 TO LISTLEN;
      IF INTLIST (COUNTER) > AVERAGE THEN
        RESULT = RESULT + 1;
    END;
/* PRINT RESULT */
    PUT SKIP LIST ('THE NUMBER OF VALUES > AVERAGE IS:');
    PUT LIST (RESULT);
    END;
ELSE
    PUT SKIP LIST ('ERROR-INPUT LIST LENGTH IS ILLEGAL');
END PLIEX;
```

2.9 Two Early Dynamic Languages: APL and SNOBOL

The structure of this section is different from that of the other sections because the languages discussed here are very different. Neither APL nor SNOBOL had much influence on later mainstream languages.9 Some of the interesting features of APL are discussed later in the book.

9. However, they have had some influence on some nonmainstream languages (J is based on APL, ICON is based on SNOBOL, and AWK is partially based on SNOBOL).

In appearance and in purpose, APL and SNOBOL are quite different. They share two fundamental characteristics, however: dynamic typing and dynamic storage allocation. Variables in both languages are essentially untyped. A variable acquires a type when it is assigned a value, at which time it assumes the type of the value assigned. Storage is allocated to a variable only when it is assigned a value, because before that there is no way to know the amount of storage that will be needed.

2.9.1 Origins and Characteristics of APL

APL (Brown et al., 1988) was designed around 1960 by Kenneth E. Iverson at IBM. It was not originally designed to be an implemented programming language but rather was intended to be a vehicle for describing computer architecture. APL was first described in the book from which it gets its name, *A Programming Language* (Iverson, 1962). In the mid-1960s, the first implementation of APL was developed at IBM.

APL has a large number of powerful operators that are specified with a large

number of symbols, which created a problem for implementors. Initially, APL was used through IBM printing terminals. These terminals had special optional print balls that provided the odd character set required by the -language. One reason APL has so many operators is that it provides a large number of unit operations on arrays. For example, the transpose of any matrix is done with a single operator. The large collection of operators provides very high expressivity but also makes APL programs difficult to read. Therefore, people think of APL as a language that is best used for "throw-away" programming. Although programs can be written quickly, they should be discarded after use because they are difficult to maintain.

APL has been around for over 55 years and is still used today, although not widely. Furthermore, it has not changed a great deal over its lifetime.

2.9.2 Origins and Characteristics of SNOBOL

SNOBOL (pronounced "snowball"; Griswold et al., 1971) was designed in the early 1960s by three people at Bell Laboratories: D. J. Farber, R. E. Griswold, and I. P. Polonsky (Farber et al., 1964). It was designed specifically for text processing. The heart of SNOBOL is a collection of powerful operations for string pattern matching. One of the early applications of SNOBOL was for writing text editors. Because the dynamic nature of SNOBOL makes it slower than alternative languages, it is no longer used for such programs. However, SNOBOL is still a live and supported language that is used for a variety of text-processing tasks in several different application areas.

2.10 The Beginnings of Data Abstraction: SIMULA 67

Although SIMULA 67 never achieved widespread use and had little impact on the programmers and computing of its time, some of the constructs it introduced make it historically important.

2.10.1 Design Process

Two Norwegians, Kristen Nygaard and Ole-Johan Dahl, developed the language SIMULA I between 1962 and 1964 at the Norwegian Computing Center (NCC) in Oslo. They were primarily interested in using computers for simulation but also worked in operations research. SIMULA I was designed exclusively for system simulation and was first implemented in late 1964 on a UNIVAC 1107 computer.

As soon as the SIMULA I implementation was completed, Nygaard and Dahl began efforts to extend the language by adding new features and modifying some existing constructs in order to make the language useful for general-purpose applications. The result of this work was SIMULA 67, whose design was first presented publicly in March 1967 (Dahl and Nygaard, 1967). We will discuss only SIMULA 67, although some of the features of interest in SIMULA 67 are also in SIMULA I.

2.10.2 Language Overview

SIMULA 67 is an extension of ALGOL 60, taking both block structure and the control statements from that language. The primary deficiency of ALGOL 60 (and other languages at that time) for simulation applications was the design of its subprograms. Simulation requires subprograms that are allowed to restart at the position where they previously stopped. Subprograms with

this kind of control are known as **coroutines** because the caller and called subprograms have a somewhat equal relationship with each other, rather than the rigid master/slave relationship they have in most imperative languages.

To provide support for coroutines in SIMULA 67, the class construct was developed. This was an important development because the concept of data abstraction began with it and data abstraction provides the foundation for object-oriented programming.

It is interesting to note that the important concept of data abstraction was not developed and attributed to the class construct until 1972, when Hoare (1972) recognized the connection.

2.11 Orthogonal Design: ALGOL 68

ALGOL 68 was the source of several new ideas in language design, some of which were subsequently adopted by other languages. We include it here for that reason, even though it never achieved widespread use in either Europe or the United States.

2.11.1 Design Process

The development of the ALGOL family did not end when the revised report on ALGOL 60 appeared in 1962, although it was six years until the next design iteration was published. The resulting language, ALGOL 68 (van Wijngaarden et al., 1969), was dramatically different from its predecessor.

One of the most interesting innovations of ALGOL 68 was one of its primary design criteria: orthogonality. Recall our discussion of orthogonality in Chapter 1. The use of orthogonality resulted in several innovative features of ALGOL 68, one of which is described in the following section.

2.11.2 Language Overview

One important result of orthogonality in ALGOL 68 was its inclusion of user-defined data types. Earlier languages, such as Fortran, included only a few basic data structures. PL/I included a larger number of data structures, which made it harder to learn and difficult to implement, but it still could not provide an appropriate data structure for every need.

The approach of ALGOL 68 to data structures was to provide a few primitive types and structures and allow the user to combine those primitives to define a large number of different structures. This provision for user-defined data types was carried over to some extent into all of the major imperative languages designed since then. User-defined data types are valuable because

they allow the user to design data abstractions that fit particular problems very closely. All aspects of data types are discussed in Chapter 6.

As another first in the area of data types, ALGOL 68 introduced the kind of dynamic arrays that will be termed *implicit heap-dynamic* in Chapter 5. A dynamic array is one in which the declaration does not specify subscript bounds. Assignments to a dynamic array cause allocation of required storage. In ALGOL 68, dynamic arrays are called **`flex`** arrays.

2.11.3 Evaluation

ALGOL 68 includes a significant number of features that had not been previously used. Its use of orthogonality, which some may argue was overdone, was nevertheless revolutionary.

ALGOL 68 repeated one of the sins of ALGOL 60, however, and it was an important factor in its limited popularity. The language was described using an elegant and concise but also unknown metalanguage. Before one could read the language-describing document (van Wijngaarden et al., 1969), he or she had to learn the new metalanguage, called van Wijngaarden grammars, which were far more complex than BNF. To make matters worse, the designers invented a collection of words to explain the grammar and the language. For example, keywords were called *indicants*, substring extraction was called *trimming*, and the process of a subprogram execution was called a *coercion of deproceduring*, which might be *meek*, *firm*, or something else.

It is natural to contrast the design of PL/I with that of ALGOL 68, because they appeared only a few years apart. ALGOL 68 achieved writability by the principle of orthogonality: a few primitive concepts and the unrestricted use of a few combining mechanisms. PL/I achieved writability by including a large number of fixed constructs. ALGOL 68 extended the elegant simplicity of ALGOL 60, whereas PL/I simply threw together the features of several languages to attain its goals. Of course, it must be remembered that the goal of PL/I was to provide a unified tool for a broad class of problems, whereas ALGOL 68 was targeted to a single class: scientific applications.

PL/I achieved far greater acceptance than ALGOL 68, due largely to IBM's promotional efforts and the problems of understanding and implementing ALGOL 68. Implementation was a difficult problem for both, but PL/I had the resources of IBM to apply to building a compiler. ALGOL 68 enjoyed no such benefactor.

2.12 Some Early Descendants of the ALGOLs

All imperative languages owe some of their design to ALGOL 60 and/or ALGOL 68. This section discusses some of the early descendants of these languages.

2.12.1 Simplicity by Design: Pascal

2.12.1.1 Historical Background

Niklaus Wirth (Wirth is pronounced “Virt”) was a member of the International Federation of Information Processing (IFIP) Working Group 2.1, which was created to continue the development of ALGOL in the mid-1960s. In August 1965, Wirth and C. A. R. (“Tony”) Hoare contributed to that effort by presenting to the group a somewhat modest proposal for additions and modifications to ALGOL 60 (Wirth and Hoare, 1966). The majority of the group rejected the proposal as being too small an improvement over ALGOL 60. Instead, a much more complex revision was developed, which eventually became ALGOL 68. Wirth, along with a few other group members, did not believe that the ALGOL 68 report should have been released, based on the complexity of both the language and the metalanguage used to describe it. This position later proved to have some validity because the ALGOL 68 documents, and therefore the language, were indeed found to be challenging by the computing community.

The Wirth and Hoare version of ALGOL 60 was named ALGOL-W. It was implemented at Stanford University and was used primarily as an instructional vehicle, but only at a few universities. The primary contributions of ALGOL-W were the value-result method of passing parameters and the **`case`** statement for multiple selection. The value-result

method is an alternative to ALGOL 60's pass-by-name method. Both are discussed in Chapter 9. The **case** statement is discussed in Chapter 8.

Wirth's next major design effort, again based on ALGOL 60, was his most successful: Pascal.10 The original published definition of Pascal appeared in 1971 (Wirth, 1971). This version was modified somewhat in the implementation process and is described in Wirth (1973). The features that are often ascribed to Pascal in fact came from earlier languages. For example, user-defined data types were introduced in ALGOL 68, the **case** statement in ALGOL-W, and Pascal's records are similar to those of COBOL and PL/I.

10. Pascal is named after Blaise Pascal, a seventeenth-century French philosopher and mathematician who invented the first mechanical adding machine in 1642 (among other things).

2.12.1.2 Evaluation

The largest impact of Pascal was on the teaching of programming. In 1970, most students of computer science, engineering, and science were introduced to programming with Fortran, although some universities used PL/I, languages based on PL/I, and ALGOL-W. By the mid-1970s, Pascal had become the most widely used language for this purpose. This was quite natural, because Pascal was designed specifically for teaching programming. It was not until the late 1990s that Pascal was no longer the most commonly used language for teaching programming in colleges and universities.

Because Pascal was designed as a teaching language, it lacks several features that are essential for many kinds of applications. The best example of this is the impossibility of writing a subprogram that takes as a parameter an array of variable length. Another example is the lack of any separate compilation capability. These deficiencies naturally led to many nonstandard dialects, such as Turbo Pascal.

Pascal's popularity, for both teaching programming and other applications, was based primarily on its remarkable combination of simplicity and expressivity. Although there are some insecurities in Pascal, it is still a

relatively safe language, particularly when compared with Fortran or C. By the mid-1990s, the popularity of Pascal was on the decline, both in industry and in universities, primarily due to the rise of Modula-2, Ada, and C++, all of which included features not available in Pascal.

The following is an example of a Pascal program:

```
{Pascal Example Program
 Input:   An integer, listlen, where listlen is less than
          100, followed by listlen-integer values
 Output:  The number of input values that are greater than
          the average of all input values }
program pasex (input, output);
  type intlisttype = array [1..99] of integer;
  var
    intlist : intlisttype;
    listlen, counter, sum, average, result : integer;
  begin
  result := 0;
  sum := 0;
  readln (listlen);
  if ((listlen > 0) and (listlen < 100)) then
    begin
{ Read input into an array and compute the sum }
  for counter := 1 to listlen do
    begin
    readln (intlist[counter]);
    sum := sum + intlist[counter]
    end;
{ Compute the average }
    average := sum / listlen;
{ Count the number of input values that are > average }
      for counter := 1 to listlen do
        if (intlist[counter] > average) then
          result := result + 1;
{ Print the result }
    writeln ('The number of values > average is:',
              result)
    end  { of the then clause of if (( listlen > 0 ... }
  else
    writeln ('Error-input list length is not legal')
end.
```

2.12.2 A Portable Systems

Language: C

Like Pascal, C contributed little to the previously known collection of language features, but it has been widely used over a long period of time. Although originally designed for systems programming, C is well suited for a wide variety of applications.

2.12.2.1 Historical Background

C's ancestors include CPL, BCPL, B, and ALGOL 68. CPL was developed at Cambridge University in the early 1960s. BCPL is a simple systems language, also developed at Cambridge, this time by Martin Richards in 1967 (Richards, 1969).

The first work on the UNIX operating system was done in the late 1960s by Ken Thompson at Bell Laboratories. The first version was written in assembly language. The first high-level language implemented under UNIX was B, which was based on BCPL. B was designed and implemented by Thompson in 1970.

Neither BCPL nor B is a typed language, which is an oddity among high-level languages, although both are much lower-level than a language such as Java. Being untyped means that all data are considered machine words, which, although simple, leads to many complications and insecurities. For example, there is the problem of specifying floating-point rather than integer arithmetic in an expression. In one implementation of BCPL, the variable operands of a floating-point operation were preceded by periods. Variable operands not preceded by periods were considered to be integers. An alternative to this would have been to use different symbols for the floating-point operators.

This problem, along with several others, led to the development of a new typed language based on B. Originally called NB but later named C, it was designed and implemented by Dennis Ritchie at Bell Laboratories in 1972 (Kernighan and Ritchie, 1978). In some cases through BCPL, and in other

cases directly, C was influenced by ALGOL 68. This is seen in its **`for`** and **`switch`** statements, in its assigning operators, and in its treatment of pointers.

The only “standard” for C in its first decade and a half was the book by Kernighan and Ritchie (1978).11 Over that time span, the language slowly evolved, with different implementors adding different features. In 1989, ANSI produced an official description of C (ANSI, 1989), which included many of the features that implementors had already incorporated into the language. This standard was updated in 1999 (ISO, 1999). This later version includes a few significant changes to the language. Among these are a complex data type, a Boolean data type, and C++-style comments (`//`). We will refer to the 1989 version, which has long been called ANSI C, as C89; we will refer to the 1999 version as C99.

11. This language is often referred to as “K & R C.”

2.12.2.2 Evaluation

C has adequate control statements and data-structuring facilities to allow its use in many application areas. It also has a rich set of operators that provide a high degree of expressiveness.

One of the most important reasons why C is both liked and disliked is its lack of complete type checking. For example, in versions before C99, functions could be written for which parameters were not type checked. Those who like C appreciate the flexibility; those who do not like it find it too insecure. A major reason for its great increase in popularity in the 1980s was that a compiler for it was part of the widely used UNIX operating system. This inclusion in UNIX provided an essentially free and quite good compiler that was available to programmers on many different kinds of computers.

The following is an example of a C program:

```
/* C Example Program
 Input:  An integer, listlen, where listlen is less than
         100, followed by listlen-integer values
 Output: The number of input values that are greater than
```

```
         the average of all input values */
int main (){
  int intlist[99], listlen, counter, sum, average, result;
  sum = 0;
  result = 0;
  scanf("%d", &listlen);
  if ((listlen > 0) && (listlen < 100)) {
/* Read input into an array and compute the sum */
    for (counter = 0; counter < listlen; counter++) {
     scanf("%d", &intlist[counter]);
     sum += intlist[counter];
    }
/* Compute the average */
    average = sum / listlen;
/* Count the input values that are > average */
     for  (counter = 0; counter < listlen; counter++)
       if  (intlist[counter] > average) result++;
/* Print result */
    printf("Number of values > average is:%d\n", result);
  }
  else
    printf("Error-input list length is not legal\n");
}
```

2.13 Programming Based on Logic: Prolog

Simply put, logic programming is the use of a formal logic notation to communicate computational processes to a computer. Predicate calculus is the notation used in current logic programming languages.

Programming in logic programming languages is nonprocedural. Programs in such languages do not state exactly *how* a result is to be computed but rather describe the necessary form and/or characteristics of the result. What is needed to provide this capability in logic programming languages is a concise means of supplying the computer with both the relevant information and an inferencing process for computing desired results. Predicate calculus supplies the basic form of communication to the computer, and the proof method, named **resolution**, developed first by Robinson (1965), supplies the inferencing technique.

2.13.1 Design Process

During the early 1970s, Alain Colmerauer and Phillippe Roussel in the - Artificial Intelligence Group at the University of Aix-Marseille, together with Robert Kowalski of the Department of Artificial Intelligence at the University of Edinburgh, developed the fundamental design of Prolog. The primary components of Prolog are a method for specifying predicate calculus propositions and an implementation of a restricted form of resolution. Both predicate calculus and resolution are described in Chapter 16. The first Prolog interpreter was developed at Marseille in 1972. The version of the language that was implemented is described in Roussel (1975). The name Prolog is from *pro*gramming *log*ic.

2.13.2 Language Overview

Prolog programs consist of collections of statements. Prolog has only a few kinds of statements, but they can be complex.

One common use of Prolog is as a kind of intelligent database. This application provides a simple framework for discussing the Prolog language.

The database of a Prolog program consists of two kinds of statements: facts and rules. The following are examples of fact statements:

```
mother(joanne, jake).
father(vern, joanne).
```

These state that `joanne` is the `mother` of `jake`, and `vern` is the `father` of `joanne`.

An example of a rule statement is

```
grandparent(X, Z) :- parent(X, Y), parent(Y, Z).
```

This states that it can be deduced that `X` is the `grandparent` of `Z` if it is true that `X` is the `parent` of `Y` and `Y` is the parent of `Z`, for some specific values for the variables `X`, `Y`, and `Z`.

The Prolog database can be interactively queried with goal statements, an example of which is

```
father(bob, darcie).
```

This asks if `bob` is the `father` of `darcie`. When such a query, or goal, is presented to the Prolog system, it uses its resolution process to attempt to determine the truth of the statement. If it can conclude that the goal is true, it displays “true.” If it cannot prove it, it displays “false.”

2.13.3 Evaluation

In the 1980s, there was a relatively small group of computer scientists who believed that logic programming provided the best hope for escaping from the complexity of imperative languages, and also from the enormous problem

of producing the large amount of reliable software that was needed. So far, however, there are two major reasons why logic programming has not become more widely used. First, as with some other nonimperative approaches, programs written in logic languages thus far have proven to be highly inefficient relative to equivalent imperative programs. Second, it has been determined that it is an effective approach for only a few relatively small areas of application: certain kinds of database management systems and some areas of AI.

There is a dialect of Prolog that supports object-oriented programming: Prolog++ (Moss, 1994). Logic programming and Prolog are described in greater detail in Chapter 16.

2.14 History's Largest Design Effort: Ada

The Ada language is the result of the most extensive and expensive language design effort ever undertaken. The following paragraphs briefly describe the evolution of Ada.

2.14.1 Historical Background

The Ada language was developed for the Department of Defense (DoD), so the state of their computing environment was instrumental in determining its form. By 1974, over half of the applications of computers in DoD were embedded systems. An embedded system is one in which the computer hardware is embedded in the device it controls or for which it provides services. Software costs were rising rapidly, primarily because of the increasing complexity of systems. More than 450 different programming languages were in use for DoD projects, and none of them was standardized by DoD. Every defense contractor could define a new and different language for every contract.12 Because of this language proliferation, application software was rarely reused. Furthermore, no software development tools were created (because they are usually language dependent). A great many languages were in use, but none was actually suitable for embedded systems applications. For these reasons, in 1974, the Army, Navy, and Air Force each independently proposed the development of a single high-level language for embedded systems.

12. This result was largely due to the widespread use of assembly language for embedded systems, along with the fact that most embedded systems used specialized processors.

2.14.2 Design Process

Noting this widespread interest, in January 1975, Malcolm Currie, director of Defense Research and Engineering, formed the High-Order Language Working Group (HOLWG), initially headed by Lt. Col. William Whitaker of the Air Force. The HOLWG had representatives from all of the military services and liaisons with Great Britain, France, and what was then West Germany. Its initial charter was to do the following:

- Identify the requirements for a new DoD high-level language.
- Evaluate existing languages to determine whether there was a viable candidate.
- Recommend adoption or implementation of a minimal set of programming languages.

In April 1975, the HOLWG produced the Strawman requirements document for the new language (Department of Defense, 1975a). This was distributed to military branches, federal agencies, selected industrial and university representatives, and interested parties in Europe.

The Strawman document was followed by Woodenman (Department of Defense, 1975b) in August 1975, Tinman (Department of Defense, 1976) in January 1976, Ironman (Department of Defense, 1977) in January 1977, and finally Steelman (Department of Defense, 1978) in June 1978.

After a tedious process, the many submitted proposals for the language were narrowed down to four finalists, all of which were based on Pascal. In May 1979, the Cii Honeywell/Bull language design proposal was chosen from the four finalists as the design that would be used. The Cii Honeywell/Bull design team in France, the only foreign competitor among the final four, was led by Jean Ichbiah.

In the spring of 1979, Jack Cooper of the Navy Materiel Command recommended the name for the new language, Ada, which was then adopted. The name commemorates Augusta Ada Byron (1815–1851), countess of Lovelace, mathematician, and daughter of poet Lord Byron. She is generally recognized as being the world's first programmer. She worked with Charles Babbage on his mechanical computers, the Difference and Analytical

Engines, writing programs for several numerical processes.

The design and the rationale for Ada were published by ACM in its *SIGPLAN Notices* (ACM, 1979) and distributed to a readership of more than 10,000 people. A public test and evaluation conference was held in October 1979 in Boston, with representatives from over 100 organizations from the United States and Europe. By November, more than 500 language reports had been received from 15 different countries. Most of the reports suggested small modifications rather than drastic changes and outright rejections. Based on the language reports, the next version of the requirements specification, the Stoneman document (Department of Defense, 1980), was released in February 1980.

A revised version of the language design was completed in July 1980 and was accepted as MIL-STD 1815, the standard *Ada Language Reference Manual*. The number 1815 was chosen because it was the year of the birth of Augusta Ada Byron. Another revised version of the *Ada Language Reference Manual* was released in July 1982. In 1983, the American National Standards Institute standardized Ada. This “final” official version is described in Goos and Hartmanis (1983). The Ada language design was then frozen for a minimum of five years.

2.14.3 Language Overview

This subsection briefly describes four of the major contributions of the Ada language.

Packages in the Ada language provide the means for encapsulating data objects, specifications for data types, and procedures. This, in turn, provides the support for the use of data abstraction in program design.

The Ada language includes extensive facilities for exception handling, which allow the programmer to gain control after any one of a wide variety of exceptions, or run-time errors, has been detected.

Program units can be generic in Ada. For example, it is possible to write a

sort procedure that uses an unspecified type for the data to be sorted. Such a generic procedure must be instantiated for a specified type before it can be used, which is done with a statement that causes the compiler to generate a version of the procedure with the given type. The availability of such generic units increases the range of program units that might be reused, rather than duplicated, by programmers.

The Ada language also provides for concurrent execution of special program units, named tasks, using the rendezvous mechanism. Rendezvous is the name of a method of intertask communication and synchronization.

2.14.4 Evaluation

Perhaps the most important aspects of the design of the Ada language to consider are the following:

- Because the design was competitive, there were no limits on participation.
- The Ada language embodies most of the concepts of software engineering and language design of the late 1970s. Although one can question the actual approaches used to incorporate these features, as well as the wisdom of including such a large number of features in a language, most agree that the features are valuable.
- Although most people did not anticipate it, the development of a compiler for the Ada language was a difficult task. Only in 1985, almost four years after the language design was completed, did truly usable Ada compilers begin to appear.

The most serious criticism of Ada in its first few years was that it was too large and too complex. In particular, Hoare (1981) stated that it should not be used for any application where reliability is critical, which is precisely the type of application for which it was designed. On the other hand, others have praised it as the epitome of language design for its time. In fact, even Hoare eventually softened his view of the language.

The following is an example of an Ada program:

```
-- Ada Example Program
-- Input:   An integer, List_Len, where List_Len is less
--          than 100, followed by List_Len-integer values
-- Output:  The number of input values that are greater
--          than the average of all input values
with Ada.Text_IO, Ada.Integer.Text_IO;
use Ada.Text_IO, Ada.Integer.Text_IO;
procedure Ada_Ex is
  type Int_List_Type is array (1..99) of Integer;
  Int_List : Int_List_Type;
  List_Len, Sum, Average, Result : Integer;
begin
  Result:= 0;
  Sum := 0;
  Get (List_Len);
  if (List_Len > 0) and (List_Len < 100) then
-- Read input data into an array and compute the sum
    for Counter := 1 .. List_Len loop
      Get (Int_List(Counter));
      Sum := Sum + Int_List(Counter);
    end loop;
-- Compute the average
    Average := Sum / List_Len;
-- Count the number of values that are > average
    for Counter := 1 .. List_Len loop
      if Int_List(Counter) > Average then
        Result:= Result+ 1;
      end if;
    end loop;
-- Print result
    Put ("The number of values > average is:");
    Put (Result);
    New_Line;
  else
    Put_Line ("Error-input list length is not legal");
  end if;
end Ada_Ex;
```

2.14.5 Ada 95 and Ada 2005

Two of the most important new features of Ada 95 are described briefly in the following paragraphs. In the remainder of the book, we will use the name

Ada 83 for the original version and Ada 95 (its actual name) for the later version when it is important to distinguish between the two versions. In discussions of language features common to both versions, we will use the name Ada. The Ada 95 standard language is defined in ARM (1995).

The type derivation mechanism of Ada 83 is extended in Ada 95 to allow adding new components to those inherited from a base class. This provides for inheritance, a key ingredient in object-oriented programming languages. Dynamic binding of subprogram calls to subprogram definitions is accomplished through subprogram dispatching, which is based on the tag value of derived types through classwide types. This feature provides for polymorphism, another principal feature of object-oriented programming.

The rendezvous mechanism of Ada 83 provided only a cumbersome and inefficient means of sharing data among concurrent processes. It was necessary to introduce a new task to control access to the shared data. The protected objects of Ada 95 offer an attractive alternative to this. The shared data is encapsulated in a syntactic structure that controls all access to the data, either by rendezvous or by subprogram call.

It is widely believed that the popularity of Ada 95 suffered because the Department of Defense stopped requiring its use in military software systems. There were, of course, other factors that hindered its growth in popularity. Most important among these was the widespread acceptance of C++ for object-oriented programming, which occurred before Ada 95 was released.

There were several additions to Ada 95 to get Ada 2005. Among these were interfaces, similar to those of Java, more control of scheduling algorithms, and synchronized interfaces.

Ada is widely used in both commercial and defense avionics, air traffic control, and rail transportation, as well as in other areas.

2.15 Object-Oriented Programming: Smalltalk

Smalltalk was the first programming language that fully supported object--oriented programming. It is therefore an important part of any discussion of the evolution of programming languages.

2.15.1 Design Process

The concepts that led to the development of Smalltalk originated in the Ph.D. dissertation work of Alan Kay in the late 1960s at the University of Utah (Kay, 1969). Kay had the remarkable foresight to predict the future availability of powerful desktop computers. Recall that the first microcomputer systems were not marketed until the mid-1970s, and they were only remotely related to the machines envisioned by Kay, which were seen to execute a million or more instructions per second and contain several megabytes of memory. Such machines, in the form of workstations, became widely available only in the early 1980s.

Kay believed that desktop computers would be used by nonprogrammers and thus would need very powerful human-interfacing capabilities. The computers of the late 1960s were largely batch oriented and were used exclusively by professional programmers and scientists. For use by nonprogrammers, Kay determined, a computer would have to be highly interactive and use sophisticated graphics in its user interface. Some of the graphics concepts came from the LOGO experience of Seymour Papert, in which graphics were used to aid children in the use of computers (Papert, 1980).

Kay originally envisioned a system he called Dynabook, which was meant to be a general information processor. It was based in part on the Flex language, which he had helped design. Flex was based primarily on SIMULA 67.

Dynabook used the paradigm of the typical desk, on which there are a number of papers, some partially covered. The top sheet is often the focus of attention, with the others temporarily out of focus. The display of Dynabook would model this scene, using screen windows to represent various sheets of paper on the desktop. The user would interact with such a display both through keystrokes and by touching the screen with his or her fingers. After the preliminary design of Dynabook earned him a Ph.D., Kay's goal became to see such a machine constructed.

Kay found his way to the Xerox Palo Alto Research Center (Xerox PARC) and presented his ideas on Dynabook. This led to his employment there and the subsequent birth of the Learning Research Group at Xerox. The first charge of the group was to design a language to support Kay's programming paradigm and implement it on the best personal computer then available. These efforts resulted in an "Interim" Dynabook, consisting of a Xerox Alto workstation and Smalltalk-72 software. Together, they formed a research tool for further development. A number of research projects were conducted with this system, including several experiments to teach programming to children. Along with the experiments came further developments, leading to a sequence of languages that ended with Smalltalk-80. As the language grew, so did the power of the hardware on which it resided. By 1980, both the language and the Xerox hardware nearly matched the early vision of Alan Kay.

2.15.2 Language Overview

The Smalltalk world is populated by nothing but objects, from integer constants to large complex software systems. All computing in Smalltalk is done by the same uniform technique: sending a message to an object to invoke one of its methods. A reply to a message is an object, which either returns the requested information or simply notifies the sender that the requested processing has been completed. The fundamental difference between a message and a subprogram call is this: A message is sent to a data object, specifically to one of the methods defined for the object. The called method is then executed, often modifying the data of the object to which the message was sent; a subprogram call is a message to the code of a

subprogram. Usually the data to be processed by the subprogram is sent to it as a parameter.[13]

13. Of course, a method call can also pass data to be processed by the called method.

In Smalltalk, object abstractions are classes, which are very similar to the classes of SIMULA 67. Instances of the class can be created and are then the objects of the program.

The syntax of Smalltalk is unlike that of most other programming language, in large part because of the use of messages, rather than arithmetic and logic expressions and conventional control statements. One of the Smalltalk control constructs is illustrated in the example in the next subsection.

2.15.3 Evaluation

Smalltalk has done a great deal to promote two separate aspects of computing: graphical user interfaces and object-oriented programming. The windowing systems that are now the dominant method of user interfaces to software systems grew out of Smalltalk. Today, the most significant software design methodologies and programming languages are object oriented. Although the origin of some of the ideas of object-oriented languages came from SIMULA 67, they reached maturation in Smalltalk. It is clear that Smalltalk's impact on the computing world is extensive and will be long-lived.

The following is an example of a Smalltalk class definition:

```
"Smalltalk Example Program"
"The following is a class definition, instantiations of which can
class name                    Polygon
superclass                    Object
instance variable names       ourPen
numSides
sideLength
"Class methods"
  "Create an instance"
```

```
new
   ^ super new getPen
"Get a pen for drawing polygons"
getPen
   ourPen <- Pen new defaultNib: 2
"Instance methods"
"Draw a polygon"
draw
   numSides timesRepeat: [ourPen go: sideLength;
                            turn: 360 // numSides]
"Set length of sides"
length: len
sideLength <- len
"Set number of sides"
sides: num
   numSides <- num
```

2.16 Combining Imperative and Object-Oriented Features: C++

The origins of C were discussed in Section 2.12; the origins of Simula 67 were discussed in Section 2.10; the origins of Smalltalk were discussed in Section 2.15. C++ builds language facilities, borrowed from Simula 67, on top of C to support much of what Smalltalk pioneered. C++ has evolved from C through a sequence of modifications to improve its imperative features and to add constructs to support object-oriented programming.

2.16.1 Design Process

The first step from C toward C++ was made by Bjarne Stroustrup at Bell Laboratories in 1980. The initial modifications to C included the addition of function parameter type checking and conversion and, more significantly, classes, which are related to those of SIMULA 67 and Smalltalk. Also included were derived classes, public/private access control of inherited components, constructor and destructor methods, and friend classes. During 1981, inline functions, default parameters, and overloading of the assignment operator were added. The resulting language was called C with Classes and is described in Stroustrup (1983).

It is useful to consider some goals of C with Classes. The primary goal was to provide a language in which programs could be organized as they could be organized in SIMULA 67—that is, with classes and inheritance. A second important goal was that there should be little or no performance penalty relative to C. For example, array index range checking was not even considered because a significant performance disadvantage, relative to C, would result. A third goal of C with Classes was that it could be used for every application for which C could be used, so virtually none of the features of C would be removed, not even those considered to be unsafe.

By 1984, this language was extended by the inclusion of virtual methods, which provide dynamic binding of method calls to specific method definitions, method name and operator overloading, and reference types. This version of the language was called C++. It is described in Stroustrup (1984).

In 1985, the first available implementation appeared: a system named Cfront, which translated C++ programs into C programs. This version of Cfront and the version of C++ it implemented were named Release 1.0. It is described in Stroustrup (1986).

Between 1985 and 1989, C++ continued to evolve, based largely on user reactions to the first distributed implementation. This next version was named Release 2.0. Its Cfront implementation was released in June 1989. The most important features added to C++ Release 2.0 were support for multiple inheritance (classes with more than one parent class) and abstract classes, along with some other enhancements. Abstract classes are described in Chapter 12.

Release 3.0 of C++ evolved between 1989 and 1990. It added templates, which provide parameterized types, and exception handling. The current version of C++, which was standardized in 1998, is described in ISO (1998).

In 2002, Microsoft released its .NET computing platform, which included a new version of C++, named Managed C++, or MC++. MC++ extends C++ to provide access to the functionality of the .NET Framework. The additions include properties, delegates, interfaces, and a reference type for garbage--collected objects. Properties are discussed in Chapter 11. Delegates are briefly discussed in the introduction to C# in Section 2.19. Because .NET does not support multiple inheritance, neither does MC++.

2.16.2 Language Overview

Because C++ has both functions and methods, it supports both procedural and object-oriented programming.

Operators in C++ can be overloaded, meaning the user can create operators

for existing operators on user-defined types. C++ methods can also be overloaded, meaning the user can define more than one method with the same name, provided either the numbers or types of their parameters are different.

Dynamic binding in C++ is provided by virtual methods. These methods define type-dependent operations, using overloaded methods, within a collection of classes that are related through inheritance. A pointer to an object of class A can also point to objects of classes that have class A as an ancestor. When this pointer points to an overloaded virtual method, the method of the current type is chosen dynamically.

Both methods and classes can be templated, which means that they can be parameterized. For example, a method can be written as a templated method to allow it to have versions for a variety of parameter types. Classes enjoy the same flexibility.

C++ supports multiple inheritance. The exception-handling constructs of C++ are discussed in Chapter 14.

2.16.3 Evaluation

C++ rapidly became and remains a widely used language. One factor in its popularity is the availability of good and inexpensive compilers. Another factor is that it is almost completely backward compatible with C (meaning that C programs, with few changes, can be compiled as C++ programs), and in most implementations it is possible to link C++ code with C code—and thus relatively easy for the many C programmers to learn C++. Finally, at the time C++ first appeared, when object-oriented programming began to receive widespread interest, C++ was the only available language that was suitable for large commercial software projects.

On the negative side, because C++ is a very large and complex language, it clearly suffers drawbacks similar to those of PL/I. It inherited most of the insecurities of C, which make it less safe than languages such as Ada and Java.

2.16.4 A Replacement for Objective-C, Swift

Beginning with MAC OS X in 2002, Apple systems software was written in Objective-C. Swift was developed by Apple as an improved replacement for Objective-C. Work on Swift began in 2010 by Chris Lattner. The language was introduced in 2014, with version 2 being introduced in 2015. The first version was proprietary, but the second is open source. It is currently implemented under all of Apple's operating systems, as well as on Linux.

Among the features of Swift are a tuple data type, an option type (variables of this type can have a special no-value value), protocols (similar to Java - interfaces), two categories of types, class and struct, which support reference types and value types, as in C#, generic types, no pointers, a safer switch - construct, in which the default is to not fall through to the next option, and all statement collections, including a single statement, must be enclosed in braces in all control constructs.

Statements need not be terminated with semicolons, unless there are two or more statements on the same line. Types of data need not be declared, as type inferencing is used. Unlike C and C++, assignment statements do not return a value, so using `x = 0` is not legal in a Boolean expression. This eliminates a common error in C and C++ programs, in which `x = 0` is typed instead of `x == 0`. Heap allocated objects are automatically reclaimed, using reference counters.

Swift programs can interact with Objective-C code and Swift uses the same libraries as that language. Swift is already the tenth most popular programming language, according to the TIOBE Community Report.

2.16.5 Another Related Language: Delphi

Delphi (Lischner, 2000) is a hybrid language, similar to C++ and Objective-C, in that it was created by adding object-oriented support, among other things, to an existing imperative language, in this case Pascal. Apple designed an object-oriented version of Pascal, named Object Pascal, but subsequently dropped the project. Borland, which had developed Turbo Pascal for Windows, also designed an object-oriented version of Pascal, based on Turbo Pascal, also named Object Pascal. For several reasons, Borland renamed Object Pascal as Delphi. The first product with that name, which included an integrated development environment (IDE), was released in 1995. Some consider the IDE to be Delphi and the underlying programming language to be Object Pascal. Other suppliers of similar products continue to refer to the language as Object Pascal.

Many of the differences between C++ and Delphi are a result of the predecessor language and the surrounding programming cultures from which they are derived. Because C is a powerful but potentially unsafe language, C++ also fits that description, at least in the areas of array subscript range checking, pointer arithmetic, and its numerous type coercions. Similarly, because Pascal is more elegant and safer than C, Delphi is more elegant and safer than C++. Delphi is also less complex than C++. For example, Delphi does not include user-defined operator overloading, generic subprograms, and parameterized classes, all of which are part of C++.

Delphi was designed by Anders Hejlsberg, who had previously developed the Turbo Pascal system. Hejlsberg, who moved to Microsoft in 1996, was the lead designer of C#.

2.17 An Imperative-Based Object-Oriented Language: Java

Java's designers started with C++, removed some constructs, changed some, and added a few others. The resulting language provides much of the power and flexibility of C++, but in a smaller, simpler, and safer language. Since that initial design, Java has grown considerably.

2.17.1 Design Process

Java, like many programming languages, was designed for an application for which there appeared to be no satisfactory existing language. In 1990, Sun Microsystems determined there was a need for a programming language for embedded consumer electronic devices, such as toasters, microwave ovens, and interactive TV systems. Reliability was one of the primary goals for such a language. It may not seem that reliability would be an important factor in the software for a microwave oven. If an oven had malfunctioning software, it probably would not pose a grave danger to anyone and most likely would not lead to large legal settlements. However, if the software in a particular model was found to be erroneous after a million units had been manufactured and sold, their recall would entail significant cost. Therefore, reliability *is* an important characteristic of the software in consumer electronic products.

After considering C and C++, it was decided that neither would be satisfactory for developing software for consumer electronic devices. Although C was relatively small, it did not provide support for object-oriented programming, which they deemed a necessity. C++ supported object-oriented programming, but it was judged to be too large and complex, in part because it also supported procedure-oriented programming. It was also believed that neither C nor C++ provided the necessary level of reliability. So, a new language, later named Java, was designed. Its design was guided by the fundamental goal of providing greater simplicity and reliability than

C++ was believed to provide.

Although the initial impetus for Java was consumer electronics, none of the products with which it was used in its early years were ever marketed. Starting in 1993, when the World Wide Web became widely used, and largely because of the new graphical browsers, Java was found to be a useful tool for Web programming. In particular, Java applets, which are relatively small Java programs that are interpreted in Web browsers and whose output can be included in displayed Web documents, quickly became very popular in the middle to late 1990s. In the first few years of Java popularity, the Web was its most common application.

The Java design team was headed by James Gosling, who had previously designed the UNIX emacs editor and the NeWS windowing system.

2.17.2 Language Overview

As we stated previously, Java is based on C++ but it was specifically designed to be smaller, simpler, and more reliable. Like C++, Java has both classes and primitive types. Java arrays are instances of a predefined class, whereas in C++ they are not, although many C++ users build wrapper classes for arrays to add features like index range checking, which is implicit in Java.

Java does not have pointers, but its reference types provide some of the capabilities of pointers. These references are used to point to class instances. All objects are allocated on the heap. References are always implicitly dereferenced, when necessary. So they behave more like ordinary scalar variables.

Java has a primitive Boolean type named **`boolean`**, used mainly for the control expressions of its control statements (such as **`if`** and **`while`**). Unlike C and C++, arithmetic expressions cannot be used for control expressions.

One significant difference between Java and many of its predecessors that support object-oriented programming, including C++, is that it is not possible to write stand-alone subprograms in Java. All Java subprograms are methods

and are defined in classes. Furthermore, methods can be called through a class or object only. One consequence of this is that while C++ supports both procedural and object-oriented programming, Java supports object-oriented programming only.

Another important difference between C++ and Java is that C++ supports multiple inheritance directly in its class definitions. Java supports only single inheritance of classes, although some of the benefits of multiple inheritance can be gained by using its interface construct.

Among the C++ constructs that were not copied into Java are structs and unions.

Java includes a relatively simple form of concurrency control through its **`synchronized`** modifier, which can appear on methods and blocks. In either case, it causes a lock to be attached. The lock ensures mutually exclusive access or execution. In Java, it is relatively easy to create concurrent processes, which in Java are called *threads*.

Java uses implicit storage deallocation for its objects, often called **garbage collection**. This frees the programmer from needing to delete objects explicitly when they are no longer needed. Programs written in languages that do not have garbage collection often suffer from what is sometimes called memory leakage, which means that storage is allocated but never deallocated. This can obviously lead to eventual depletion of all available storage. Object deallocation is discussed in detail in Chapter 6.

Unlike C and C++, Java includes assignment type coercions (implicit type conversions) only if they are widening (from a “smaller” type to a “larger” type). So **`int`** to **`float`** coercions are done across the assignment operator, but **`float`** to **`int`** coercions are not.

2.17.3 Evaluation

The designers of Java did well at trimming the excess and/or unsafe features of C++. For example, the elimination of half of the assignment coercions that

are done in C++ was clearly a step toward higher reliability. Index range checking of array accesses also makes the language safer. The addition of concurrency enhances the range of applications that can be written in the language, as do the class libraries for graphical user interfaces, database access, and networking.

Java's portability, at least in intermediate form, has often been attributed to the design of the language, but it is not. Any language can be translated to an intermediate form and "run" on any platform that has a virtual machine for that intermediate form. The price of this kind of portability is the cost of interpretation, which traditionally has been about an order of magnitude more than execution of machine code. The initial version of the Java interpreter, called the Java Virtual Machine (JVM), indeed was at least 10 times slower than equivalent compiled C programs. However, many Java programs are now translated to machine code before being executed, using Just-in-Time (JIT) compilers. This makes the efficiency of Java programs competitive with that of programs in conventionally compiled languages such as C++, at least when array index range checking is not considered.

The use of Java increased faster than that of any other programming language. Initially, this was due to its value in programming dynamic Web documents. Clearly, one of the reasons for Java's rapid rise to prominence is simply that programmers like its design. Some developers thought C++ was too large and complex to be practical and safe. Java offered them an alternative that has much of the power of C++, but in a simpler, safer language. Another reason is that the compiler/interpreter system for Java is free and easily obtained on the Web. Java is now widely used in a variety of different applications areas.

The most recent version of Java, Java SE8, appeared in 2014. Since the first version, significant features have been added to the language. Among these are an enumeration class, generics, a new iteration construct, lambda expressions, and numerous class libraries.

The following is an example of a Java program:

```
// Java Example Program
// Input:   An integer, listlen, where listlen is less
```

```
//          than 100, followed by length-integer values
// Output:  The number of input data that are greater than
//          the average of all input values
import java.io.*;
class IntSort {
public static void main(String args[]) throws IOException {
  DataInputStream in = new DataInputStream(System.in);
  int listlen,
      counter,
      sum = 0,
      average,
      result = 0;
  int[] intlist =  new int[99];
  listlen = Integer.parseInt(in.readLine());
  if ((listlen > 0) && (listlen < 100)) {
/* Read input into an array and compute the sum */
    for (counter = 0; counter < listlen; counter++) {
      intlist[counter] =
             Integer.valueOf(in.readLine()).intValue();
      sum += intlist[counter];
    }
/* Compute the average */
    average = sum / listlen;
/* Count the input values that are > average */
    for (counter = 0; counter < listlen; counter++)
      if (intlist[counter] > average) result++;
/* Print result */
      System.out.println(
          "\nNumber of values > average is:" + result);
    } //** end of then clause of if ((listlen > 0) ...
    else System.out.println(
              "Error-input list length is not legal\n");
  } //** end of method main
} //** end of class IntSort
```

2.18 Scripting Languages

Scripting languages have evolved over the past 35 years. Early scripting - languages were used by putting a list of commands, called a **script**, in a file to be interpreted. The first of these languages, named `sh` (for shell), began as a small collection of commands that were interpreted as calls to system subprograms that performed utility functions, such as file management and simple file filtering. To this were added variables, control flow statements, functions, and various other capabilities, and the result is a complete programming language. One of the most powerful and widely known of these is `ksh` (Bolsky and Korn, 1995), which was developed by David Korn at Bell Laboratories.

Another scripting language is `awk`, developed by Al Aho, Brian Kernighan, and Peter Weinberger at Bell Laboratories (Aho et al., 1988). `awk` began as a report-generation language but later became a more general-purpose language.

2.18.1 Origins and Characteristics of Perl

The Perl language, developed by Larry Wall, was originally a combination of `sh` and `awk`. Perl has grown significantly since its beginnings and is now a powerful, although still somewhat primitive, programming language. Although it is still often called a scripting language, it is actually more similar to a typical imperative language, since it is always compiled, at least into an intermediate language, before it is executed. Furthermore, it has all the constructs to make it applicable to a wide variety of areas of computational problems.

Perl has a number of interesting features, only a few of which are mentioned in this chapter and discussed later in the book.

Variables in Perl are statically typed and implicitly declared. There are three distinctive namespaces for variables, denoted by the first character of the variables' names. All scalar variable names begin with dollar signs (`$`), all array names begin with at signs (`@`), and all hash names (hashes are briefly described below) begin with percent signs (`%`). This convention makes variable names in programs more readable than those of most other programming languages.

Perl includes a large number of implicit variables. Some of them are used to store Perl parameters, such as the particular form of newline character or characters that are used in the implementation. Implicit variables are commonly used as default parameters to built-in functions and default operands for some operators. The implicit variables have distinctive—although cryptic—names, such as `$!` and `@_`. The implicit variables' names, like the user-defined variable names, use the three namespaces, so `$!` is the name of a scalar variable.

Perl's arrays have two characteristics that set them apart from the arrays of the common imperative languages. First, they have dynamic length, meaning that they can grow and shrink as needed during execution. Second, arrays can be sparse, meaning that there can be gaps between the elements. These gaps do not take space in memory, and the iteration statement used for arrays, **`foreach`**, iterates over the missing elements.

Perl includes associative arrays, which are called **hashes**. These data structures are indexed by strings and are implicitly controlled hash tables. The Perl system supplies the hash function and increases the size of the structure when necessary.

Perl is a powerful, but somewhat dangerous, language. Its scalar type stores both strings and numbers, which are normally stored in double-precision - floating-point form. Depending on the context, numbers may be coerced to strings and vice versa. If a string is used in numeric context and the string cannot be converted to a number, zero is used and there is no warning or error message provided for the user. This can lead to errors that are not detected by the compiler or run-time system. Array indexing cannot be checked, because there is no set subscript range for any array. References to nonexistent elements return **`undef`**, which is interpreted as zero in numeric

context. So, there is also no error detection in array element access.

Perl's initial use was as a UNIX utility for processing text files. It was and still is widely used as a UNIX system administration tool. When the World Wide Web appeared, Perl achieved widespread use as a common gateway interface language for use with the Web, although it is now rarely used for that purpose. Perl is used as a general-purpose language for a variety of applications, such as computational biology and artificial intelligence.

The following is an example of a Perl program:

```
# Perl Example Program
# Input:   An integer, $listlen, where $listlen is less
#          than 100, followed by $listlen-integer values.
# Output:  The number of input values that are greater than
#          the average of all input values.
($sum, $result) = (0, 0);
$listlen = <STDIN>;
if (($listlen > 0) && ($listlen < 100)) {
# Read input into an array and compute the sum
  for ($counter = 0; $counter < $listlen; $counter++) {
    $intlist[$counter] = <STDIN>;
  } #- end of for (counter ...
# Compute the average
  $average = $sum / $listlen;
# Count the input values that are > average
  foreach  $num (@intlist) {
    if ($num > $average) { $result++; }
  } #- end of foreach $num ...
# Print result
  print "Number of values > average is: $result \n";
} #- end of if (($listlen ...
else {
  print "Error--input list length is not legal \n";
}
```

2.18.2 Origins and Characteristics of JavaScript

Use of the Web exploded in the mid-1990s after the first graphical browsers

appeared. The need for computation associated with HTML documents, which by themselves are completely static, quickly became critical. Computation on the server side was made possible with the common gateway interface (CGI), which allowed HTML documents to request the execution of programs on the server, with the results of such computations returned to the browser in the form of HTML documents. Computation on the browser end became available with the advent of Java applets. Both of these approaches have now been replaced for the most part by newer technologies, primarily scripting languages.

JavaScript was originally developed by Brendan Eich at Netscape. Its original name was Mocha. It was later renamed LiveScript. In late 1995, LiveScript became a joint venture of Netscape and Sun Microsystems and its name was changed to JavaScript. JavaScript has gone through extensive evolution, moving from version 1.0 to version 1.5 by adding many new features and capabilities. A language standard for JavaScript was developed in the late 1990s by the European Computer Manufacturers Association (ECMA) as ECMA-262. This standard has also been approved by the International Standards Organization (ISO) as ISO-16262. Microsoft's version of JavaScript is named JScript .NET.

Although a JavaScript interpreter could be embedded in many different applications, its most common use is embedded in Web browsers. JavaScript code is embedded in HTML documents and interpreted by the browser when the documents are displayed. The primary uses of JavaScript in Web programming are to validate form input data and create dynamic HTML documents.

In spite of its name, JavaScript is related to Java only through the use of similar syntax. Java is strongly typed, but JavaScript is dynamically typed (see Chapter 5). JavaScript's character strings and its arrays have dynamic length. Because of this, array indices are not checked for validity, although this is required in Java. Java fully supports object-oriented programming, but JavaScript supports neither inheritance nor dynamic binding of method calls to methods.

One of the most important uses of JavaScript is for dynamically creating and modifying HTML documents. JavaScript defines an object hierarchy that

matches a hierarchical model of an HTML document, which is defined by the Document Object Model. Elements of an HTML document are accessed through these objects, providing the basis for dynamic control of the elements of documents.

Following is a JavaScript script for the problem previously solved in several languages in this chapter. Note that it is assumed that this script will be called from an HTML document and interpreted by a Web browser.

```
// example.js
//   Input:  An integer, listLen, where listLen is less
//           than 100, followed by listLen-numeric values
// Output:   The number of input values that are greater
//           than the average of all input values
var intList = new Array(99);
var listLen, counter, sum = 0, result = 0;
listLen = prompt (
        "Please type the length of the input list", "");
if ((listLen > 0) && (listLen < 100)) {
// Get the input and compute its sum
   for (counter = 0; counter < listLen; counter++) {
        intList[counter] = prompt (
                         "Please type the next number", "");
        sum += parseInt(intList[counter]);
   }
// Compute the average
   average = sum / listLen;
// Count the input values that are > average
   for (counter = 0; counter < listLen; counter++)
       if (intList[counter] > average) result++;
// Display the results
   document.write("Number of values > average is: ",
                  result, "<br />");
}  else
    document.write(
       "Error - input list length is not legal <br />");
```

2.18.3 Origins and Characteristics of PHP

PHP (Tatroe et al., 2013) was developed by Rasmus Lerdorf, an employee of

the Apache Group, in 1994. His initial motivation was to provide a tool to help track visitors to his personal Web site. In 1995, he developed a package called Personal Home Page Tools, which became the first publicly distributed version of PHP. Originally, PHP was an abbreviation for Personal Home Page. Later, its user community began using the recursive name PHP: Hypertext Preprocessor, which subsequently forced the original name into obscurity. PHP is now developed, distributed, and supported as an open-source product. PHP processors are resident on most Web servers.

PHP is an HTML-embedded server-side scripting language specifically designed for Web applications. PHP code is interpreted on the Web server when an HTML document in which it is embedded has been requested by a browser. PHP code usually produces HTML code as output, which replaces the PHP code in the HTML document. Therefore, a Web browser never sees PHP code.

PHP is similar to JavaScript in its syntactic appearance, the dynamic nature of its strings and arrays, and its use of dynamic typing. PHP's arrays are a combination of JavaScript's arrays and Perl's hashes.

The original version of PHP did not support object-oriented programming. Abstract classes, interfaces, destructors, and access controls for class members have since been added to the language.

PHP allows simple access to HTML form data, so form processing is easy with PHP. PHP provides support for many different database management systems. This makes it a useful language for building programs that need Web access to databases.

The current version of PHP is 7, released in 2015.

2.18.4 Origins and Characteristics of Python

Python (Lutz, 2013) is an object-oriented interpreted scripting language. Its

initial design was by Guido van Rossum at Stichting Mathematisch Centrum in the Netherlands in the early 1990s. Its development is being continued by the Python Software Foundation. Python is being used for the same kinds of applications as Perl: system administration and other relatively small computing tasks. Python is an open-source system that is available for most common computing platforms. The Python implementation is available at `www.python.org`, which also has extensive information regarding Python.

Python's syntax is not based directly on any commonly used language. It is type checked, but dynamically typed. Instead of arrays, Python includes three kinds of data structures: lists; immutable lists, which are called **tuples**; and hashes, which are called **dictionaries**. There is a collection of list methods, such as `append`, `insert`, `remove`, and `sort`, as well as a collection of methods for dictionaries, such as `keys`, `values`, `copy`, and `has_key`. Python also supports list comprehensions, which originated with the Haskell language. List comprehensions are discussed in Section 15.8.

Python is object oriented, includes the pattern-matching capabilities of Perl, and has exception handling. Garbage collection is used to reclaim objects when they are no longer needed.

Support for form processing is provided by the `cgi` module. Modules that support cookies, networking, and database access are also available.

Python includes support for concurrency with its threads, as well as support for network programming with its sockets. It also has more support for functional programming than other nonfunctional programming languages.

One of the more interesting features of Python is that it can be easily extended by any user. The modules that support the extensions can be written in any compiled language. Extensions can add functions, variables, and object types. These extensions are implemented as additions to the Python interpreter.

2.18.5 Origins and Characteristics

of Ruby

Ruby (Thomas et al., 2005) was designed by Yukihiro Matsumoto (aka Matz) in the early 1990s and released in 1996. Since then it has continually evolved. The motivation for Ruby was dissatisfaction of its designer with Perl and Python. Although both Perl and Python support object-oriented programming,14 neither is a pure object-oriented language, at least in the sense that each has primitive (nonobject) types and each supports functions.

14. Actually, Python's support for object-oriented programming is partial.

The primary characterizing feature of Ruby is that it is a pure object-oriented language, just as is Smalltalk. Every data value is an object and all operations are via method calls. The operators in Ruby are only syntactic mechanisms to specify method calls for the corresponding operations. Because they are methods, they can be redefined. All classes, predefined or user defined, can be subclassed.

Both classes and objects in Ruby are dynamic in the sense that methods can be dynamically added to either. This means that both classes and objects can have different sets of methods at different times during execution. So, different instantiations of the same class can behave differently. Collections of methods, data, and constants can be included in the definition of a class.

The syntax of Ruby is related to that of Eiffel and Ada. There is no need to declare variables, because dynamic typing is used. The scope of a variable is specified in its name: A variable whose name begins with a letter has local scope; one that begins with `@` is an instance variable; one that begins with `$` has global scope. A number of features of Perl are present in Ruby, including implicit variables with silly names, such as `$_`.

As is the case with Python, any user can extend and/or modify Ruby. Ruby is culturally interesting because it is the first programming language designed in Japan that has achieved relatively widespread use in the United States.

2.19 The Flagship .NET Language: C#

C#, along with the development platform .NET,15 was announced by Microsoft in 2000. In January 2002, production versions of both were released.

15. The .NET development system is briefly discussed in Chapter 1.

2.19.1 Design Process

C# is based on C++ and Java but includes some ideas from Delphi and Visual Basic. Its lead designer, Anders Hejlsberg, also designed Turbo Pascal and -Delphi, which explains the Delphi parts of the heritage of C#.

The purpose of C# is to provide a language for component-based software development, specifically for such development in the .NET Framework. In this environment, components from a variety of languages easily can be combined to form systems. All of the .NET languages, which include C#, VB.NET, Managed C++, F#, and JScript .NET,16 use the common type system (CTS). The CTS provides a common class library. All types in all five .NET languages inherit from a single class root, `System.Object`. Compilers that conform to the CTS specification create objects that can be combined into software systems. All .NET languages are compiled into the same intermediate form, Intermediate Language (IL).17 Unlike Java, however, the IL is never interpreted. A Just-in-Time compiler is used to translate IL into machine code before it is executed.

16. Many other languages have been modified to be .NET languages.

17. Initially, IL was called MSIL (Microsoft Intermediate Language), but apparently many people thought that name was too long.

2.19.2 Language Overview

Many believe that one of Java's most important advances over C++ lies in the fact that it excludes some of C++'s features. For example, C++ supports multiple inheritance, pointers, structs, **`enum`** types, operator overloading, and a goto statement, but Java includes none of these. The designers of C# obviously disagreed with this wholesale removal of features, because all of these except multiple inheritance have been included in C#.

To the credit of C#'s designers, however, in several cases, the C# version of a C++ feature has been improved. For example, the **enum** types of C# are safer than those of C++, because they are never implicitly converted to integers. This allows them to be more type safe. The **struct** type was changed significantly, resulting in a truly useful construct, whereas in C++ it serves virtually no purpose. C#'s structs are discussed in Chapter 12. C# takes a stab at improving the **switch** statement that is used in C, C++, and Java. C#'s switch is discussed in Chapter 8.

Although C++ includes function pointers, they share the lack of safety that is inherent in C++'s pointers to variables. C# includes a new type, delegates, which are both object-oriented and type-safe references to subprograms. Delegates are used for implementing event handlers, controlling the execution of threads, and callbacks.18 Callbacks are implemented in Java with interfaces; in C++, method pointers are used.

18. When an object calls a method of another object and needs to be notified when that method has completed its task, the called method calls its caller back. This is known as a callback.

In C#, methods can take a variable number of parameters, as long as they are all the same type. This is specified by the use of a formal parameter of array type, preceded by the **`params`** reserved word.

Both C++ and Java use two distinct typing systems: one for primitives and one for objects. In addition to being confusing, this leads to a frequent need to convert values between the two systems—for example, to put a primitive

value into a collection that stores objects. C# makes the conversion between values of the two typing systems partially implicit through the implicit boxing and unboxing operations, which are discussed in detail in Chapter 12.19

19. This feature was added to Java in Java 5.0.

Among the other features of C# are rectangular arrays, which are not supported in most programming languages, and a **`foreach`** statement, which is an iterator for arrays and collection objects. A similar **`foreach`** statement is found in Perl, PHP, and Java 5.0. Also, C# includes properties, which are an alternative to public data members. Properties are specified as data members with get and set methods, which are implicitly called when references and assignments are made to the associated data members.

C# has evolved continuously and quickly from its initial release in 2002. The most recent version is C# 7.0. New in C# 7.0 are tuples and a form of pattern matching.

2.19.3 Evaluation

C# was meant to be an improvement over both C++ and Java as a general--purpose programming language. Although it can be argued that some of its features are a step backward, C# includes some constructs that move it beyond its predecessors. Some of its features will surely be adopted by other programming languages of the future.

The following is an example of a C# program:

```
// C# Example Program
// Input:  An integer, listlen, where listlen is less than
//         100, followed by listlen-integer values.
// Output: The number of input values that are greater
//         than the average of all input values.
using System;
public class Ch2example {
  static void Main() {
    int[] intlist;
```

```
    int listlen,
        counter,
        sum = 0,
        average,
        result = 0;
    intList = new int[99];
    listlen = Int32.Parse(Console.readLine());
    if ((listlen > 0) && (listlen < 100)) {
// Read input into an array and compute the sum
      for (counter = 0; counter < listlen; counter++) {
        intList[counter] =
                        Int32.Parse(Console.readLine());
        sum += intList[counter];
      } //- end of for (counter ...
// Compute the average
      average = sum / listlen;
// Count the input values that are > average
      foreach (int num in intList)
        if (num > average) result++;
// Print result
      Console.WriteLine(
         "Number of values > average is:" + result);
    } //- end of if ((listlen ...
    else
      Console.WriteLine(
         "Error--input list length is not legal");
  } //- end of method Main
} //- end of class Ch2example
```

2.20 Markup-Programming Hybrid Languages

A markup-programming hybrid language is a markup language in which some of the elements can specify programming actions, such as control flow and computation. The following subsections introduce two such hybrid languages, XSLT and JSP.

2.20.1 XSLT

eXtensible markup language (XML) is a metamarkup language. Such a language is used to define markup languages. XML-derived markup languages are used to define XML data documents. Although XML documents are human readable, they are processed by computers. This processing sometimes consists only of transformations to alternative forms that can be effectively displayed or printed. In many cases, such transformations are to HTML, which can be displayed by a Web browser. In other cases, the data in the document is processed, just as with other forms of data files.

The transformation of XML documents to HTML documents is specified in another markup language, eXtensible stylesheet language transformations (XSLT) (`www.w3.org/TR/XSLT`). XSLT can specify programming-like operations. Therefore, XSLT is a markup-programming hybrid language. XSLT was defined by the World Wide Web Consortium (W3C) in the late 1990s.

An XSLT processor is a program that takes as input an XML data document and an XSLT document (which is also in the form of an XML document). In this processing, the XML data document is transformed to another XML document,20 using the transformations described in the XSLT document. The XSLT document specifies transformations by defining templates, which are

data patterns that could be found by the XSLT processor in the XML input file. Associated with each template in the XSLT document are its transformation instructions, which specify how the matching data is to be transformed before being put in the output document. So, the templates (and their associated processing) act as subprograms, which are “executed” when the XSLT processor finds a pattern match in the data of the XML document.

20. The output document of the XSLT processor could also be in HTML or plain text.

XSLT also has programming constructs at a lower level. For example, a looping construct is included, which allows repeated parts of the XML document to be selected. There is also a sort process. These lower-level constructs are specified with XSLT tags, such as `<for-each>`.

2.20.2 JSP

The “core” part of the Java Server Pages Standard Tag Library (JSTL) is another markup-programming hybrid language, although its form and purpose are different from those of XSLT. Before discussing JSTL, it is necessary to introduce the ideas of servlets and Java Server Pages (JSP). A **servlet** is an instance of a Java class that resides on and is executed on a Web server system. The execution of a servlet is requested by a markup document being displayed by a Web browser. The servlet’s output, which is in the form of an HTML document, is returned to the requesting browser. A program that runs in the Web server process, called a **servlet container**, controls the execution of servlets. Servlets are commonly used for form processing and for database access.

JSP is a collection of technologies designed to support dynamic Web documents and provide other processing needs of Web documents. When a JSP document, which is often a mixture of HTML and Java, is requested by a browser, the JSP processor program, which resides on a Web server system, converts the document to a servlet. The document’s embedded Java code is copied to the servlet. The plain HTML is copied into Java print statements that output it as is. The JSTL markup in the JSP document is processed, as

discussed in the following paragraph. The servlet produced by the JSP processor is run by the servlet container.

The JSTL defines a collection of XML action elements that control the processing of the JSP document on the Web server. These elements have the same form as other elements of HTML and XML. One of the most commonly used JSTL control action elements is `if`, which specifies a Boolean expression as an attribute.21 The content of the `if` element (the text between the opening tag (`<if>`) and its closing tag (`</if>`)) is HTML code that will be included in the output document only if the Boolean expression evaluates to true. The `if` element is related to the C/C++ `#if` preprocessor command. The JSP container processes the JSTL parts of JSP documents in a way that is similar to how the C/C++ preprocessor processes C and C++ programs. The preprocessor commands are instructions for the preprocessor to specify how the output file is to be constructed from the input file. Similarly, JSTL control action elements are instructions for the JSP processor to specify how to build the XML output file from the XML input file.

21. An attribute in HTML, which is embedded in the opening tag of an element, provides further information about that element.

One common use of the `if` element is for the validation of form data submitted by a browser user. Form data is accessible by the JSP processor and can be tested with the `if` element to ensure that it is sensible data. If not, the `if` element can insert an error message for the user in the output document.

For multiple selection control, JSTL has `choose`, `when`, and `otherwise` elements. JSTL also includes a `forEach` element, which iterates over collections, which typically are form values from a client. The `forEach` element can include `begin`, `end`, and `step` attributes to control its iterations.

SUMMARY

We have investigated the development of a number of programming languages. This chapter gives the reader a good perspective on current issues in language design. We have set the stage for an in-depth discussion of the important features of contemporary languages.

BIBLIOGRAPHIC NOTES

Perhaps the most important source of historical information about the development of early programming languages is *History of Programming Languages*, edited by Richard Wexelblat (1981). It contains the developmental background and environment of 13 important programming languages, as told by the designers themselves. A similar work resulted from a second "history" conference, published as a special issue of *ACM SIGPLAN Notices* (ACM, 1993a). In this work, the history and evolution of 13 more programming languages are discussed.

The paper "Early Development of Programming Languages" (Knuth and Pardo, 1977), which is part of the *Encyclopedia of Computer Science and Technology*, is an excellent 85-page work that details the development of languages up to and including Fortran. The paper includes example programs to demonstrate the features of many of those languages.

Another book of great interest is *Programming Languages: History and - Fundamentals*, by Jean Sammet (1969). It is a 785-page work filled with details of 80 programming languages of the 1950s and 1960s. Sammet has also published several updates to her book, such as *Roster of Programming Languages for 1974–75* (1976).

REVIEW QUESTIONS

1. In what year was Plankalkül designed? In what year was that design published?

2. What two common data structures were included in Plankalkül?

3. How were the pseudocodes of the early 1950s implemented?

4. Speedcoding was invented to overcome two significant shortcomings of the computer hardware of the early 1950s. What were they?

5. Why was the slowness of interpretation of programs acceptable in the early 1950s?

6. What hardware capability that first appeared in the IBM 704 computer strongly affected the evolution of programming languages? Explain why.

7. In what year was the Fortran design project begun?

8. What was the primary application area of computers at the time Fortran was designed?

9. What was the source of all of the control flow statements of Fortran I?

10. What was the most significant feature added to Fortran I to get Fortran II?

11. What control flow statements were added to Fortran IV to get Fortran 77?

12. Which version of Fortran was the first to have any sort of dynamic variables?

13. Which version of Fortran was the first to have character string handling?

14. Why were linguists interested in artificial intelligence in the late 1950s?

15. Where was Lisp developed? By whom?

16. In what way are Scheme and Common Lisp opposites of each other?

17. What dialect of Lisp is used for introductory programming courses at some universities?

18. What two professional organizations together designed ALGOL 60?

19. In what version of ALGOL did block structure appear?

20. What missing language element of ALGOL 60 damaged its chances for widespread use?

21. What language was designed to describe the syntax of ALGOL 60?

22. On what programming language was COBOL based?

23. In what year did the COBOL design process begin?

24. What data structure that appeared in COBOL originated with Plankalkül?

25. What organization was most responsible for the early success of COBOL (in terms of extent of use)?

26. What user group was the target of the first version of Basic?

27. Why was Basic an important language in the early 1980s?

28. PL/I was designed to replace what two languages?

29. For what new line of computers was PL/I designed?

30. What features of SIMULA 67 are now important parts of some object-oriented languages?

31. What innovation of data structuring was introduced in ALGOL 68 but is often credited to Pascal?

32. What design criterion was used extensively in ALGOL 68?

33. What language introduced the **`case`** statement?

34. What operators in C were modeled on similar operators in ALGOL 68?

35. What are two characteristics of C that make it less safe than Pascal?

36. What is a nonprocedural language?

37. What are the two kinds of statements that populate a Prolog database?

38. What is the primary application area for which Ada was designed?

39. What are the concurrent program units of Ada called?

40. What Ada construct provides support for abstract data types?

41. What populates the Smalltalk world?

42. What three concepts are the basis for object-oriented programming?

43. Why does C++ include the features of C that are known to be unsafe?

44. What language was Swift designed to replace?

45. What do the Ada and COBOL languages have in common?

46. What was the first application for Java?

47. What characteristic of Java is most evident in JavaScript?

48. How does the typing system of PHP and JavaScript differ from that of Java?

49. What array structure is included in C# but not in C, C++, or Java?

50. What two languages was the original version of Perl meant to replace?

51. For what application area is JavaScript most widely used?

52. What is the relationship between JavaScript and PHP, in terms of their use?

53. PHP's primary data structure is a combination of what two data structures from other languages?

54. What data structure does Python use in place of arrays?

55. What characteristic does Ruby share with Smalltalk?

56. What characteristic of Ruby's arithmetic operators makes them unique among those of other languages?

57. What deficiency of the **`switch`** statement of C is addressed with the changes made by C# to that statement?

58. What is the primary platform on which C# is used?

59. What are the inputs to an XSLT processor?

60. What is the output of an XSLT processor?

61. What element of the JSTL is related to a subprogram?

62. To what is a JSP document converted by a JSP processor?

63. Where are servlets executed?

PROBLEM SET

1. What features of Plankalkül do you think would have had the greatest influence on Fortran 0 if the Fortran designers had been familiar with Plankalkül?

2. Determine the capabilities of Backus's 701 Speedcoding system, and compare them with those of a contemporary programmable hand calculator.

3. Write a short history of the A-0, A-1, and A-2 systems designed by Grace Hopper and her associates.

4. Compare the facilities of Fortran 0 with those of the Laning and Zierler system.

5. Which of the three original goals of the ALGOL design committee, in your opinion, was most difficult to achieve at that time?

6. Make an educated guess as to the most common syntax error in Lisp programs.

7. Lisp began as a pure functional language but gradually acquired more and more imperative features. Why?

8. Describe in detail the three most important reasons, in your opinion, why ALGOL 60 did not become a very widely used language.

9. Why, in your opinion, did COBOL allow long identifiers when Fortran and ALGOL did not?

10. Outline the major motivation of IBM in developing PL/I.

11. Was IBM's assumption, on which it based its decision to develop PL/I, correct, given the history of computers and language developments since 1964?

12. Describe, in your own words, the concept of orthogonality in programming language design.

13. What is the primary reason why PL/I became more widely used than ALGOL 68?

14. What are the arguments both for and against the idea of a typeless language?

15. Are there any logic programming languages other than Prolog?

16. What is your opinion of the argument that languages that are too complex are too dangerous to use, and we should therefore keep all languages small and simple?

17. Do you think language design by committee is a good idea? Support your opinion.

18. Languages continually evolve. What sort of restrictions do you think are appropriate for changes in programming languages? Compare your answers with the evolution of Fortran.

19. Build a table identifying all of the major language developments, together with when they occurred, in what language they first appeared, and the identities of the developers.

20. There have been some public interchanges between Microsoft and Sun concerning the design of Microsoft's J++ and C# and Sun's Java. Read some of these documents, which are available on their respective Web sites, and write an analysis of the disagreements concerning the delegates.

21. In recent years data structures have evolved within scripting languages to replace traditional arrays. Explain the chronological sequence of these developments.

22. Explain two reasons why pure interpretation is an acceptable implementation method for several recent scripting languages.

23. Why, in your opinion, do new scripting languages appear more frequently than new compiled languages?

24. Give a brief general description of a markup-programming hybrid language.

PROGRAMMING EXERCISES

1. To understand the value of records in a programming language, write a small program in a C-based language that uses an array of structs that store student information, including name, age, GPA as a float, and grade level as a string (e.g., “freshmen,” etc.). Also, write the same program in the same language without using structs.

2. To understand the value of recursion in a programming language, write a program that implements quicksort, first using recursion and then without recursion.

3. To understand the value of counting loops, write a program that implements matrix multiplication using counting loop constructs. Then write the same program using only logical loops—for example, `while` loops.

3 Describing Syntax and Semantics

This chapter begins by defining the terms *syntax* and *semantics*. Then, a detailed discussion of the most common method of describing syntax, context-free grammars (also known as Backus-Naur Form), is presented. Included in this discussion are derivations, parse trees, ambiguity, descriptions of operator precedence and associativity, and extended Backus-Naur Form. Attribute grammars, which can be used to describe both the syntax and static semantics of programming languages, are discussed next. In the last section, three formal methods of describing semantics—operational, axiomatic, and denotational semantics—are introduced. Because of the inherent complexity of the semantics description methods, our discussion of them is brief. One could easily write an entire book on just one of the three (as several authors have).

3.1 Introduction

The task of providing a concise yet understandable description of a programming language is difficult but essential to the language's success. ALGOL 60 and ALGOL 68 were first presented using concise formal descriptions; in both cases, however, the descriptions were not easily understandable, partly because each used a new notation. The levels of acceptance of both languages suffered as a result. On the other hand, some languages have suffered the problem of having many slightly different dialects, a result of a simple but informal and imprecise definition.

One of the problems in describing a language is the diversity of the people who must understand the description. Among these are initial evaluators, implementors, and users. Most new programming languages are subjected to a period of scrutiny by potential users, often people within the organization that employs the language's designer, before their designs are completed. These are the initial evaluators. The success of this feedback cycle depends heavily on the clarity of the description.

Programming language implementors obviously must be able to determine how the expressions, statements, and program units of a language are formed, and also their intended effect when executed. The difficulty of the implementors' job is, in part, determined by the completeness and precision of the language description.

Finally, language users must be able to determine how to encode software solutions by referring to a language reference manual. Textbooks and courses enter into this process, but language manuals are usually the only authoritative printed information source about a language.

The study of programming languages, like the study of natural languages, can be divided into examinations of syntax and semantics. The **syntax** of a programming language is the form of its expressions, statements, and - program units. Its **semantics** is the meaning of those expressions, statements, and program units. For example, the syntax of a Java `while` statement is

- **`while`** (boolean_expr) statement

The semantics of this statement form is that when the current value of the Boolean expression is true, the embedded statement is executed. Then control implicitly returns to the Boolean expression to repeat the process. If the Boolean expression is false, control transfers to the statement following the **`while`** construct.

Although they are often separated for discussion purposes, syntax and semantics are closely related. In a well-designed programming language, semantics should follow directly from syntax; that is, the appearance of a statement should strongly suggest what the statement is meant to accomplish.

Describing syntax is easier than describing semantics, partly because a concise and universally accepted notation is available for syntax description, but none has yet been developed for semantics.

3.2 The General Problem of Describing Syntax

A language, whether natural (such as English) or artificial (such as Java), is a set of strings of characters from some alphabet. The strings of a language are called **sentences** or statements. The syntax rules of a language specify which strings of characters from the language's alphabet are in the language. English, for example, has a large and complex collection of rules for specifying the syntax of its sentences. By comparison, even the largest and most complex programming languages are syntactically very simple.

Formal descriptions of the syntax of programming languages, for simplicity's sake, often do not include descriptions of the lowest-level syntactic units. These small units are called **lexemes**. The description of lexemes can be given by a lexical specification, which is usually separate from the syntactic description of the language. The lexemes of a programming language include its numeric literals, operators, and special words, among others. One can think of programs as strings of lexemes rather than of characters.

Lexemes are partitioned into groups—for example, the names of variables, methods, classes, and so forth in a programming language form a group called *identifiers*. Each lexeme group is represented by a name, or token. So, a **token** of a language is a category of its lexemes. For example, an identifier is a token that can have lexemes, or instances, such as `sum` and `total`. In some cases, a token has only a single possible lexeme. For example, the token for the arithmetic operator symbol + has just one possible lexeme. Consider the following Java statement:

```
index = 2 * count + 17;
```

The lexemes and tokens of this statement are

Lexemes	*Tokens*
`index`	identifier
`=`	equal_sign
`2`	int_literal
`*`	mult_op
`count`	identifier
`+`	plus_op
`17`	int_literal
`;`	semicolon

The example language descriptions in this chapter are very simple, and most include lexeme descriptions.

3.2.1 Language Recognizers

In general, languages can be formally defined in two distinct ways: by **recognition** and by **generation** (although neither provides a definition that is practical by itself for people trying to learn or use a programming language). Suppose we have a language L that uses an alphabet ∑ of characters. To define L formally using the recognition method, we would need to construct a mechanism R, called a recognition device, capable of reading strings of characters from the alphabet ∑. R would indicate whether a given input string was or was not in L. In effect, R would either accept or reject the given string. Such devices are like filters, separating legal sentences from those that are incorrectly formed. If R, when fed any string of characters over ∑, accepts it only if it is in L, then R is a description of L. Because most useful languages are, for all practical purposes, infinite, this might seem like a

lengthy and ineffective process. Recognition devices, however, are not used to enumerate all of the sentences of a language—they have a different purpose.

The syntax analysis part of a compiler is a recognizer for the language the compiler translates. In this role, the recognizer need not test all possible strings of characters from some set to determine whether each is in the language. Rather, it need only determine whether given programs are in the language. In effect then, the syntax analyzer determines whether the given programs are syntactically correct. The structure of syntax analyzers, also known as parsers, is discussed in Chapter 4.

3.2.2 Language Generators

A language generator is a device that can be used to generate the sentences of a language. We can think of the generator as having a button that produces a sentence of the language every time it is pushed. Because the particular sentence that is produced by a generator when its button is pushed is unpredictable, a generator seems to be a device of limited usefulness as a language descriptor. However, people prefer certain forms of generators over recognizers because they can more easily read and understand them. By contrast, the syntax-checking portion of a compiler (a language recognizer) is not as useful a language description for a programmer because it can be used only in trial-and-error mode. For example, to determine the correct syntax of a particular statement using a compiler, the programmer can only submit a speculated version and note whether the compiler accepts it. On the other hand, it is often possible to determine whether the syntax of a particular statement is correct by comparing it with the structure of the generator.

There is a close connection between formal generation and recognition devices for the same language. This was one of the seminal discoveries in computer science, and it led to much of what is now known about formal languages and compiler design theory. We return to the relationship of generators and recognizers in the next section.

3.3 Formal Methods of Describing Syntax

This section discusses the formal language-generation mechanisms, usually called **grammars**, that are commonly used to describe the syntax of programming languages.

3.3.1 Backus-Naur Form and Context-Free Grammars

In the middle to late 1950s, two men, Noam Chomsky and John Backus, in unrelated research efforts, developed the same syntax description formalism, which subsequently became the most widely used method for programming language syntax.

3.3.1.1 Context-Free Grammars

In the mid-1950s, Noam Chomsky, a noted linguist (among other things), described four classes of generative devices or grammars that define four classes of languages (Chomsky, 1956, 1959). Two of these grammar classes, named *context-free* and *regular*, turned out to be useful for describing the syntax of programming languages. The forms of the tokens of programming languages can be described by regular grammars. The syntax of whole programming languages, with minor exceptions, can be described by context-free grammars. Because Chomsky was a linguist, his primary interest was the theoretical nature of natural languages. He had no interest at the time in the artificial languages used to communicate with computers. So it was not until later that his work was applied to programming languages.

3.3.1.2 Origins of Backus-Naur Form

Shortly after Chomsky's work on language classes, the ACM-GAMM group began designing ALGOL 58. A landmark paper describing ALGOL 58 was presented by John Backus, a prominent member of the ACM-GAMM group, at an international conference in 1959 (Backus, 1959). This paper introduced a new formal notation for specifying programming language syntax. The new notation was later modified slightly by Peter Naur for the description of ALGOL 60 (Naur, 1960). This revised method of syntax description became known as **Backus-Naur Form**, or simply **BNF**.

BNF is a natural notation for describing syntax. In fact, something similar to BNF was used by Panini to describe the syntax of Sanskrit several hundred years before Christ (Ingerman, 1967).

Although the use of BNF in the ALGOL 60 report was not immediately accepted by computer users, it soon became and is still the most popular method of concisely describing programming language syntax.

It is remarkable that BNF is nearly identical to Chomsky's generative devices for context-free languages, called **context-free grammars**. In the remainder of the chapter, we refer to context-free grammars simply as grammars. - Furthermore, the terms BNF and grammar are used interchangeably.

3.3.1.3 Fundamentals

A **metalanguage** is a language that is used to describe another language. BNF is a metalanguage for programming languages.

BNF uses abstractions for syntactic structures. A simple Java assignment statement, for example, might be represented by the abstraction <assign> (pointed brackets are often used to delimit names of abstractions). The actual definition of <assign> can be given by

- <assign> → <var> = <expression>

The text on the left side of the arrow, which is aptly called the **left-hand side** (LHS), is the abstraction being defined. The text to the right of the arrow is the definition of the LHS. It is called the **right-hand side** (RHS) and consists of some mixture of tokens, lexemes, and references to other abstractions. (Actually, tokens are also abstractions.) Altogether, the definition is called a **rule**, or **production**. In the example rule just given, the abstractions <var> and <expression> obviously must be defined for the <assign> definition to be useful.

This particular rule specifies that the abstraction <assign> is defined as an instance of the abstraction <var>, followed by the lexeme =, followed by an instance of the abstraction <expression>. One example sentence whose syntactic structure is described by the rule is

```
total = subtotal1 + subtotal2
```

The abstractions in a BNF description, or grammar, are often called **nonterminal symbols**, or simply **nonterminals**, and the lexemes and tokens of the rules are called **terminal symbols**, or simply **terminals**. A BNF description, or **grammar**, is a collection of rules.

Nonterminal symbols can have two or more distinct definitions, representing two or more possible syntactic forms in the language. Multiple definitions can be written as a single rule, with the different definitions separated by the symbol |, meaning logical OR. For example, a Java **`if`** statement can be described with the rules

- <if_stmt> → **`if`** (<logic_expr>) <stmt>
- <if_stmt> → **`if`** (<logic_expr>) <stmt> **`else`** <stmt>

or with the rule

- <if_stmt> → **`if`** (<logic_expr>) <stmt>
- | **`if`** (<logic_expr>) <stmt> **`else`** <stmt>

In these rules, <stmt> represents either a single statement or a compound statement.

Although BNF is simple, it is sufficiently powerful to describe nearly all of the syntax of programming languages. In particular, it can describe lists of similar constructs, the order in which different constructs must appear, and nested structures to any depth, and even imply operator precedence and operator associativity.

3.3.1.4 Describing Lists

Variable-length lists in mathematics are often written using an ellipsis (. . .); 1, 2, . . . is an example. BNF does not include the ellipsis, so an alternative method is required for describing lists of syntactic elements in programming languages (for example, a list of identifiers appearing on a data declaration statement). For BNF, the alternative is recursion. A rule is **recursive** if its LHS appears in its RHS. The following rules illustrate how recursion is used to describe lists:

- <ident_list> → identifier
- | identifier, <ident_list>

This defines <ident_list> as either a single token (identifier) or an identifier followed by a comma and another instance of <ident_list>. Recursion is used to describe lists in many of the example grammars in the remainder of this chapter.

3.3.1.5 Grammars and Derivations

A grammar is a generative device for defining languages. The sentences of the language are generated through a sequence of applications of the rules, beginning with a special nonterminal of the grammar called the **start symbol**. This sequence of rule applications is called a **derivation**. In a grammar for a complete programming language, the start symbol represents a complete

program and is often named <program>. The simple grammar shown in Example 3.1 is used to illustrate derivations.

EXAMPLE 3.1 A Grammar for a Small Language

- <program> → **begin** <stmt_list> **end**
- <stmt_list> → <stmt>
- | <stmt> ; <stmt_list>
- <stmt> → <var> = <expression>
- <var> → A | B | C
- <expression> → <var> + <var>
- | <var> - <var>
- | <var>

The language described by the grammar of Example 3.1 has only one statement form: assignment. A program consists of the special word **begin**, followed by a list of statements separated by semicolons, followed by the special word **end**. An expression is either a single variable or two variables separated by either a + or - operator. The only variable names in this language are A, B, and C.

A derivation of a program in this language follows:

- <program> => **begin** <stmt_list> **end**
- => **begin** <stmt> ; <stmt_list> **end**
- => **begin** <var> = <expression> ; <stmt_list> **end**

- => **begin** A = <expression> ; <stmt_list> **end**
- => **begin** A = <var> + <var> ; <stmt_list> **end**
- => **begin** A = B + <var> ; <stmt_list> **end**
- => **begin** A = B + C ; <stmt_list> **end**
- => **begin** A = B + ; <stmt> **end**
- => **begin** A = B + C ; <var> = <expression> **end**
- => **begin** A = B + C ; B = <expression> **end**
- => **begin** A = B + C ; B = <var> **end**
- => **begin** A = B + C ; B = C **end**

This derivation, like all derivations, begins with the start symbol, in this case <program>. The symbol => is read “derives.” Each successive string in the sequence is derived from the previous string by replacing one of the nonterminals with one of that nonterminal’s definitions. Each of the strings in the derivation, including <program>, is called a **sentential form**.

In this derivation, the replaced nonterminal is always the leftmost nonterminal in the previous sentential form. Derivations that use this order of replacement are called **leftmost derivations**. The derivation continues until the sentential form contains no nonterminals. That sentential form, consisting of only terminals, or lexemes, is the generated sentence.

In addition to leftmost, a derivation may be rightmost or in an order that is neither leftmost nor rightmost. Derivation order has no effect on the language generated by a grammar.

By choosing alternative RHSs of rules with which to replace nonterminals in the derivation, different sentences in the language can be generated. By exhaustively choosing all combinations of choices, the entire language can be generated. This language, like most others, is infinite, so one cannot generate *all* the sentences in the language in finite time.

Example 3.2 is another example of a grammar for part of a typical - programming language.

EXAMPLE 3.2 A Grammar for Simple Assignment Statements

- <assign> → <id> = <expr>
- <id> → A| B | C
- <expr> → <id> + <expr>
- | <id> * <expr>
- | (<expr>)
- | <id>

The grammar of Example 3.2 describes assignment statements whose right sides are arithmetic expressions with multiplication and addition operators and parentheses. For example, the statement

```
A = B * ( A + C )
```

is generated by the leftmost derivation:

- <assign> => <id> = <expr>
- => A = <expr>
- => A = <id> * <expr>
- => A = B * <expr>
- => A = B * (<expr>)
- => A = B * (<id> + <expr>)

- => A = B * (A + <expr>)
- => A = B * (A + <id>)
- => A = B * (A + C)

3.3.1.6 Parse Trees

One of the most attractive features of grammars is that they naturally describe the hierarchical syntactic structure of the sentences of the languages they define. These hierarchical structures are called **parse trees**. For example, the parse tree in Figure 3.1 shows the structure of the assignment statement derived previously.

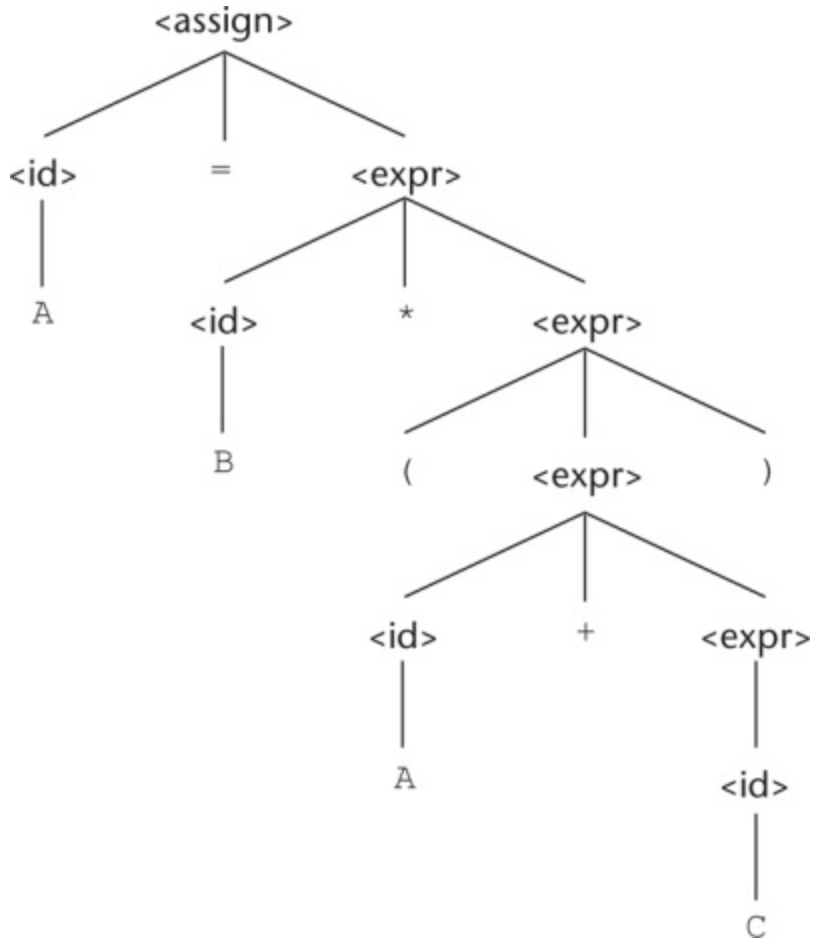

Figure 3.1 A parse tree for the simple statement `A = B * (A + C)`

Figure 3.1 Full Alternative Text

Every internal node of a parse tree is labeled with a nonterminal symbol; every leaf is labeled with a terminal symbol. Every subtree of a parse tree describes one instance of an abstraction in the sentence.

3.3.1.7 Ambiguity

A grammar that generates a sentential form for which there are two or more distinct parse trees is said to be **ambiguous**. Consider the grammar shown in Example 3.3, which is a minor variation of the grammar shown in Example 3.2.

EXAMPLE 3.3 An Ambiguous Grammar for Simple Assignment Statements

- <assign> → <id> = <expr>
- <id> → A | B | C
- <expr> → <expr> + <expr>
- | <expr> * <expr>
- | (<expr>)

- | <id>

The grammar of Example 3.3 is ambiguous because the sentence

```
A = B + C * A
```

has two distinct parse trees, as shown in Figure 3.2. The ambiguity occurs because the grammar specifies slightly less syntactic structure than does the grammar of Example 3.2. Rather than allowing the parse tree of an expression to grow only on the right, this grammar allows growth on both the left and the right.

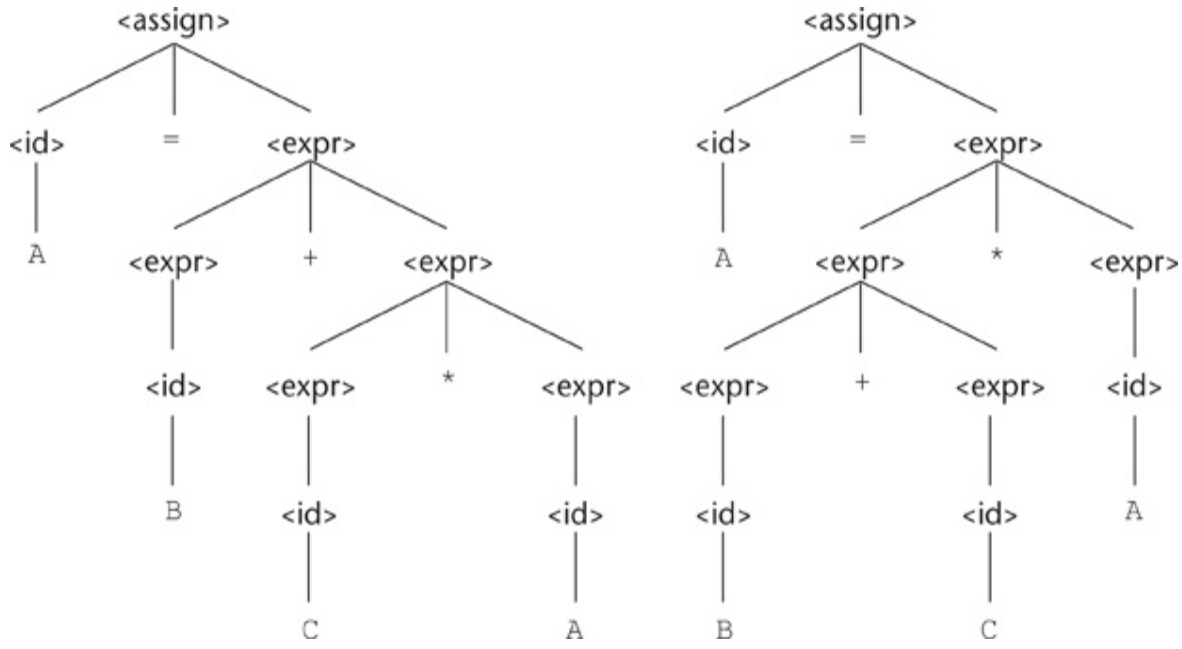

Figure 3.2 Two distinct parse trees for the same sentence, `A = B + C * A`

Figure 3.2 Full Alternative Text

Syntactic ambiguity of language structures is a problem because compilers often base the semantics of those structures on their syntactic form.

Specifically, the compiler chooses the code to be generated for a statement by examining its parse tree. If a language structure has more than one parse tree, then the meaning of the structure cannot be determined uniquely. This problem is discussed in two specific examples in the following subsections.
